Max2 (SD)	0.82 (0.24)	0.43 (0.14)	0.73 (0.18)	0.74 (0.16)	0.036 (0.030)	<0.001 (<0.001)	NS (NS)

SD – standard deviation; NS – Non significant ($p > 0.05$). *Adjusted for age, gender and ethnicity.

Table 2. Multivariate analysis of the subjects' variables influencing their CWA parameters.

Factor	Min1		Min2		Max2	
	b	p-value	b	p-value	b	p-value
Age	0.012	NS	0.003	0.043	0.002	0.029
Gender (Reference group: Female)	-0.258	NS	-0.048	NS	-0.045	NS
Ethnicity (Reference group: Non-Chinese)	-0.205	NS	-0.045	NS	-0.037	NS
Type of infection (Reference group: Control)						
Bacterial	1.453	<0.001	0.166	0.047	0.096	0.002
Dengue	-1.395	<0.001	-0.280	<0.001	-0.269	<0.001
Viral	0.443	NS	0.013	NS	-0.049	NS

Summary/Conclusion: Different types of infection modified CWA distinctively. CWA could provide information on the haemostatic milieu

triggered by infection beyond what the routine clotting time could offer and could be further evaluated as diagnostic and prognostic markers for infections.

PS1531

ANTITHROMBOTIC EFFECTS OF COMPLEX PREPARATIONS OF VEGETABLE HEPARINOID WITH LEUCINE

M. Lyapina[1,*], M. Kalugina[1]

[1]Moscow Lomonosov State University, Biological faculty, Moscow, Russian Federation

Background: In early studies, it was shown that complex preparations of high-molecular heparin(HMH) with amino acids (including leucine) have antiplatelet and anticoagulant action *in vitro* and with intravenous administration in animals [Pastorova *et al*., 1999]. The complex drugs geparinoida from the roots of Paeonia lactiflora with arginine showed anticoagulant and antiplatelet effect when administered orally to animals. In the heparinoid from the roots of this peony (Paeonia lactiflora), there were two fractions of heparin - low molecular weight heparin (LMH) by anti-factor Xa activity and HMH by anti-factor IIa activity. The correlation of these anti-IIa/anti-Xa activities averaged 1: 2,03 [Lyapina M. G. *et al*., 2017].
Aims: Creation of a complex preparation of vegetable heparinoid with leucine and testing of its antithrombotic effects in animals at oral administration in conditions thrombosis process.
Methods: A complex preparation of vegetable heparinoid from the roots of Paeonia lactiflora with leucine was obtained at a molar ratio of 1: 4, which was orally administered to an experimental group of rats at the dose of 1 mg/kg of body weight 1 h before the thrombosis process, caused by intravenous administration of threshold doses of thrombin (15 NIH) against the background of shutdown of the vegetatic nervous system by 1% aminazine (0.02 ml per 200 g of body weight). Aminazine was administered 15 minutes before the introduction of thrombin, which thus had a direct coagulating effect. Blood samples were taken 30 min after injection of thrombin. Control animals instead of the complex were injected physiological NaCl solution and the thrombin solution were also imposed on the background of 1% of chlorpromazine. In blood plasma we determined the anticoagulant activity test of activated partial thromboplastin time (APPT), platelet aggregation according to the method of Born, total fibrinolytic activity (SFA) (method idwell). Animal experiments were conducted in accordance with the ethical principles of the European Convention for the protection of vertebrates (Strasbourg, 15.06.2006).
Results: It was found that the complex preparation of vegetable heparinoid with leucine prevented the processes of thrombosis, as in the experimental group of rats platelet aggregation did not increase and remained at a normal level (100%), anticoagulant activity on the APTT test increased by 23%, SFA increased by 32%. All animals in the experiment after thrombin are alive. Another picture in the control group of rats: platelet aggregation increased by 35%, APTT and SFA decreased by 20-31% respectively. After the introduction of thrombin of from 10 control rat died three
Summary/Conclusion: Integrated drug heparinoid from the roots of Paeonia lactiflora with the amino acid leucine has in the organism of rats under conditions of high provocation of thrombosis antithrombotic effect, as evidenced by increased antiplatelet, anticoagulant and fibrinolytic activity in the plasma of experimental rats. In the control group of animals the introduced thrombin and, on the contrary, there was a suppression of platelet aggregation and a sharp decrease in anticoagulant and fibrinolytic properties of blood plasma.

PS1532

C-TERMINAL FRAGMENTS OF NEUROPEPTIDES CHANGE INTERACTION OF BLOOD CELLS IN THROMBOGENESIS

M. Golubeva[1,*]

[1]Biological Fac. Lab.of blood coagulation, Moscow State University, Moscow, Russian Federation

Background: In the process of thrombosis during therapy with antiplatelet agents, it should be borne in mind that red blood cells (RBC) can significantly increase platelet aggregation, thereby reducing the effectiveness of antiplatelet agents. The search for new drugs with a wide range of effects on the hemostatic system with minimal side effects made the researchers pay attention to the proteolysis products of neuropeptides, such as vasopressin and oxytocin. A significant effect of these peptides on platelet aggregation induced by ADP, fibrinolysis, tissue activator activity of plasminogen, etc. has been established. However, these studies do not affect all aspects the interaction of blood cells and effect of these peptides on the processes of thrombus formation with adrenaline-mediated aggregation, which was the purpose of this study.
Aims: The aim of this study was to compare the effect of small regulatory peptides, which are fragments of neurohormones, in *in vitro* experiments on the interaction of erythrocytes with platelets when they are aggregated under the influence of adrenaline.
Methods: Experiments were carried out on white mongrel male rats weighing 180-200 g body. We are using peptides representing the C-terminal fragments of vasopressin, oxytocin: - Pro-Arg-Gly-NH2.-Vasopressin fragment, (P1), - Pro-Leu-Gly-NH2 - fragment oxytocin(P2); - Platelet aggregation was measured in by adding epinephrin at a final concentration of 0.02 mmol. in platelet –rich plasma PRP, PRP+эритроциты, wash platelet + erythrocytes by addition P1 , P2 or 0,85% NaCl. Aggregation was recorded on an aggregometer (Moscow State University). The results were treated statistically. All experiments were conducted in accordance with the ethical principles and normative documents recommended by the European Science Foundation (ESF) and the Declaration on Humane Treatment of Animals.
Results: *In vitro*, peptides at a concentration of 10-4 -10-6M were added to either PRP or a mixture of PRP + RBC. It was shown that peptide P1 significantly reduced platelet aggregation (on 15% $p<0.001$). When adding red blood cells to PRP, there was an increase in platelet aggregation (on 17%). Addition of peptide P1 to this mixture caused a decrease in platelet aggregation on 24% ($p<0.001$), the decrease being stronger than in the former case. Peptide P2 was added to the PRP, there was no change in the platelet aggregation. Erythrocytes increased platelet aggregation by 8.5%. Against this background, the addition of the peptide also reduced platelet aggregation by 6.5%, ($p>0.1$), i.e. the aggregation is practically unchanged. When peptides were added to washed platelets and erythrocytes in the presence of calcium ions, P1 reduced platelet aggregation by 33.8%. The addition of erythrocytes to a mixture of erythrocytes and platelets led to an increase in aggregation of the latter by 74%. Against this background, the peptide caused a decrease in aggregation by 21%. P2 caused an increase in platelet aggregation by 52%, and the addition of the peptide to the cell mixture did not change the platelet aggregation.
Summary/Conclusion: C-terminal fragment of vasopressin has a more pronounced antiaggregant effect than the oxytocin fragment. The use of small regulatory peptides can reduce the aggregation effect of red blood cells, thereby improving therapy for thrombotic complications.

PS1533

COMPARATIVE STUDY OF DALTEPARIN SODIUM AND ACETYLSALICYLIC ACID IN PREVENTION OF ANTIPHOSPHOLID SYNDROM ASSOTIATED WITH RECURRENT PREGNANCY MISCARRIAGE

D. Marinitch[1,*]

[1]Consultative, Minsk Consultative Diagnostic Center, Minsk, Belarus

Background: Miscarriage or early pregnancy loss is the termination of pregnancy before 20 weeks' gestation or with a fetal weight of below 500 g. Recurrent pregnancy miscarriage (RPM) can be classified in women who had 2 or more episodes of pregnancy loss.
The presence of antiphospholipid antibodies (antiphospholipid syndrome - APS) has been associated with placental vascular thrombosis and hence placental infarctions and insufficiency which leads to pregnancy loss. Tests for APS, signaling the presence of the autoimmune disease, have reportedly been positive in approx. 20% of women with early pregnancy losses (RPM). Low-molecular weight heparin (LMWH) and acetyl-salicylic acid (ASA) has been recommended for women with APS and RPM as a prevention treatment. But this approach remains empiric regarding terms and dosage.
Aims: We compared anticoagulant (and partially anti-APS) treatment approaches with LMWH/ASA; LMWH alone and ASA in alone in increased live birth in women with consecutive RPM and APS.
Methods: 44 early pregnant women with RPM/APS were investigated and treated in Minsk Consultative and Diagnostic Center during last 3 years. Serologic criteria defined as at least **one** of the following tests found to be positive on 2 occasions within 3 months: anticardiolipin IgG (> 20 phospholipid units); antiglycoprotein (> 20 units); lupus anticoagulant (LAC) was measured as Russell's viper venom time; activated partial thromboplastin time and prothrombin time. The all cohort was divided to 3 groups: 1) 12 patients were given 75 mg daily of ASA; 2) 20 patients were prescribed LMWH (dalteparin sodium 2500 IU daily, subcutaneously) plus 75 mg of ASA and 3) 12 patients were received dalteparin sodium (2500 IU daily, subcutaneously) only. All medications were prescribed from the 2^{nd} – 3^{d} week of pregnancy till six weeks after the delivery.
Results: In the first group the live birth rate was 10 of 12 (83%); the second group showed 100% of safe births and the third one demonstrated 11 of 12 (91,6%) of successful deliveries. Besides, 2 pregnancies cases from the groups I and II were accompanied by moderate uterine bleeding; both episodes were occurred in the second trimester. The cases demanded no medical intervention; they were uncomplicated and ended by successful delivery. It is interesting to note, that in the groups included ASA the titer of antiphospholipid antibodies has incrementally decreased (20 to 40%) by the end of treatment.
Summary/Conclusion: According the results of our pilot investigation, the "golden standard" of RMC prevention seems to be the combination of ASA and LMWH. But both dalteparin sodium alone and aspirin alone also confers substantial benefit. In some circumstances the ASA treatment looks more attractive due to low price of medication. ASA treatment also seems positively influences on decreasing AA-concentration.

PS1534

LABORATORY CRITERIA FOR THE DIAGNOSTIC RELIABILITY OF TESTS FOR DETECTION OF LUPUS ANTICOAGULANT IN PATIENTS WITH SUSPECTED ANTIPHOSPHOLIPID SYNDROME

V. Krasivska[1,*], O. Stasyshyn[2]

[1]Laboratory of immunocytology and genetics of blood tumors, [2]Surgery and Clinical Transfusiology, State institution "Institute of Blood Pathology and Transfusion Medicine under the NAMS of Ukraine", Lviv, Ukraine

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterized by recurrent arterial or venous thrombosis and/or recurrent pregnancy morbidities in the presence of persistent positive antiphospholipid antibodies (aPL), which includes anticardiolipin antibodies (aCL), anti-b2 glycoprotein I (anti-b2GPI) and lupus anticoagulant (LA). Laboratory criteria of diagnostic reliability of the tests to detect LA haven't been researched profoundly, which is why the research of their informative value is a topical problem.
Aims: To find the most informative coagulologic tests for the detection of LA in patients with suspected APS by identifying diagnostic laboratory eligibility criteria.
Methods: In 233 patients with suspected APS the presence of LA was examined on the basis of a consistent implementation of a three-step test carried out in accordance with the current guidelines. We used clotting time with PL-dependent diluted viper venom time (DVVT), activated partial thromboplastin time APTT with LA -sensitive reagent (APTT) and prothrombin time with diluted to 50 and 500 times thromboplastin ($PT_{1:50}$, $PT_{1:500}$). Also we have calculated sensitivity (Se), specificity (Sp), accuracy (Ac) and likelihood ratio (LR+, LR -) for each of these tests.
Results: APS was diagnosed in 104 (44,6%) patients. Primary APS was detected in 89 (85,6%) patients, 15 (14,4%) were diagnosed with the secondary APS with the systemic lupus erythematosus alongside and other autoimmune diseases. LA was detected in 99 patients, which is 42,5% of the target group. In the group of patients with APS, LA was detected in 95,2% of cases. On the first stage of diagnostics a considerable Sp >75,0% (χ^2>60,0; <0,001) and LR+ (>10,0) of all PL-dependent coagulation tests indicates a high probability of LA presence if clotting time is prolonged. Ac of the first stage tests does not go <75,0% which indicates a fairly big part of true positive and true negative results of the all the examined patients. However, due to low Se (48,1%>56,6%) it's impossible to narrow the quantity of patients with the APC possibility. On the second stage, (mixing studies) we observed the low Se (33,3% - 44,6%) and high Sp (97,7% - 99,2%) of index of circulating anticoagulant (ICA) in all the tests (χ^2>44,74; <0,001). On the third stage (confirmatory tests) Se for LA ratio of all the tests was 61,5% - 74,4% and Sp LA ratio – 95,4% - 98,4% (χ^2 >87,42; <0,001). Ac of all the tests was >87,8%. The probability of LA and APS presence with the increase of LA ratio >1,15 was high (LR+ 16,9-38,1). With moderate possibility LA absence can be stated due to the negative results of all the tests for confirmation: LR - varying from 0,2 to 0,4.
Summary/Conclusion: None of the tests used to diagnose LA showed 100,0% Se and Sp. PL-dependent coagulation tests of the first stage of diagnostics LA have a high diagnostic reliability due to considerable Sp, Ac and LR+ if the coagulation time is prolonged. Low Se of the first stage tests does not give a considerable certainty of anticoagulant absence if the coagulation time is within the norm. On the second stage, with ICA >15,0%, LA can be suspected with high probability, but the low Se does not allow us to confidently differentiate the deficiency of clotting factor from the presence of pathological blood coagulation inhibitors. Statistically, the highest significant diagnostic efficacy was found in the 3-step tests to confirm the PL-dependent nature of the inhibitor, which can be considered sufficiently reliable for detecting LA activity and diagnosing APS.

PS1535

THE COAGULATION SYSTEM FUNCTIONING IN PATIENTS WITH MYELOFIBROSIS

E. Efremova[1,*], O. Matvienko[2], M. Fominykh[1], N. Korsakova[2], N. Silina[2], L. Papayan[2], V. Shuvaev[1], S. Voloshin[1]

[1]Clinical Department, [2]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Pathogenesis of myelofibrosis (MF) is associated with high risk of thromboembolism (arterial and venous). Age older than 60 years, leukocytosis, thrombocytosis and presence of *JAK2V617F* mutation are well-recognized risk factors for thrombotic complications. However, common coagulation tests in patients with MF frequently demonstrate not any or little abnormalities. The Calibrated Automated Thrombography (CAT) as integral hemostasis test could have of value in the coagulation system functional testing in MF patients.
Aims: To investigate functioning of the coagulation system in MF patients using thrombin generation test.
Methods: The study included 13 MF patients (26 – 71 years, median = 40) and 21 healthy controls (20 – 61 years, median = 31,5). There were 11 females and 2 males in the study group. Nine (69%) patients were *JAK2V617F* positive, 4 (31%) were *JAK2V617F* negative (3 were *CALR* positive, 1 had mutation in *MPL*). Thrombin generation was assessed by calibrated automated thrombinography (CAT) according to Hemker *et al.* Assessments were conducted in platelet poor plasma (PPP) with or without presence of thrombomodulin (PPP reagent +/– TM). The following parameters were evaluated: endogenous thrombin potential (ETP, nM*min), peak thrombin (Peak, nM). Sensitivity ETP and Peak for TM were calculated as percent of decreasing of these parameters after adding to assay of TM (S ETP,% and S Peak,% respectively). STATISTICA 6.0 package was used in data analysis. Results were presented as median (Me) with 95% confidence intervals (CI), $p<0.05$ was considered statistically significant for difference interpretation.
Results: Table 1.
Summary/Conclusion: ETP and Peak were lower in MF patients comparing to control group. However, MF patients have considerable decrease sensi-

tivity for TM, which indicates dysfunction of anticoagulant protein C system. The disability in anticoagulant protein C system can lead to offset hemostatic balance and hypercoagulability which serve as underlying conditions for thrombotic complications.

Table 1.

Parameters of CAT	Patients (n=13)	Controls (n=21)
ETP, nM*min	1781.26 (808.47-1759.19)*	1725.00 (1210.5-2179.5)
S ETP (%)	43 (3.67-67.31)*	51.53 (22.49-65.49)
Peak, nM	183.47 (103.37-292.58)*	288.61 (193.24-376.7)
S Peak, %	20.0 (0.26-46.99)*	35.49 (14.56-53.78)

*p<0,05 for difference between patients and controls.

PS1536

PLATELET MAPPING BY THROMBOELASTOGRAPHY- ASSESSMENT OF PLATELET INHIBITION SECONDARY TO ANTIPLATELET THERAPY AFTER PCI

D. De[1,*], S.S. Datta[2], N. Afroz[2]

[1]Dept of Hematology, [2]the Mission Hospital, Kolkata, India

Background: Platelet mapping by TEG is a modification of conventional TEG which measures platelet functions. Dual antiplatelet therapy are the gold standard to attenuate platelet function during PCI. However, it has been demonstrated that nearly 20% of patients undergoing PCI will experience recurrent thrombotic events.
Aims: To assess the extent of resistance to clopidogrel, prasugrel, and ticagrelor in a group of patients who underwent PCI due to coronary artery disease by platelet mapping by thrombelastography.

Results

	Clopidogrel (75 mg OD)	Prasugrel (10mg OD)	Ticagrelor (90mg BD)
Total Patient Tested	18	15	23
Resistant (<50%)	3	3	0
% of Resistance	16.67	20	0
Mean Platelet inhibition	69.228	64.113	82.257
SD	24.054	24.951	14.030
Std Error of Means	5.670	6.442	2.925
P value of means	0.0360	0.0068	-

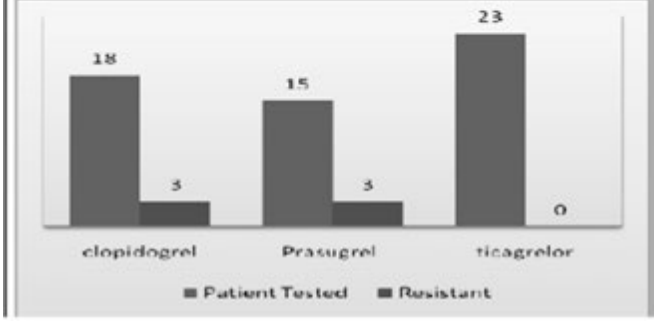

Figure 1.

Methods: This is a prospective, comparative, observational single-center cohort study. Included 56 patients who underwent a PCI from June 2016 to June2017. All patients were on aspirin and on any of the three drugs, namely, clopidogrel, prasugrel and ticagrelor, The average percentage platelet inhibition was assessed. Sensitivity and resistance to the specific drug was defined as >50% and <50% of mean platelet inhibition, respectively. The percentage of platelet aggregation to agonist can be calculated by: [(MA ADP/AA - MA Fibrin)/ (MA Thrombin – MA Fibrin)×100].
Results: The study found that the mean percentage platelet inhibition was significantly higher in patients with ticagrelor as compared with clopidogrel and with prasugrel (p value of 0.0360 and 0.0068, respectively) (Figure 1).
Summary/Conclusion: Platelet mapping by Thrombelastography can be successfully implemented in the patients undergoing PCI to assess its reliability as a monitoring tool for analyzing the response to antiplatelet therapy. Use of ticagrelor as dual therapy along with aspirin in patients with coronary artery disease (CAD) and undergoing PCI was associated with a significantly higher mean percentage platelet inhibition, higher sensitivity, and lower resistance as compared with the usage of clopidogrel or prasugrel.

Transfusion medicine

PS1537

IMMATURE PLATELET FRACTION: A USEFUL MARKER FOR IDENTIFYING THE CAUSE OF THROMBOCYTOPENIA AND PREDICTING PLATELET RECOVERY

E. Lee[1,*], K. Jeon[1], M. Kim[1], J. Lee[1], H.-S. Kim[1], H.J. Kang[1], Y.K. Lee[1]

[1]Laboratory medicine, Hallym Sacred Heart Hospital, Anyang, Korea, Republic Of

Background: We evaluated the discriminatory power of the immature platelet fraction (IPF%) along with plateletcrit (PCT), platelet distribution width (PDW), mean platelet volume (MPV), absolute immature platelet number (IPF#), and platlet-large cell ratio (P-LCR).
Aims: Aims of this study were to evalute the peformance of IPF% in differentiating hyperdestructive/consumptive thrombocytopenia from hypoproductive thrombocytopenia, and to evaluate its potential use as a predictive marker for platelet recovery.
Methods: The study included 105 healthy individuals (the control group), 31 patients with hyperdestructive/consumptive thrombocytopenia (14 with immune thrombocytopenic purpura [ITP] and 17 with liver cirrhosis [LC]), and 34 patients with hypoproductive thrombocytopenia (4 with aplastic anemia [AA] and 30 with cancer who were undergoing chemotherapy) by using a Sysmex XN-3000 hematology analyzer equipped with platelet specific channel (platelet-F).
Results: All the parameters analyzed in this study were significantly different in the 2 thromobocytopenia groups, but not always between the control group and the hypoproductive thrombocytopenia group. Compared to the control group, the hyperdestructive/consumptive thrombocytopenia group showed a 32.1% increase in the PDW, a 20.0% increase in the MPV, a 190.5% increase in the IPF%, a 25.6% decrease in the IPF#, a 45.7% increase in the P-LCR. Hypoproductive thrombocytopenia group showed a 6.1% decrease in PDW, a 6.5% decrease in MPV, a 9.5% decrease in the IPF%, a 69.8% decrease in the IPF# and a 4.9% increase in the P-LCR. In the hyperdestructive/consumptive group, the IPF% was 4.7%, 6.2%, and 11.4% in patients with platelet counts >90.0×10^3/μL, 40.0–90.0×10^3/μL and <40.0×10^3/μL, respectively (p=0.010). However, this phenomenon was not observed in the hypoproductive thrombocytopenia group. In a ROC analyses, the AUC was highest for IPF% (0.938), indicating that this parameter showed the best discriminatory ability between the two groups, followed by PDW (0.885), P-LCR (0.859), IPF# (0.827), and MPV (0.824) (all P-values <0.001). The IPF% showed an inverse relationship was observed between the platelet count and IPF%. The platelets increased to over 40.0×10^3/μL in 3–4 days after the IPF% decreased from its highest value in the 2 ITP patients with the baseline platelet counts under 10.0×10^3/μL. While thrombocytopenia occurred at each cycle of chemotherapy, an increase in the IPF% beyond the median value of IPF% in the control group (2.1%) coincided with a platelet count increase over 130.0×10^3/μL) in a median 5.5 days in 4 cancer patients under chemotherapy. The other patients (patient 11, 12 and 13) were excluded from the analysis because their platelet recovery seemed more dependent on platelet transfusion than on bone marrow thrombopoiesis during the study period.
Summary/Conclusion: We demonstrated for the first time that IPF% as reported by an XN-3000 instrument is an excellent marker for distinguishing hyperdestructive/consumptive thrombocytopenia from hypoproductive thrombocytopenia. Furthermore, by reflecting the BM's thrombopoietic activity, IPF% as reported by an XN-3000 is a robust and reliable marker for the prediction of platelet recovery in patients with ITP and those with cancer who are undergoing chemotherapy. This can assist in providing future therapy guidance and preventing unnecessary transfusions.

PS1538

PLATELETPHERESIS-ASSOCIATED LYMPHOPENIA IN FREQUENT PLATELET DONORS

J. Gansner[1,*], M. Rahmani[2], B. Fortin[1], I. Brimah[3], M. Ellis[2], R. Smeland-Wagman[2], D. Crown[2], J. Schenkel[2], N. Balan[1], R. Yefidoff-Freedman[1], S. Sloan[24], N. Berliner[1], N. Issa[1], L. Baden[1], D. Longo[1], D. Rao[1], D. Wesemann[1], D. Neuberg[5], R. Kaufman[2]

[1]Medicine, [2]Pathology, [3]Center for Clinical Investigation, Brigham and Women's Hospital, [4]Laboratory Medicine, Boston Children's Hospital, [5]Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston, United States

Background: Platelet donors undergo plateletpheresis to collect platelet units that can be transfused to patients who are bleeding or at risk of bleeding. During plateletpheresis with the Trima Accel instrument, leukocytes are diverted into a leukoreduction system chamber, yielding leukoreduced platelet units. Based on an index case seen in our hematology clinic, we hypothesized that frequent plateletpheresis involving a leukoreduction system chamber would result in donor lymphopenia.
Aims: We investigated the blood counts (including CD4+ and CD8+ T-lymphocyte counts) of apheresis platelet donors who had undergone different numbers of plateletpheresis collections.
Methods: We conducted a prospective, observational study of platelet donors at one hospital-based donor center. A total of 60 adult donors were recruited, 20 in each of 3 pre-specified groups. These groups were defined by the number of successful plateletpheresis sessions in the prior 365 days, including the date of study participation: ≤2 sessions, 3-19 sessions, and ≥20 sessions. Subjects were excluded from participation if they had donated platelets at any other site in the past. All plateletpheresis procedures were performed using the Trima Accel instrument. Whole blood specimens were obtained before plateletpheresis, from the leukoreduction system chambers, and after plateletpheresis.
Results: The baseline white blood cell count, hematocrit, and platelet count were not significantly different among the three groups. Donors in the ≥20 sessions group exhibited reduced absolute lymphocyte counts compared to donors in the ≤2 sessions group, with striking reductions in both CD4+ and CD8+ T-lymphocyte counts. Six of 20 donors (30%) in the ≥20 sessions group had CD4+ T-lymphocyte counts below 200 cells/μL, compared with 2 of 20 donors (10%) in the 3-19 sessions group and 0 of 20 donors (0%) in the ≤2 sessions group, p=0.0189 (Image). CD8+ lymphocyte counts were below the reference range (<125 cells/μL) in 11 of 20 donors (55%) in the ≥20 sessions group, 4 of 20 donors (20%) in the 3-19 sessions group, and 0 of 20 donors (0%) in the ≤2 sessions group, p=0.0003. By examining donor history questionnaires, we confirmed the good health of all platelet donors, who are extensively screened for multiple pathogens; all are HIV negative. To investigate the mechanism of plateletpheresis-associated CD4+ and CD8+ T-cell lymphopenia in frequent platelet donors, we calculated the efficiency of blood cell extraction by the leukoreduction system chamber. Consistent with independent reports, these chambers contained high numbers of lymphocytes. The extraction efficiency of the chambers was ~15-20% for lymphocytes and monocytes, ~10-15% for basophils, and <1% for neutrophils and eosinophils. There was no clear selectivity in extraction efficiency with regards to lymphocyte subset (Figure 1).

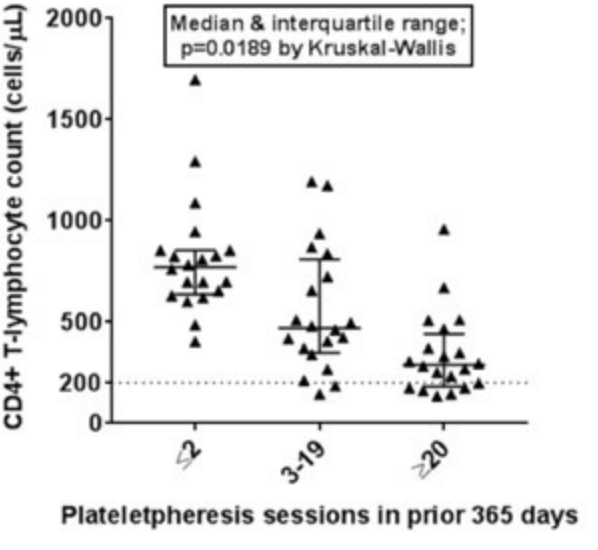

Figure 1.

Summary/Conclusion: Frequent plateletpheresis (≥20 plateletpheresis sessions in the prior 365-day period) involving a leukoreduction system chamber is associated with a surprising degree of lymphopenia in healthy platelet donors. We suspect that this may be due to repeated extraction of these cells by the chamber. A CD4+ T-lymphocyte count below 200 cells/μL has been used to define advanced immunodeficiency associated with HIV infec-

tion; however, our frequent platelet donors appear well. There is no evidence that the changes in cell counts are associated with increased risks. We are performing more extensive lymphocyte immunophenotyping as well as T-cell receptor repertoire sequencing to better characterize the immune systems of frequent platelet donors.

INTRACRANIAL HEMORRHAGE IN LEUKEMIA PATIENTS: PRELIMINARY RESULTS OF AN ONGOING NESTED CASE CONTROL STUDY

L.L. Cornelissen[1,2,*], A. Kreuger[1,3], R. Middelburg[1,3], E. Beckers[4], P. von dem Borne[5], J. Kuball[6], K. de Vooght[7], J. Zwaginga[1,2], J. Kerkhoffs[1,8], J. van der Bom[1,9]

[1]Center for Clinical Transfusion Research, Sanquin Research, [2]Department of Immunohematology and Blood Transfusion, Leiden University Medical Center, [3]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Leiden, [4]Department of Hematology, Maastricht University Medical Center, Maastricht, [5]Department of Hematology, Leiden University Medical Center, Leiden, [6]Department of Hematology, [7]Department of Clinical Chemistry and Haematology, University Medical Center Utrecht, Utrecht, [8]Department of Hematology, Haga Hospital, Den Haag, [9]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

Background: Intracranial hemorrhage is one of the most serious bleeding complications in thrombocytopenic hemato-oncology patients. To prevent such bleeding complications patients frequently receive prophylactic platelet transfusions based on the platelet count. However, the evidence for low platelet count as an independent risk factor is inconclusive. Other clinical risk factors are thought to also modify the bleeding risk.
Aims: To describe the association of platelet counts, transfusions and clinical risk factors like age, sex, infection and medication in the previous seven days with the risk of intracranial hemorrhage in patients with acute leukemia.
Methods: Nested case control study in a cohort of leukemia patients in four hospitals. Cases with intracranial hemorrhage were identified with a regression model previously designed to identify patients with major hemorrhages. Controls were matched on diagnosis, therapy and time. Cases were excluded in case of inability to identify suitable controls, uncertain date of intracranial hemorrhage or irretrievability of clinical data. Clinical risk factors were recorded from medical records for seven days preceding the bleeding for cases, or for the corresponding index period for controls. Univariate conditional logistic regression was performed to explore the association of bleeding with platelet count and potential risk factors.
Results: We identified 39 cases in four hospitals of which 25 were excluded for one of the exclusion criteria. Fourteen cases and 44 controls were included in the case control analysis. Most patients had acute myeloid leukemia (63.8%). 79.3% of the cases received remission induction for a new or relapsed leukemia, 3.5% received consolidation therapy, 3.5% allogeneic stem cell transplantation and 13.8% were admitted for disease or treatment related complications. Having a morning platelet count $<10x10^9$ was not associated with increased bleeding risk (OR 0.88, CI 0.10 to 8.13). Age was associated with an increased bleeding risk (OR 1.1/year, CI 1.01 to 1.18). Sex showed no relevant association (women: OR 1.21, CI 0.39 to 3.78). Compared to none, receiving one or two platelet transfusions in one week was associated with intracranial hemorrhage (OR 4.3, CI 0.70 to 26.28). For three or more platelet transfusions this risk increased (OR 6.4, CI 1.07 to 37.65. p-value for trend=0.044). Furthermore, presence of an infection proven by any positive culture or positive polymerase chain reaction (OR 2.58, CI 0.65 to 10.30) and usage of antihypertensive medication (OR 12.2, CI 1.36 to 110.36) were associated with an increased risk of intracranial hemorrhage.
Summary/Conclusion: Age, usage of antihypertensive medication and the presence of a culture or polymerase chain reaction proven infection were associated with an increased risk of intracranial hemorrhage. Also, the need for platelet transfusion was associated with an increased risk of intracranial hemorrhage. Although this does not imply causality, these conclusions could be relevant in platelet transfusion decision making.

PS1540

QUALITY CONTROL IN CRYOPRESERVED POOLED PLATELETS: 9-YEAR EXPERIENCE IN A TRANSFUSION CENTRE

A.M. Hernández Vidaña[1], J.A. García Bautista[1], P. Romero Garcia[2,*], C. Delgado Calvo-Flores[1], M.A. García Ruiz[3], M. Jurado Chacón[3], S. Oyonarte Gómez[1]

[1]Centro Regional de Transfusión Sanguínea, Granada, [2]UCI, Hospital de Santa Barbara, Soria, [3]Servicio de Hematología y Hemoterapia, Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: The Centre for Blood Transfusion of Granada, Spain, offers as a part of its service portfolio, the production, storage and distribution of cryopreserved pooled paletelet concentrates for transfusional use. This procedure was implemented in 2009 to respond to potential situations of platelet shortage, as well as to supply platelet concentrates to hospital centers whose characteristics do not allow them to have a permanent stock of fresh platelets. Its main drawbacks are the loss of *in vivo* hemostatic capacity, and the cost and complexity of the manufacturing process.
Aims: Validate the efficacy of platelet cryopreservation to ensure transfusion requirements in any emergency in hospitals.
Methods: The production method used in our center is based on 5-unit pooled leucodepleted platelets, no older than 24 hours, which undergo successive steps of resuspension in citrate and mixing with cryopreservant solution composed of albumin and dimethylsulfoxide, which is finally removed by centrifugation before storage at -80°C. Pools with a platelet count above $1{,}000\times10^3/\mu l$ are selected, and the final volume is adjusted to 200 ml. This product can be issued frozen at -80 ° C for storage, or thawed and resuspended for use within 6 hours. We present the evolution of the production data in our center and the quality control parameters of cryopreserved pooled platelet units from 2009 to 2017. Annual and weighted average volume data, platelet recovery (calculated from platelet initial and final counts) and count of residual leukocytes are analyzed. In addition, a sterility control was performed prior to cryopreservation.
Results: In the reviewed period we have produced a total of 1,629 cryopreserved pooled platelet units. All of them have been quality-controlled before use, as described above, which allows us to verify compliance with standards regarding platelet recovery (>40% of baseline count) and residual leukocyte content ($<1x10^6$/unit).
Summary/Conclusion: The production and issuing of of cryopreserved pooled platelet units maintain an ascending line, which reflects their usefulness for Transfusion Services and the logistic advantages that it offers. Our experience throughout these 9 years in the elaboration and distribution of cryopreserved platelets has been very satisfactory, allowing the following advantages: 1) hospitals with a long distance to the Transfusion Center, where platelet transfusions are not usual, have seen a decline in the needs for urgent transport and expiration rate of fresh platelet pools, while allowing them to have a permanent stock of transfusion-ready platelets. 2) It has allowed to better adjust platelet unit stocks in all the Transfusion Services. 3) Ensuring that our center maintains a constant platelet safety stock on periods like holidays when it is difficult to guarantee a large enough number of donations. 4) Maintaining the availability of trnsfusion-ready platelets when facing unexpected peaks in consumption. Regarding production, we have achieved average values well above the standards in terms of platelet recovery (72.4%), platelet content ($3.15\ x10^{11}$ / unit), and residual leukocytes of $0.09x10^6$/unit. We must also note that these good results have remained constant over these years, despite the increase in production.

PS1541

BACTERIAL CONTAMINANTS AND BIOFILMS EFFECT PLATELET ACTIVATION AND FUNCTION: IMPLICATIONS IN PLATELET TRANSFUSIONS

J. Wilson-Nieuwenhuis[1,*], K. Whitehead[1], N. Dempsey-Hibbert[1]

[1]School of Healthcare Science, Manchester Metropolitan University, Manchester, United Kingdom

Background: Every year in the UK, approximately 250,000 platelet units are transfused and demand is increasing year on year. Due to their storage requirements pre-transfusion, platelet concentrates (PCs) are highly susceptible to bacterial growth if they have been contaminated during the donation or manufacturing process. Bacterial cells living freely within the blood unit may become attached to the surface, and form a biofilm. Biofilm formation can lead to increased virulence, and development of anti-microbial resistance. Much of the focus on bacterial contamination of PCs is on preventing the infusion of these bacteria in to the transfusion recipient, as transfusion-associated sepsis can cause major morbidity and mortality. And yet, identification of contaminated units within the blood bank still poses a problem and contaminated units are often released for transfusion, particularly if the bacteria have formed a biofilm. However, the effects of low levels of planktonic bacteria and biofilm formation on platelet activation and function has so far, been relatively understudied.
Aims: This work aimed to determine the effects of planktonic bacteria and bacterial biofilms on platelet activation and function in response to a com-

mon platelet agonist, with the purpose of establishing whether the efficacy of platelets within these contaminated units is also compromised.
Methods: Platelet rich plasma (PRP) was obtained by centrifugation of whole blood obtained from healthy participants after ethical approval and informed consent. PRP was incubated with either *Staphylococcus epidermidis* or *Serratia marcescens* (two species commonly implicated in platelet unit contamination) in either planktonic or biofilm forms prior to stimulation with ADP (10μM) and analysis of alpha granule secretion (CD62P expression) and GPIIbIIIa activation (PAC1 expression). Further, ADP-stimulated aggregation was assessed using light transmission aggregometry (LTA) after these treatments. Finally, RANTES release by platelets was determined via cytometric bead array.
Results: Platelet aggregation following contamination with planktonic cells showed no significant differences when compared with aggregation of uncontaminated platelets. However, incubation with biofilms (grown for 5 or 7 days prior to culture with platelets) was shown to significantly inhibit platelet aggregation ($p<0.05$). However, no significant changes in CD62P or PAC1 expression were determined following culture with planktonic bacteria or biofilms. RANTES release by platelets (ADP-stimulated or not) was significantly increased when platelets were incubated with a 7-day biofilm of either bacterial species, highlighting the platelets' role in host-defence.
Summary/Conclusion: The study demonstrates the inhibitory effects of low concentrations of commensal skin microflora on platelet activation and function, and highlights the need for strategies to prevent biofilm formation on platelet bag surfaces.

PS1542

ALLOIMMUNIZATION TO D AND NON-D RHESUS ANTIGENS INDUCED BY PLATELET TRANSFUSIONS

M. Daskalakis[1,*], J. Reckhaus[1], M. Jutzi[2], S. Fontana[2], U. Bacher[1], M. Vogt[1], B. Mansouri Taleghani[1]

[1]University Hospital of Hematology and Hematologic Central Laboratory, Inselspital, University of Bern, [2]Interregional Blood Transfusion, Swiss Red Cross, Bern, Switzerland

Background: Platelet concentrates (PC) contain residual contaminating red blood cells (RBC), being higher in pooled buffy coat PCs (BC-PC) than in apheresis units (AP-PC). Data about PC-induced alloimmunization against non-D Rhesus (Rh) antigens are limited.
Aims: Implementation of a systematic prospective assessment of every single newly identified Rhesus alloantibody for the putative triggering blood product transfused. With this hemovigilance-induced quality assurance measure we aimed to identify possible further cases in order to delineate the frequency, the antibody specificities, and the circumstances that may be associated with this phenomenon.
Methods: For all newly detected Rhesus D and non-D allo-antibodies between 08/2015 and 09/2017 we prospectively evaluated if they were triggered through PC by analysing for incompatible RBC and/or PC transfusions by compiling the patient s data (age, gender, AB0 blood group and Rhesus phenotype, main diagnoses, immunosuppressive drugs, transfusion history, and date of alloantibody detection) as well as transfusion history (included every RBC and PC unit). Recorded data of donors/PC/transfusions included: gender, age, AB0 blood group and Rhesus phenotype, AP-PC or BC-PC, date of transfusion. Routine quality control (QC) for residual RBC count was performed for 10 AP-PC and 10 BP-PC every month. Geometric mean and range was calculated including all QC RBC- counts for AP-PC and BC-PC from 01/2016 through 12/2016. Based on previous publications, we considered newly detected antibodies following a Rhesus incompatible PC transfusion until day 27 as secondary immune response (booster effect) and those found on day 28 or later as a primary immune response against Rh antigens.
Results: We identified 13 newly detectable Rh-antibodies through incompatible PCs in 11 patients: 6x anti-D, 4x anti-E, 2x anti-c, 1x anti-f. The patients received a total of 156 PC (83 BC-PC; 73 AP-PC): five patients received incompatible BC-PC only, one patient received incompatible AP-PC only, 5 patients received incompatible BC-PC and AP-PC. Quality control showed a mean (range) of 0.304 (0.152–1.662) and 0.014 (0.003–0.080)x10^9 RBC/L for BC-PC and AP-PC, respectively. Ten of the 11 patients received RBC-transfusions, all of them being antigen-negative for the alloantibodies identified.
Summary/Conclusion: PC transfusions may not only induce Rh D alloimmunization, but also immunization against further Rh antigens such as c, E, and f. The risk is higher for BC-PC than AP-PC. The results may have impact on future recommendations of PC transfusion with respect to Rh compatibility and upper limits of RBC contamination.

PS1543

MASSIVE TRANSFUSION PROTOCOLS - FRIEND OR FOE ?

S. Ching[1], G. Chen[1], M. L. Tung[1,2,*]

[1]Laboratory Medicine, Ng Teng Fong General Hospital, [2]Haematology-Oncology, National University Cancer Institute, National University Health System, Singapore, Singapore, Singapore

Background: Massive Transfusion Protocols (MTPs) are increasingly adopted by hospitals as the evidence shows that it is beneficial in bleeding patients. However, inappropriate or overactivation of MTPs can result in increased blood wastages.
Aims: The aim of this study was to review the effects of the implementation of a MTP in Ng Teng Fong General Hospital (NTFGH) and its impact on blood product wastage.
Methods: A retrospective review of all the MTPs activated in NTFGH from July 2016 to June 2017 was performed by the medical technologist from the transfusion laboratory. 3 categories of MTP was defined as per the hospital's protocol with the following blood product ratio: a) Pack 1: 4 units red blood cell (RBC), 4 units of platelet (PLT), 4 units of fresh frozen plasma (FFP) and tranexamic acid 1, b) Pack 2: 4 units RBC, 4 units PLT, 4 units FFP and 10 units cryoprecipitate (CRYO); c) Pack 3: 4 units RBC, 4 units PLT and 4 units FFP. The decision to activate MTP is made by the clinician based on impending or actual haemorhagic shock in a bleeding patient. The total number of blood products ordered, returned and wasted were recorded monthly.
Results: A total of 22 patients received MTPs during this period with 236 blood products ordered. Of these products ordered, 74 were returned and were made up of 28 units of RBC, 7 units of PLT and 39 units of FFP. FFP contributed to 97.1% of the blood products wasted. 33.3% of all the MTPs did not result in any blood products being returned or wasted (Table 1). Figure 1 shows that a total of 81 units of blood products were wasted during this period. 43.2% of those units were attributed to MTPs.

Table 1.

Month/ Year	MTP	Total Products Ordered	RBC	FFP	PLT	CRYO	Total Products Returned	RBC	FFP	PLT	CRYO	Total Products Wasted	RBC	FFP	PLT	CRYO
Jul-16	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Total	27	236	101	102	25	8	74	28	39	7	0	35	1	34	0	0

Figure 1.

Summary/Conclusion: Although MTPs are useful in bleeding patients, our data shows that it is a major contributor to blood product wastages, especially FFP. More research is required to help guide clinicians in the appropriate activation of MTPs.

PS1544

PLATELET-DERIVED MICROPARTICLES; THE EXPRESSION PROPERTIES AND POTENSIAL AS A SUBSTITUTE FOR PLATELETS

S. Azadpour[1,*], F. Yari[2]

[1]Hematology, Abadan school of medical sciences , Abadan, Iran., Abadan, [2]Blood Transfusion Research Center, High Institute for Research and Education in Transfusion Medicine, Tehran, Iran, Islamic Republic Of

Background: Since the use of platelet products is limited due to the side effects of platelet transfusions, viral and bacterial contamination and short expiration date, many efforts have been made to create alternatives for platelets in transfusion medicine. one of the responses of activated platelets to certain stimuli is the shedding of microparticles *in vivo* and definitely *in vitro* upon aging under storage. Elevated MPs in various diseases indicate their diagnostic importance, particularly in vascular pathologies. It has been revealed that these microparticles had hemostatic activity. These activities originate from the surface markers of platelet-derived microparticles (PDM).
Aims: The aim of this study was to survey the size and expression of surface glycoproteins of PDM in platelet concentrate to characterize more these micropaticles.
Methods: 30 units of platele concentrate (PC) were prepared from Iranian Blood Transfusion Organization. PDM were isolated using centrifugation from PC during 7 days storage. The size of PDM were determined using a particle-sizing instrument. Besides, We determined MP adhesion capacity to annexin-V due their PS contents by using ELISA method. Additionally, the expression of gpIb and IIb/IIIa on the PDM during the storage time were also studied using flow cytometry method. For this purpose, FITC-conjugated mouse antiCD41 (HIP8), mouse anti-human CD42b, FITC-conjugated goat anti-mouse IgG (Fab') 2 were used and the analysis was carried out using flow cytometry technique. For all the experiments, nonspecific binding was analyzed as it was explained. for studying the vWF binding properties of MPs, MPs was added to the tubes containing human vWF in the presence of ristocetin as a modulator. After, the MPs was washed and incubated for 30 minutes with rabbit anti-human vWF. The MPs was washed again and incubated with fluorescein isothiocyanate–conjugated goat anti-rabbit IgG. To be sure of the specificity of results, nonspecific antibody background binding was determined with the appropriately labeled isotypic control immunoglobulin IgG. Finally, the results of the experiment were surveyed using flow cytometry technique.
Results: The size distribution of platelet-derived microparticles (PDM) was determined in the range of 146 to 797 nm (Z-Average=782 nm). Furthermore, the expression of gpIIb/IIIa and gpIba molecules was demonstrated on the surface of platelet-derived microparticles (PDM). Platelet-derived microparticles (PDM) as platelet had adhesion capacity to annexin-V due their phosphatidylserine (PS) contents. In addition, the data showed that MPs could bind to vWF at the days 2, 4 and 7 of storage. The difference was significant between the days 2 and 7 for the expression of gpIIb/IIIa and gpIba on the microparticles (P-value<0.05).
Summary/Conclusion: This study could imply the expression of the same surface markers of platelets on the platelet-derived microparticles. These markers could explain the hemostatic activities of these microparticles. The results can imply the potential capacity of the platelet-derived microparticles as a platelet substitute product. Inspired by this, It is hoped to be able to use of the nano techniques to design the platelet-derived nanomicroparticles that exhibit platelet-like coagulation functions. Additionally, the reduction of surface glycoproteins was revealed on the PDM during 7 days of storage.

Klinik [3], LMU, München, [4]Internal Medicine I, Köln University, Köln, Germany, [5]Clinica Oncoematologica S.C. Ematologia, Arcispedale S. Maria Nuova, Reggio Emilia, Italy, [6]Heidelberg University, Heidelberg, [7]Oncology and Hematology, UKE Eppendorf, Hamburg, [8]Klinikum Chemnitz, Chemnitz, [9]University Goettingen, Goettingen, [10]Klinikum Oldenburg, Oldenburg, [11]University Mannheim, Mannheim, [12]TU München, München, [13]Clinic for Radiotherapy, Saarland University Medical School, Homburg, [14]University Muenster, Muenster, [15]Westpfalz-Klinikum, Kaiserslautern, Germany

Background: The role of RT to B and E for young patients with good-prognosis DLBCL is ill-defined.
Aims: *The aim of the study was to determine the role of radiotherapy to bulky and extranodal disease and compare the efficacy of R-CHOP-14 and R-CHOP-21 in young DLBCL patients.*
Methods: 18-60 year-old patients (aaIPI=0 with B [≥7.5 cm], aaIPI 1) qualifying for radiotherapy to B or E were randomized to 6xR-CHOP-14 or 6x-R-CHOP-21 followed by RT (39.6 Gy) to B and E sites or observation in a 2x2 factorial design. Primary endpoint was event-free survival.
Results: A planned interim analysis of the first 285 patients had revealed a significantly better EFS of patients assigned to RT (p=0.004) resulting in the pre-defined closing of the non-RT arms. 305 pts (R-CHOP-21: 155; R-CHOP-14: 150) assigned to RT and 162 (R-CHOP-21: 81, R-CHOP-14: 81) assigned to observation were evaluable for this final analysis. There were no relevant differences in protocol adherence and toxicity between the two chemotherapy regimens. EFS, PFS and OS after R-CHOP-14 and R-CHOP-21 were not different. After 66 months median observation 3-year EFS was worse in pts not assigned to RT (68% *vs* 84%; p=0.001), due to a higher rate of PR (11% *vs* 2%) triggering additional treatment (mostly RT) as an EFS event. 3-year PFS of pts assigned to RT was not significantly better (89% *vs* 81%; p=0.221) and 3-year OS (93% *vs* 93%, p=0.506) was not different, which was confirmed in a multivariate analysis adjusting for elevated LDH, stage III/IV, B and E involvement (HR_{EFS}=0.5 [95%CI: 0.4-0.8], p=0.001; HR_{PFS}=0.7 [0.5-11], p=0.174; HR_{OS}=1.2 [0.6-2.2], p=0.674). Results were not different when the analysis was restricted to patients with bulky disease only.
Summary/Conclusion: There were no differences in outcome between R-CHOP-14 and R-CHOP-21. Patients assigned to observation had a worse EFS because of more events largely due to a higher PR rate triggering additional treatment with no differences in PFS and OS. These results highlight the difficulties in interpreting residual masses in DLBCL without a PET which has been shown to identify (elderly) patients with B who can be spared from radiotherapy without compromising their outcome [Pfreundschuh et al., ASCO 2017, #7506]. S*upported by Deutsche Krebshilfe, Amgen and Roche*

S1546

SURVIVAL OF VERY ELDERLY PATIENTS WITH DLBCL ACCORDING TO TREATMENT INTENSITY IN THE RITUXIMAB ERA: A SWEDISH LYMPHOMA REGISTRY STUDY

K. Sonnevi[1,*], M. Christopher[2], H.R. Junlén[2], B.E. Wahlin[2]

[1]Hematology, [2]Medicine, Karolinska Institute, Stockholm, Sweden

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive lymphoma and its incidence rises with increasing age. Several studies have confirmed that rituximab combined with chemotherapy is the best treatment option, but few randomized trials included patients over 80 years of age. Anthracycline-based treatment in combination with rituximab offers a potential cure but comes with substantial risk of adverse events, especially in elderly patients. The treating doctor always has to consider the individual patient's co-morbidity and risk of complications.
Aims: To use data from the Swedish Lymphoma Registry to compare survival in DLBCL in the very elderly according to treatment intensity.
Methods: The Swedish Lymphoma Registry provided data on diagnosis, clinical factors and therapy and survival status on all patients ≥80 years diagnosed with DLBCL in Sweden 2007 through 2012. To reduce the selection bias that is inherent in retrospective analyses of different therapeutic algorithms, we also compared treatment differences in the Healthcare Regions. We investigated whether regional policy differences correlated with survival in all patients within the Regions (regardless of actual treatment given) using Cox proportional hazards model.
Results: In total 799 patients ≥80 years were identified from the SLR; 47% were male and 53% female. At diagnosis, age-adjusted international prognostic index (aaIPI) ≥2 was seen in 49% and bulky disease in 20%. Patients treated with anthracycline-based treatment with curative intention (R-CHOP-21, R-CHOP-14, R-CHOEP) showed significantly better survival with a hazard ratio (HR) of 2.5 (95% confidence interval [CI], 2.2-3.0) compared with patients treated with palliative regimens or no chemotherapy at all. In the Regional analysis, two Regions treated a relatively large proportion of their elderly patients with curative intent (58% in total) whereas three Regions showed a lower fraction (43% in total) and one Region deviated with a considerably low percentage (33%). These treatment differences were highly significant (p<0.001). The overall survival was also significantly better in the more intensive Regions compared with the less intensive and the least intensive Region, HR 1.3 (95% CI 1.1-1.6) and HR 1.5 (95% CI 1.2-1.9).
Summary/Conclusion: In this large, nationwide, population-based study we show that anthracycline-based treatment with curative intention is associated with improved survival also in the very elderly patients over 80 years of age. Furthermore, we can show that the proportion of patients treated with curative intention vary between different healthcare Regions in Sweden suggesting different routines when it comes to treating the very elderly. We used the Regional differences to validate our results by showing that Regions with more intensive treatment traditions have better overall survival. This analysis can be seen as a geographic randomization that is unaffected by response to therapy and co-morbidity since the intensity of treatment is significantly differs merely on the basis of region. We conclude that also patients over the age of 80 years benefit from anthracycline-based treatment with curative intention.

S1547

IMPACT OF CONCURRENT FOLLICULAR LYMPHOMA OR OTHER LOW-GRADE B-CELL LYMPHOMA ON THE CLINICAL OUTCOME OF DIFFUSE LARGE B-CELL LYMPHOMA

Y. Wang[1,*], B. Link[2], M. Maurer[1], C. Allmer[1], T. Witzig[1], T. Habermann[1], S. Ansell[1], R. King[1], A. Feldman[1], S. Slager[1], J. Cerhan[1], G. Nowakowski[1]

[1]Mayo Clinic, Rochester, [2]University of Iowa, Iowa, United States

Background: A significant percentage of patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL) have concurrent follicular lymphoma (FL) or other low-grade B-cell lymphoma in tissue and/or bone marrow biopsies. Clinically these patients are usually treated in the same way as those with pure *de novo* DLBCL. However, it is unclear whether they also have identical outcomes compared with *de novo* DLBCL patients. As a result, whether to include these patients in clinical trials of DLBCL remains controversial.
Aims: To compare the clinical characteristics and outcomes of patients with *de novo* DLBCL, concurrent DLBCL and FL (DLBCL+FL), or concurrent DLBCL and other low-grade B-cell lymphoma (DLBCL+LG).
Methods: 1448 patients with newly diagnosed DLBCL from March 2002 to April 2015 were included in this study. Patients were enrolled in the Molecular Epidemiology Resource (MER) of the University of Iowa/Mayo Clinic lymphoma Specialized Program of Research Excellence (SPORE), treated with standard immunochemotherapy and followed prospectively. Event-free survival (EFS) was defined as time from diagnosis to progression or relapse, unplanned re-treatment after initial immunochemotherapy, or death from any cause. Overall survival (OS) was defined as time from diagnosis to death from any cause. Categorical data were analyzed by Chi-square test, and time-to-event data were analyzed using Kaplan-Meier method. Statistical analysis was done in SPSS (V22).
Results: Among the 1448 patients, 1262 (87.2%) had *de novo* DLBCL, 113 (7.8%) had DLBCL+FL, and 73 (5.0%) had DLBCL+LG. In the DLBCL+FL

cohort, 87 (77%) patients had DLBCL and FL at the same site (composite histology) while 26 (23%) had FL at other sites (discordant histology). In the DLBCL+LG cohort, 16 (21.9%) had composite histology and 57 (78.1%) had discordant histology, predominantly in the bone marrow (55). LG histology included marginal zone lymphoma (18), chronic lymphocytic leukemia/small lymphocytic lymphoma (14) and lymphoplasmacytic lymphoma (4). Baseline characteristics were summarized in Table 1. Compared with de *novo* DLBCL patients, DLBCL+FL patients had less elevations in LDH and lower IPI scores, while DLBCL+LG patients had more advanced stages (all *P*<0.001). Cell of origin by Hans was predominantly GCB in DLBCL+FL (92.1% *vs* 61.4% in *de novo* DLBCL, *P*<0.001). The proportion of GCB subtypes in DLBCL+LG was similar to that in *de novo* DLBCL (50.9% *vs* 61.4%, *P*=0.132). The median follow-up was 83.9 months. DLBCL+FL patients had superior EFS (median 145.9 *vs* 101.9 months, EFS rate at 24 months [EFS24] 74.5% *vs* 63.9%, *P*=0.049) and OS (median not reached *vs* 139.7 months, *P*=0.004) compared with de *novo* DLBCL patients (Figure 1). DLBCL+LG patients had similar EFS (median 63.0 *vs* 101.9 months, EFS24 65.8% *vs* 63.9%, *P*=0.269) and OS (median 120.7 *vs* 139.7 months, *P*=0.624) compared with de *novo* DLBCL patients. Relapses with DLBCL or FL/LG were equally common in DLBCL+FL (7 relapses with DLBCL, 7 with FL, 6 with both) and DLBCL+LG patients (12 relapses with DLBCL, 12 with LG, 3 with both).

Figure 1. (A) EFS and (B) OS of Patients with *de novo* DLBCL, DLBCL+FL and DLBCL+LG

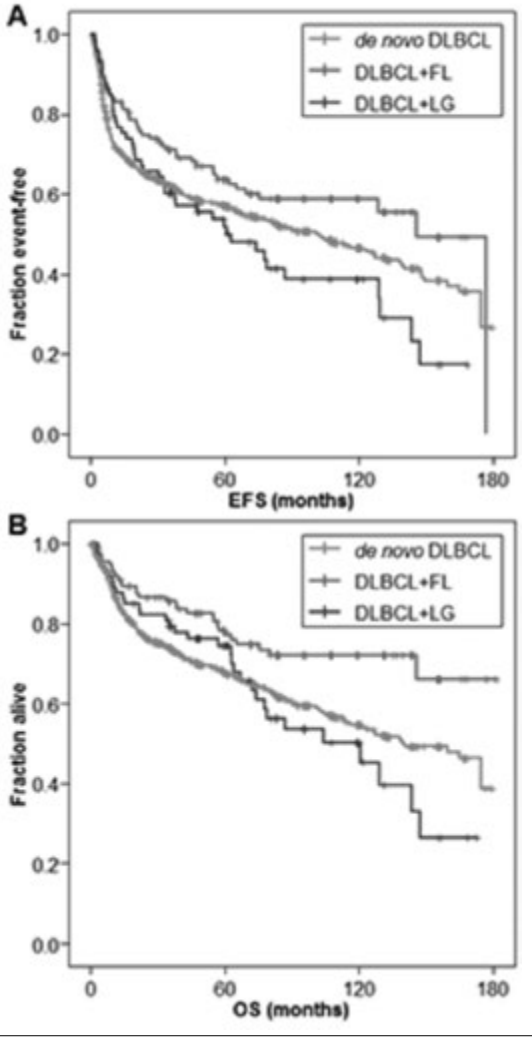

Figure 1.

Summary/Conclusion: Compared with *de novo* DLBCL patients, those with DLBCL+FL at diagnosis had predominantly GCB subtype of DLBCL, lower IPI scores, and improved EFS, EFS24 and OS, while those with DLBCL+LG had more advanced stages and similar outcomes. In DLBCL+FL and DLBCL+LG patients, relapses with DLBCL and FL or LG were equally common. DLBCL+FL likely behaves like GCB DLBCL, and this should be taken into consideration when including DLBCL+FL patients in DLBCL trials.

FAVOURABLE OUTCOMES WITH R-CODOX-M/R-IVAC ACROSS ALL SUBGROUPS OF AGGRESSIVE HIGH GRADE B-CELL LYMPHOMA: PATHOLOGY AND UPDATED SURVIVAL RESULTS FROM A PHASE 2 UK NCRI/LLR TRIAL

E.H. Phillips[1,*], C. Burton[2], A. Kirkwood[1], S. Barrans[2], A. Lawrie[1], S. Rule[3], R. Patmore[4], R. Pettengell[5], K. Ardeshna[6], S. Montoto[7], S. Paneesha[8], L. Clifton-Hadley[1], D. Linch[9], A. McMillan[10]

[1]Cancer Research UK and UCL Cancer Trials Centre, University College London, London, [2]Haematological Malignancy Diagnostic Service, Leeds, [3]Derriford Hospital, Plymouth, [4]Haematology, Castle Hill Hospital, Hull, [5]Clinical Sciences, St George's, University of London, [6]Haematology, University College Hospital London, [7]Haemato-oncology, Barts Health NHS Trust, [8]Haematology, Heart of England NHS Trust, [9]Cancer Institute, University College London, London, [10]Haematology, Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom

Background: Outcomes for patients (pts) with intermediate-high and high risk diffuse large B-cell lymphoma (DLBCL) after R-CHOP chemotherapy remain suboptimal but no other regimen has improved survival rates. Even less is known about the management of other forms of high grade B-cell lymphoma (HGBL) - double hit lymphoma (DHL) and HGBL not otherwise specified (NOS) - where outcomes are poor with no established standard of care. The phase 2 R-CODOX-M trial was designed to assess the efficacy of adding rituximab to the CODOX-M/IVAC regimen in high risk HGBL. Primary results have previously been presented (McMillan *et al.*, ICML 2015).
Aims: To present outcomes according to pathology subgroups and updated survival for both DLBCL/HGBL and Burkitt lymphoma (BL) cohorts.
Methods: Between 2009 and 2013, 150 pts were registered at 20 UK sites. Eligible pts were aged 18-65 years with stage II-IV untreated DLBCL/HGBL or BL and an International Prognostic Index (IPI) score ≥3. Pts received dose-modified CODOX-M and IVAC (Mead *et al.*, Blood 2008) with the addition of 8 doses of rituximab (375mg/m^2). Diagnostic pathology was centrally reviewed by the Leeds Haematological Malignancy Diagnostic

Service in 117 (78%) pts and diagnostic reports from central teaching hospitals were reviewed for the remainder. The original site diagnosis was changed from BL to DLBCL/HGBL in 11/36 (30.6%) pts and from DLBCL to BL in 4/114 (3.5%) following central review and FISH analysis. Six pts did not commence treatment and are excluded from further analyses.

Results: A total of 116 pts are included in the DLBCL/HGBL cohort. Median age was 50 years (range 18–65), IPI score was 3 (n=74; 64%), 4 (n=41; 35%) or 5 (n=1; 1%). Eleven pts (9.5%) had CNS involvement and 62 (53%) had a performance status (PS) ≥2. Cell of origin classification by Hans algorithm was available for 104 pts, of which 57 (55%) were germinal centre B-cell (GCB). FISH data was available for 57 pts, of which 7 (12%) were double/triple hit lymphomas. Five pts had HGBL-NOS (defined as a BL-like phenotype without *MYC*-R) and 4 pts were indeterminate between HGBL/BL due to failed FISH studies. With a median follow-up of 53 months for the whole DLBCL/HGBL cohort, 3-year progression-free survival (PFS) and overall survival (OS) were 68.4% (95% CI: 59-76.1; see Figure) and 76.2% (95% CI: 76.2–67.2), respectively. There was no difference in outcomes according to cell of origin (p=0.73), even excluding those with DHL, HGBL-NOS or indeterminate pathology. Three-year PFS rates were 57.1% for DHL (95% CI: 17.2–83.7) and 63.6% for those with HGBL-NOS/indeterminate histology (95% CI 29.7–84.5). Pts with secondary CNS lymphoma had a 3-year PFS of 72.7% (95% CI: 37.1–90.3). Treatment-related mortality was 4.3%; all were aged >50 years with a PS of 3. The BL cohort included 27 pts with a median age of 35 years (range 20–64). IPI score was 3 (n=13; 48%) or 4 (n=14; 52%); PS was ≥2 in 16 pts (59%) and 4 (15%) had CNS involvement. Three-year PFS and OS were 73.1% (95% CI: 51.7–86.2; Figure) and 76.4% (95% CI: 54.8–88.7), respectively.

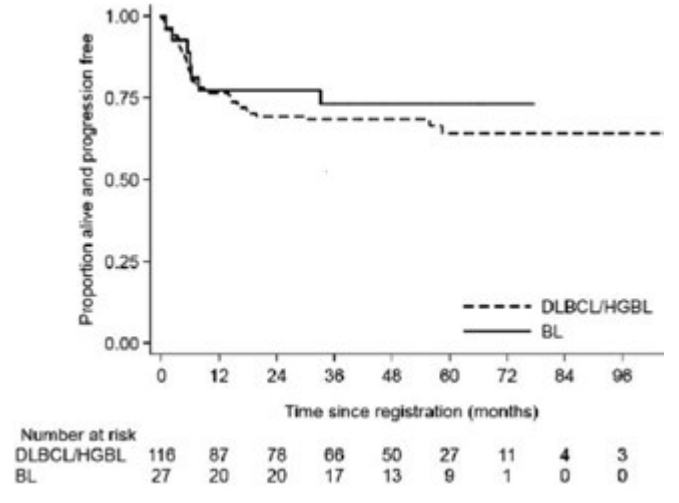

Figure 1.

Summary/Conclusion: These results demonstrate very good outcomes with R-CODOX-M/R-IVAC treatment in a high risk cohort of DLBCL/HGBL pts, similar to very high risk BL pts. For pts with aggressive HGBL, where urgent treatment is often necessary but accurate rapid diagnostic differentiation can be difficult, R-CODOX-M/R-IVAC is potentially a favourable treatment option offering improved outcomes for all diagnostic groups. Further trials are needed to assess this regimen against standard of care in high risk DLBCL/HGBL.

Background: The Italian phase III randomized study FIL-DLCL04 (Chiappella et al, Lancet Oncol 2017) showed that an abbreviated Rituximab-CHOP dose-dense chemotherapy followed by consolidation with Rituximab-high dose chemotherapy and autologous stem cell transplantation (R-HDC+ASCT) compared to a full course of R-CHOP dose-dense chemotherapy without consolidation, determined an advantage in term of failure-free survival (FFS) but no difference in overall survival (OS) in young patients with untreated diffuse-large B-cell lymphomas (DLBCL) at high-risk. The prognostic role of *TP53* is well-known in chronic lymphocytic leukaemia, but it has not yet been established in DLBCL.

Aims: Aim of this analysis was to correlate *TP53* mutations, cell of origin (COO) profile and the presence of biomarkers (MYC, BCL2), with OS and FFS.

Methods: From 2005 to 2010, 399 young untreated DLBCL at poor-risk, were enrolled in FIL-DLCL04 and randomized to receive R-HDC+ASCT in 199 and R-dose-dense in 200 (NCT00499018). *TP53* disruption by gene mutation was analyzed by Sanger DNA sequencing. COO classification as germinal center (GCB), activated B-cell (ABC) and unclassified was based on gene-expression profiling using the NanoString research use only lymphoma subtyping test. BCL2, MYC and TP53 were studied in immunohistochemistry (IHC); cases were deemed positive if at least 50%, 40% and 30% of lymphoma cells were stained with BCL2, c-MYC and TP53 antibodies, respectively. *Bcl2* and *Myc* translocations, copy gains and aberrations were tested by fluorescent *in situ* hybridization (FISH). OS and FFS were analyzed; a crude hazard ratio (HR) and an adjusted HR (aHR) for clinical characteristics (age, treatment, gender, age-adjusted International Prognostic Index, performance status, bone marrow involvement) and for biological factors (double-expressors, double-hit, COO profile) were calculated.

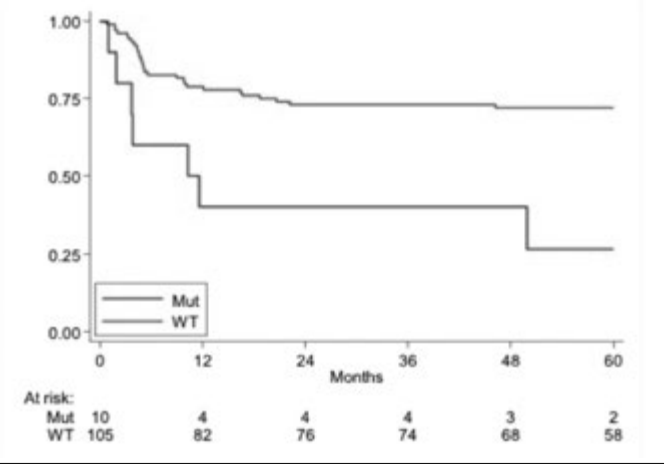

Figure 1.

Results: Of 399 DLBCL patients enrolled in FIL-DLCL04, 115 with tumor block available for subsequent analyses were analyzed for *TP53* mutation; no selection bias was observed between the 115 cases and the whole FIL-DLCL04 study population. Fifty-five of 115 patients (48%) received R-HDC+ASCT upfront, as for randomization arm; 22 (19%) had bone marrow involvement; 41 (53%) were GCB, 23 (29%) ABC and 14 (18%) unclassified; 20 (19%) were double-expressor (DEL) for MYC and BCL2 in IHC and 8 (8%) double-hit (DHL) for *Myc* and *Bcl2* in FISH. Regarding *TP53* status, 105 (91%) were wild type and 10 (9%) mutated; of 10 cases

with TP53 mutated, 5 were DEL, 2 DHL and 2 ABC. At a median follow-up of 72 months, 5-years FFS for TP53 mutated *versus* wild type were 27% (95% CI: 48-56) and 72% (95% CI: 62-80), respectively with a crude hazard ratio (HR) of 3.57 (95% CI: 1.56-8.17), p 0.003, an aHR (clinical) of 2.02 (95% CI: 0.75-5.44), p 0.165 and an aHR (biological) of 2.06 (0.70-6.11), p 0.190. (Figure 1). Five-years OS for TP53 mutated *versus* Wild type were 37% (95% CI: 10-66) and 84% (95% CI: 75-89), respectively; HR: 4.88 (95% CI: 1.91-12.42), p 0.001, aHR (clinical): 3.26 (95% CI: 0.98-10.9), p 0.055 and aHR (biological) 4.10 (0.89-18.86), p 0.070.
Summary/Conclusion: In this series of young patients with high risk DLBCL, *TP53* disruption by gene mutation identifies a very poor prognosis subgroup with a dismal FFS and OS, irrespective to IHC, FISH and COO profile. Likewise other hematological malignancies, *TP53* disruption is a negative prognostic factor also in DLBCL and these patients require different treatment with innovative drugs.

Background: Inhibition of protein phosphatase 2A tumor suppressor is essential for chronic myelogenous leukemia stem cell maintenance, evolution and innate anti-cancer immunity. In CML, persistance of quiescent LSCs, disease development and inhibition of NK cell growth and anti-cancer activity depend on cell-autonomous and bone marrow generated signals.
Aims: miR-300 interconnects CSCs, microenvironment and immune cells.
Methods: Exosomes purification, Cell Cycle analysis, LTC-IC and CFC assays, CFSE-mediated tracking of cell division, apoptosis assays, real time RT-PCR.
Results: We show that expression profiling of $CD34^+$ BM progenitors from healthy and CML patients CP and BC phase identified a number of miRs altered in CML and/or during BC transformation. We focused on miR-300 because it directly inhibited expression of multiple components of the PP2A inhibitory pathway and of other factors for LSC maintenance and disease progression, when ectopically expressed in CML but not in normal $CD34^+$ cells. MiR-300 acted as a potent tumor suppressor CML $CD34^+$ progenitors by inducing cell cycle exit and promoting spontaneous and (TKI)-induced apoptosis. In $CD34^+$ CML-BC progenitors miR-300 downregulation required the BCR-ABL1 kinase-dependent inhibition of C/EBPb, which was capable of binding and transcriptionally activating miR-300 promoter. Conversely, low O_2 levels and MSC-derived exosomes increased miR-300 expression in a TKI-insensitive manner to induce and/or preserve LSC quiescence and suppress NK cell growth. Indeed, lentiviral-mediated miR-300 inhibition in MSCs significantly prevented the MSC growth inhibitory activity on $CD34^+$ CML-BC and NK cells. Accordingly, miR-300 levels were found higher in $CD56^+CD3^-$ NK cells from CML patients at diagnosis compared to healthy individuals. Induction/maintenance of high miR-300 levels in LSCs required the hypoxia-induced inhibition of BCR-ABL1 activity and induction of C/EBPb expression/activity. LSCs escaped from the miR-300 apoptotic activity through an autocrine/paracrine mechanism that required the release by $CD34^+$ CML stem/progenitors of TGFb1 that, in turn, induced the expression of TUG1, a lncRNA acting as a miR-300 sponge. In fact, shRNA-mediated TUG1 suppression or Ab-dependent TGFb1 inhibition decreased the quiescent $CD34^+$ LSC number. By contrast, miR-300 inhibition did not alter LSC survival and self-renewal, further supporting a role for TUG1 as a miR-300 sponge. Accordingly, TUG1 was markedly induced in $CFSE^{MAX}$ but not dividing $CD34^+$ CML cells. In fact, low ectopic miR-300 expression induced growth arrest without affecting the number of $CFSE^{MAX}$ LSCs. High doses of miR-300 but not scramble oligonucleotides impaired LSC survival and self-renewal, induced a marked killing of quiescent LSCs and dividing $CD34^+$ CML progenitors, and impaired CML-BC engraftment in NRG-SGM3 mice.
Summary/Conclusion: In Summary, loss of miR-300 expression is essential for survival/proliferation of leukemic progenitors and, therefore, increased miR-300 expression is necessary for reduced NK cell number/activity and maintenance of the LSC reservoir. Induction of TUG1 may occur to preserve LSC survival after migration into the BM endosteal niche where quiescence is induced by MSCs and low O_2 levels through marked induction of intracellular miR-300 levels. Thus, disrupting the miR-300/TUG1 balance may represent a potential therapeutic approach for treatment/eradication of LSC-derived leukemias and restoration of innate immunity.

JAK1-STAT3 SIGNALING AXIS SUPPORTS LEUKEMIC STEM CELL PERSISTENCE IN CML

M.K. Kuepper[1], O. Herrmann[1], I.G. Costa[2], S. Koschmieder[1], T.H. Bruemmendorf[1], G. Mueller-Newen[3], M. Schemionek[1,*]

[1]Department of Hematology, Oncology, Hemostaseology and Stem Cell Transplantation, Faculty of Medicine, [2]Institute for Computational Genomics, [3]Institute of Biochemistry and Molecular Biology, RWTH Aachen University, Aachen, Germany

Background: Chronic myeloid leukemia (CML) is driven by the chromosomal translocation t(9;22) which transforms hematopoietic stem cells into leukemic stem cells (LCS). Blocking the oncogenic Bcr-Abl kinase by tyrosine kinase inhibitors (TKI) has greatly improved CML therapy, but is rarely curative as the disease-initiating LCS survive within the bone marrow (BM) niche independently of Bcr-Abl kinase activity. Recently, the signal transducer and activator of transcription 3 (STAT3) was shown to be highly activated in TKI-resistant CML cells that were supported by the BM microenvironment. However, while targeting STAT3 in combination with Bcr-Abl was potent to kill TKI-resistant LCS, the activating mechanism of persisting STAT3 activation remains unclear.
Aims: In this study, we first analyzed STAT3 activation in TKI treated leukemic cells, and how it is influenced by the BM microenvironment. Subsequently, we aimed to identify the mechanism allowing for TKI-persisting STAT3 activation and evaluated the therapeutic potential of combined Bcr-Abl and JAK1 inhibition using human cell lines, primary murine cells, as well as primary CML CD34$^+$ cells.
Methods: Gene Set Enrichment Analysis (GSEA) was performed using transgenic murine CML and control LSK cells. We generated conditioned medium (CM) by harvesting the supernatant of primary human mesenchymal stroma cells (MSC). qRT-PCR was performed to analyze target gene expression. Phosphorylation of STAT3 (pSTAT3^{Y705}) was evaluated by western blot upon Bcr-Abl (imatinib) and JAK1 (filgotinib/itacitinib) inhibition. Furthermore, an IL-6-blocking receptor fusion protein (RFP) was applied. Finally, colony forming unit (CFU) assay, CSFE staining and apoptosis analysis via flow cytometry of primitive CML CD34$^+$ cells were performed.
Results: GSEA pathway analysis revealed increased JAK/STAT signaling in transgenic CML LSK cells. We observed elevated STAT3 mRNA expression in KCL-22 (1.9-fold, p≤0.001) and CML MNC (1.6-fold, p≤0.05), as well as increased pSTAT3^{Y705} levels in murine Bcr-Abl BM, KCL-22 and CML-MNC upon imatinib treatment, exclusively in presence of MSC-derived CM. In the presence of JAK1- but not JAK2-specific inhibitors, persisting pSTAT3^{Y705} was decreased to basal levels in murine Bcr-Abl BM, KCL-22 and primary CML MNC. A similar effect was observed when applying an IL-6-blocking RFP. Combined inhibition of Bcr-Abl and JAK1 strongly reduced the CFU capacity of murine (2.2-fold, p≤0.001) and human CML cells (6.9-fold, p≤0.001) compared to IM treatment alone. Tracking the proliferation of CML CD34$^+$ cells by CSFE staining revealed that Bcr-Abl- and JAK1-inhibited cells showed increased quiescence (3.2-fold, p≤0.001) and decreased proliferation (3.6-fold, p≤0.001) compared to single treatments. Interestingly, combined Bcr-Abl and JAK1 inhibition strongly induced apoptosis even in quiescent LSC (2.4-fold, p≤0.001).
Summary/Conclusion: In the presence of BM microenvironment-derived CM, STAT3 is upregulated in Bcr-Abl leukemic cells upon oncogene inhibition. Here, we identified JAK1 as the STAT3-activating kinase in CML cells. JAK1 inhibition by TKIs decreases pSTAT3^{Y705} levels, blocks proliferation and reduces the CFU capacity. Upon Bcr-Abl and JAK1 inhibition, apoptosis is strongly induced compared to IM treatment alone in quiescent LCS. Our data demonstrate that persistent STAT3 activation is observed under IM treatment and supported by the microenvironment via JAK1 thus promoting LSC survival. As a consequence, JAK1 emerges as a potential therapeutic target for curative CML therapies.

S1552

MS4A3 REGULATES CELL SURFACE CYTOKINE RECEPTOR EXPRESSION, DIFFERENTIATION, AND DRUG RESISTANCE IN CHRONIC MYELOID LEUKEMIA

A. Eiring[1,*], J. Ahmann[1], J.-Y. Hwang[1], A. Senina[1], B. Helton[2], J. Khorashad[1], A. Pomicter[1], M. Zabriskie[1], A. Agarwal[3], R. Bell[1], C. Mason[1], H. Redwine[1], A. Bowler[1], P. Clair[1], S. Mc Weeney[3], V. Oehler[2], S. Varambally[4], J. Radich[2], K. Varley[1], T. O'Hare[1], M. Deininger[1]

[1]Huntsman Cancer Institute, The University of Utah, Salt Lake City, [2]Fred Hutchinson Cancer Research Center, Seattle, [3]Oregon Health & Science University, Portland, [4]University of Alabama Birmingham, Birmingham, United States

Background: We have previously demonstrated that the transcriptional profile of diagnostic CD34$^+$ cells from chronic phase chronic myeloid leukemia (CP-CML) patients exhibiting primary resistance to imatinib overlaps with that of patients with myeloid blast phase CML (BP-CML) (McWeeney *et al. Blood* 2010). These commonalities suggest that that primary TKI resistance and advanced disease are biologically related. Reduced expression of the hematopoietic cell cycle regulator, MS4A3, was identified as a principal component of the gene expression classifier predicting imatinib response.
Aims: The aim of this study was to identify the functional consequence of reduced MS4A3 expression in TKI resistance and blastic transformation of CML.
Methods: To assess the functional role of MS4A3 in CML and TKI response, we used ectopic MS4A3 expression and shRNA-mediated MS4A3 knockdown in CD34$^+$ cells from BP-CML and CP-CML patients, respectively. The phenotypic consequence of altered MS4A3 expression was measured using colony formation assays, apoptosis assays, long-term culture-initiating cell assays, and xenografts into NSG recipient mice.
Results: Low MS4A3 correlated not only with primary TKI resistance, but also with shorter overall survival in CP-CML (n=35). Microarray (n=19 CP-CML; n=16 BP-CML), qRT-PCR (n=22 CP-CML; n=17 BP-CML), and immunoblot (n=3 CP-CML; n=3 BP-CML) analyses demonstrated that MS4A3 mRNA and protein levels are reduced in CD34$^+$ progenitor cells from BP-CML *versus* CP-CML patients. Ectopic expression of MS4A3 in BP-CML CD34$^+$ progenitors (n=5) markedly reduced colony formation in the presence and absence of imatinib, consistent with a tumor suppressor role for MS4A3 in CML. While re-expression of MS4A3 alone did not increase apoptosis compared to controls, imatinib-induced apoptosis in BP-CML CD34$^+$ cells was increased by 62%, with no effect on normal CD34$^+$ cord blood cells (n=3). Conversely, shRNA-mediated MS4A3 knockdown (shMS4A3) in CP-CML CD34$^+$ cells (n=7) reduced the effects of imatinib in colony formation and apoptosis assays, with no effect on normal CD34$^+$ progenitors (n=4). These data suggest that MS4A3 positively regulates patient survival and imatinib response in CML progenitor cells. To evaluate MS4A3 in the leukemic stem cell compartment, qRT-PCR revealed that MS4A3 mRNA levels are markedly higher in committed CD34$^+$38$^+$ progenitors compared to more primitive CD34$^+$38$^-$ stem cells, suggesting a role for MS4A3 in differentiation. Flow cytometric analysis revealed that shMS4A3 in CP-CML CD34$^+$ cells reduced CD11b$^+$ cells by ~45% (n=3), which correlated with reduced cell surface expression of KIT, GM-CSFR, IL-3R, and FLT3R. To assess the function of MS4A3 in CML stem cells, we performed long-term culture-initiating cell (LTC-IC) assays and xenografts into NSG mice upon MS4A3 knockdown in CP-CML (n=3). shMS4A3 increased Ph$^+$ LTC-IC colony formation in the presence absence of imatinib. Consistent with these data, shMS4A3 enhanced engraftment of CD34$^+$CD45$^+$GFP$^+$ cells into the bone marrow of NSG recipient mice. DNA bisulfite conversion and patch PCR sequencing revealed that the MS4A3 promoter is highly methylated in CML compared to normal CD34$^+$ cells, but could not explain downregulation in BP-CML or TKI resistance. Rather, downregulation in the latter is due to loss of the myeloid-specific transcription factor, C/EBPbeta.
Summary/Conclusion: Altogether, these data suggest that MS4A3 plays a key role in 1) BCR-ABL1 kinase-independent resistance, 2) progression of CML from the chronic to the blastic phase of disease, and 3) in primitive CML stem cells *versus* progenitors.

S1553

THE COMBINATION OF THE MDM2 ANTAGONIST, IDASANUTLIN WITH NILOTINIB TARGETS PRIMITIVE CHRONIC MYELOID LEUKEMIA (CML) CELLS IN VITRO AND IN VIVO

M. Scott[1,*], C. Clarke[2], F. Warren[2], M. Drotar[2], H. Jorgensen[2], R. Hyde[2], C. Munje[2], R. Kinstrie[1], B. Higgins[3], L.-C. Chen[4], T. Holyoake[2], M. Copland[2], D. Vetrie[1]

[1]Institute of Cancer Sciences, [2]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom, [3]Roche Innovation Centre New York, [4]Roche Innovation Center New York, Roche Pharma Research and Early Development, New York, United States

Background: Treatment with tyrosine kinase inhibitors (TKIs) fails to eradicate leukemia stem cells (LSC) in CML patients necessitating life-long therapy. Our recent work has shown that both p53 and c-Myc control the survival and proliferation of primitive CML cells (Abraham et al, Nature 2016), and that modulating both p53 and c-Myc can target CML LSC. Clinically, modulators of p53 and/or c-Myc are likely to be given in combination with TKI.
Aims: As our ultimate aim is to introduce novel therapies into the clinic that eliminate CML LSC, we examined the effect the MDM2 antagonist,

idasanutlin ('Idasa') has in combination with nilotinib ('Nil') on leukemia cell numbers and LSC *in vitro* and *in vivo*.
Methods: We performed cell counts, apoptosis and cell cycle assays to determine combination indices (CI) and therefore synergy for drug combinations; and confirmed effects on primitive cells by long-term culture-initiating cell (LTC-IC) assay *in vitro*. To further examine the clinical utility of these drugs in CML we utilised our preclinical murine models: a patient derived xenograft (PDX) model and our double transgenic (DTG) SCL-tTA/BCR-ABL model.
Results: At the empirically derived ratio of 30:1 (Nil:Idasa) in primary CML CD34+ cells, the combination was synergistic by both cell count and apoptosis. At this ratio, the Nil/Idasa combination resulted in a significant increase in apoptosis compared to no drug control (NDC) or TKI alone ($p<0.05$; n=3), while no significance was reached for Nil/Idasa against normal samples (n=3). Nil/Idasa also resulted in a significant decrease in colony forming cell (CFC) counts compared to NDC or Nil alone ($p<0.05$; n=3), while no significant difference was seen in normal CD34+ cells. Moreover, by LTC-IC assay, compared to NDC, Nil/Idasa resulted in a significant decrease in output ($p<0.05$, n=3), while no significance was reached with the individual treatments. Again, no significant effect was seen in normal cells. Following transplant and long-term engraftment (12 weeks) of CML CD34+ cells into immunocompromised mice (PDX model), treatment with Idasa and Nil, either alone or in combination, resulted in a decrease in the percentage of human cells engrafted compared to vehicle alone, including the more primitive CD34+38- cells. However, while the percentage of human cells engrafted in the Nil-treated animals increased following 4 weeks recovery without drug, the percentage in the Idasa and combination arms remained the same, or even decreased. This was particularly evident in the more primitive cells, where Nil/Idasa combination resulted in the percentage of CD34+38- cells being significantly lower following recovery than both the vehicle and nil alone arms ($p=0.029$ & $p=0.0107$ respectively; n=4 vehicle / combo, n=3 Nil). In addition, when we treated our DTG CML mouse model with MDM2 antagonist (RG7112) and nil for 4 weeks following leukemia induction, we saw a significant decrease in the percentage of LSK cells in both the bone marrow and spleen with the combination compared to Nil alone ($p<0.01$ for both).
Summary/Conclusion: Overall these data show that pharmacological modulation of p53 in combination with TKI can target the most primitive CML cells, potentially in a synergistic manner. Moreover, recovery data from our PDX model suggests that this combination may abrogate the stem cell expansion which is seen with TKI alone following drug withdrawal, giving hope for treatment-free survival in patients. A planned clinical trial will test the efficacy of idasanutlin in combination with TKI.

THE MUTATIONAL LANDSCAPE IN HYDROXYCARBAMIDE-RESISTANT/INTOLERANT ESSENTIAL THROMBOCYTHEMIA TREATED ON THE MAJIC-ET STUDY

J. O'Sullivan[1,2,*], A. Hamblin[3], A. Panchal[4], C. Yap[4], S. Fox[4], S. Alimam[5], H. Dreau[3], K. Howard[3], P. Ware[3], M.F. Mc Mullin[6], C.N. Harrison[7], A.J. Mead[8]

[1]Haematopoietic Stem Cell Biology Laboratory, MRC Weatherall Institute of Molecular Medicine, Oxford, [2] Department of Hematology, Guy's and St Thomas' NHS Foundation Trust, London, [3]Department of Haematology, Oxford University Hospitals NHS Foundation Trust, Oxford, [4]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, [5]Department of Hematology, Guy's and St Thomas' NHS Foundation Trust, London, London, [6]Department of Haematology, Queen's University, Belfast, [7]Department of Haematology, Guy's and St Thomas' NHS Foundation Trust, London, [8]John Radcliffe Hospital, Weatherall Institute of Molecular Medicine, Oxford, United Kingdom

Background: MAJIC-ET a phase 2 study evaluated the role of ruxolitinib in hydroxycarbamide resistant/intolerant (HC-RES/INT) essential thrombocythaemia (ET). The impact of mutations in addition to recurrent driver mutations (*JAK2/CALR/MPL*) in RES/INT ET is currently unknown.
Aims: Here we expand the primary MAJIC-ET analysis to evaluate non-driver mutational profiles of MAJIC-ET patients (pts) using an ISO accredited Illumina TruSeq Custom Amplicon Panel, including 31 gene mutation hotspots & exons (~36,000 bp, 287 amplicons), followed by correlation with clinical outcomes.
Methods: Data was censored in January 2017 with 47.3% (n=52) randomised to best available therapy (BAT) & 52.7% (n=58) to ruxolitinib. Baseline clinical parameters including driver mutation status were matched.
Results: Overall, *JAK2*, *CALR* & *MPL* mutations were present in 48.6%, 30.3% & 4.6% of pts with 16.5% reported as "triple-negative". At one-year, responses were equivalent in BAT & ruxolitinib; 44.2% *vs* 46.6%, respectively, p=0.4. Molecular responses were rare, with complete molecular response (CMR) only in two *CALR*- & *JAK2*-mutated ruxolitinib & not BAT-treated pts. Additional mutations at baseline were detected in 29.1%. One additional mutation was present in 20% (n=22) & ≥2 mutations in 9.1% (n=10). The most frequently identified mutation was TET2 (n=14) followed by TP53 (n=8) & SF3B1 (n=7). The latter two detected at higher frequencies than previously reported in ET. TP53 mutations were more frequent in "triple-negative" (16.7%) than in *JAK2/CALR/MPL*-mutated pts (4.4%), p=0.087. Presence of additional mutations was not predictive of responses. Only one pt with a molecular response (partial) had a baseline additional mutation; *JAK2 V617F* co-mutated with *TP53*. Notably, one *CALR*-mutated pt with a CMR subsequently transformed to post-ET myelofibrosis with no additional mutation at baseline; mutational analysis at transformation is underway. Overall survival (OS) at 2 years was 95.7% in BAT & 93.6% in ruxolitinib-treated pts, p=0.264. OS was not affected by driver mutation status/allele burden or additional mutations. Transformation-free survival (TFS) at 2 years was similar in BAT (88.7%, 95% CI 77–94%) & ruxolitinib-treated pts (81%, 95% CI 70–88%), p=0.078. Presence of non-driver mutations was associated with increased risk of transformation (OR 8.1, 95% CI 1.9-33), p=0.003 & predictive of an inferior 2-year TFS of 67.2% (95% CI 54–77%) *vs* 94.2% (95% CI 86–97%) in pts with no additional mutations, p=0.003 (Figure 1). This remained significant on subgroup analysis of BAT-treated (p=0.016) but not for the ruxolitinib-treated pts.Presence of a TP53 mutation was associated with a poorer 2-year TFS: 54% (95% CI 31–72%) in TP53-mutated *vs* 88% (95% CI 80-92%) in TP53 non-mutated pts, p=0.042. TP53 mutations were not associated with prior busulfan/32P/Pipobroman. Presence of an SF3B1 mutation predicted a 2-year TFS of 57.1 (95% CI 34–74%) in SF3B1-mutated *vs* 89% (95% CI 82–93%) in SF3B1 non-mutated pts, p=0.001. High JAK2 allele burden (≥50%) did not predict transformation risk & neither JAK2 allele burden nor presence of additional mutations increased the risk of thrombotic events.

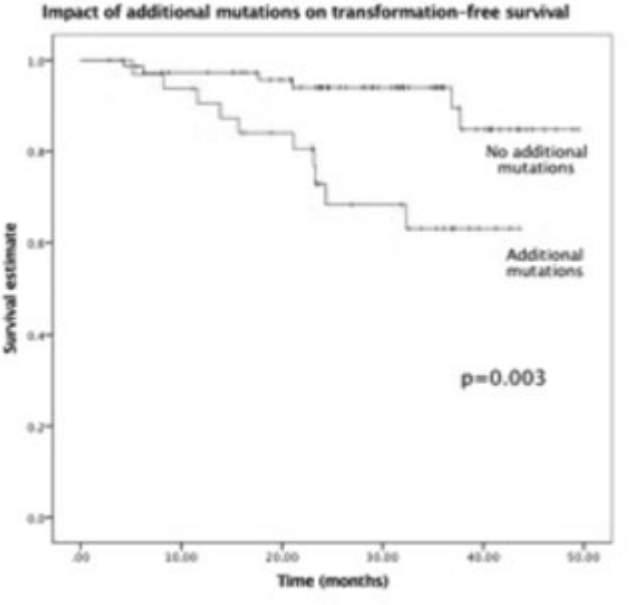

Figure 1.

Summary/Conclusion: We report for the first time a comprehensive mutational analysis of HC-RES/INT ET pts within the context of a clinical trial demonstrating a distinct mutational profile in this cohort. The presence of additional mutations was predictive for adverse TFS & we observed a high prevalence of TP53 & SF3B1 mutations. Our data highlight the clinical/prognostic utility of more extensive mutation screening in HC RES/INT ET.

Myelodysplastic syndromes – Clinical

S1555

A PHASE II CLINICAL TRIAL OF GUADECITABINE (SGI-110) FOR PATIENTS WITH PREVIOUSLY UNTREATED MYELODYSPLASTIC SYNDROME

G. Garcia-Manero[1,*], P. Bose[2], Y. Alvarado[2], G. Borthakur[2], N. Daver[2], F. Ravandi-Kashani[2], E. Jabbour[2], K. Takahashi[2], M. Andreeff[2], T. Kadia[2], C. DiNardo[2], J. Cortes[2], S. Kornblau[2], K. Naqvi[2], C. Benton[2], M. Ohanian[2], M. Konopleva[2], Z. Estrov[2], G. Montalban Bravo[2], S. Pierce[2], K. Bodden[2], H. Kantarjian[2]

[1]Leukemia, [2]MD Anderson Cancer Center, Houston, United States

Background: The hypomethylating agents (HMA) azacitidine and decitabine are the standard of care for most patients with higher risk myelodysplastic syndromes (MDS). Guadecitabine (SGI-110) is a next generation dinucleotide HMA with activity in patients with acute myelogenous leukemia and relapsed/refractory MDS. Here, we present results from a prospective ongoing single arm phase II trial for patients with previously untreated MDS.
Aims: The aim of this trial is to study the safety and clinical activity of guadecitabine in patients with previously untreated MDS.
Methods: Guadecitabine is administered at a dose of 60 mg/m2 subcutaneous daily x 5 days every 28 days. Supportive care measures such as transfusions and antibiotic therapy are allowed. Patients with int-2 or high risk MDS by IPSS (or more than 10% marrow blasts) not treated with prior chemotherapy are eligible. Patients could have received up to 1 cycle of prior HMA. Other inclusion criteria include age older than 17 years, adequate performance and renal and hepatic functions. Patients sign informed consent following institutional guidelines. The primary endpoint is achievement of a complete remission (CR). The study is designed with stopping rules for predetermined CR (stop if CR less than X in cohorts of 10 patients) or excess toxicity (cohorts of 5 patients). CR is defined as blasts less than 5% with complete peripheral blood recovery. Overall response rate is calculated using IWG 06 criteria. Toxicity is graded using CTCAE 4.0. Up to 100 patients are planned to be enrolled.
Results: In summary, 83 patients have been treated in this study. Median follow up is 8.6 months (range 1-38). Median age is 69 years (range 22 to 90) and 43% are older than 70 years. 49 patients (59%) are male. 13 (16%) have a diagnosis consistent with CMML. 66 (80%) patients have int-2 disease, 10 (12%) higher risk disease and 6 (7%) int-1 with more than 10% blasts. 46 (55%) patients had poor risk complex cytogenetics, 21 (25%) were diploid. An 81-gene NGS panel was used in all patients at baseline. Most frequent mutations by rank include: TET2 in 36 (43%) pts, TP53 in 25 (30%), ASXL1 in 22 (26%), RUNX1 in18 (21%), EZH2 in 17 (20%), DNMT3A in 13 (15%), IDH1 and NRAS in 10 (12%), GATA2 in 6 (7%). Median number of cycles administered is 5 (1 to 27). 70 patients (84%) are evaluable for response. CR was documented in 16 (23%), CRp in 3 (4%) and hematological improvement in 26 (37%) for an ORR of 64%. Complete marrow response with incomplete count recovery was considered as an HI. Median number of cycles to best response is 3 (1-12). Of note, 19 (23%) patients have received less than 3 cycles of therapy. The most common related toxicity has been infection. Only 2 (2%) patients have died during the first six weeks of therapy. Median overall survival is 14 months (1-38+). No association between cytogenetics or poor risk mutations and response was observed.
Summary/Conclusion: Guadecitabine (SGI-110) is clinically active and safe in this cohort of patients with higher risk MDS and poor risk features. Stopping rules have not been met and the study continues to accrue. Randomized trials will be required to compare guadecitabine with azacitidine or decitabine in the front line setting.

S1556

A RANDOMIZED PHASE II STUDY OF STANDARD DOSE AZACITIDINE ALONE OR IN COMBINATION WITH LENALIDOMIDE IN HIGH-RISK MDS WITH A KARYOTYPE INCLUDING DEL(5Q)

Background: Patients with high-risk MDS with 5q deletion have a poor prognosis and there is a need for improvement of the current standard azacitidine (AZA) treatment. Lenalidomide (LEN) is an effective treatment for patients with lower-risk MDS with del(5q), and we previously showed that monotherapy with high-dose LEN may have antitumor effects also in high-risk del(5q) myeloid disease. We hypothesized that an upfront combination of AZA and high-dose LEN would be more effective than AZA alone for patients with del(5q) and an approved indication for azacitidine treatment according to the EMA label.
Aims: We designed a Nordic MDS group prospective multicentre randomized phase II trial and evaluated the efficacy and safety of AZA +/- LEN.
Methods: Consecutive patients with high-risk MDS (IPSS INT-2 and high) and AML with multilineage dysplasia and 20-29 % blasts (previous RAEB-t) with a karyotype including del(5q) were included. Patients were randomized to standard dose of AZA 5-2-2 (75 mg/m^2/ d sc.) q 4 weeks for 6 cycles, or the same schedule of AZA+LEN. The initial dose of LEN was 10 mg daily 21/28 days. If well tolerated the dose was increased to 25 mg daily during cycle 4-6. The primary end point was response according to international working group (IWG) criteria. Secondary endpoints encompassed safety, AZA cycle interval between groups and survival. Informed consent was obtained.
Results: Seventy-two patients, from 12 centers in Sweden, Denmark, Norway and Finland were included between March 2012 and Jan 2017. Thirty-six patients were randomized to each arm. Median age was 71.5 years (35-84 yrs.). Thirty patients (41%) were female. Fifty-two (75%) patients were diagnosed with MDS and 18 (25%) patients with AML. According to IPSS the cytogenetic risk group was good in 8 patients (11%), intermediate in 4 patients (6%) and poor in 60 patients (83%). Serious adverse events were similar in the two groups. 47 patients (65%) completed 3 cycles and 40 patients (56%) completed the total treatment period. There was no difference in AZA cycle interval between the two groups. In the AZA+LEN arm, 7 out of 36 patients (19%), increased the lenalidomide dose to 25 mg/day during cycle 4-6. The overall response rate (ORR) was 36% for patients receiving AZA alone and 28% for AZA+LEN (P=0.85) and the corresponding marrow CR rates were 28% and 36%, respectively (P=0.45). At follow-up at 7 months (range, 0 to 36 months) after the last patient completed the trial the median survival was 14 months for patients receiving AZA and 10 months for the AZA+LEN arm (P=0.18). Nine patients (25%) in the AZA arm and eight patients (22%) in the AZA+LEN arm had a hematological improvement (P=0.81). Cytogenetic response (karyotype showing CR and PR) was achieved in 17% in the AZA arm and 28% in the AZA+LEN arm (P=0.13). Corresponding FISH analysis showed 39% in each group. After 3 cycles there was a trend towards a better cytogenetic response rate (FISH) in the AZA+LEN arm, 50% and 36%, respectively (P=0.052).
Summary/Conclusion: This is the first prospective randomized clinical trial in higher-risk MDS with a defined cytogenetic lesion. In this study with high-risk MDS and AML patients with del(5q) and a dismal prognosis the addition of LEN to standard AZA treatment did not improve overall response or survival but may indicate a stronger antitumor response after three cycles.

S1557

IMETELSTAT IN RBC TRANSFUSION-DEPENDENT (TD) LOWER RISK MDS RELAPSED/REFRACTORY TO ERYTHROPOIESIS-STIMULATING AGENTS (ESA) (IMERGE): UPDATED EFFICACY AND SAFETY

P. Fenaux[1,*], A. Raza[2], E. Vellenga[3], U. Platzbecker[4], V. Santini[5],

I. Samarina[6], K. Van Eygen[7], M. Díez-Campelo[8], M.M. Patnaik[9], L.J. Sherman[10], L. Sun[11], H. Varsos[11], E. Rose[11], A. Rizo[11], D.P. Steensma[12]

[1]Hôpital St Louis, Paris, France, [2]Columbia Presbyterian, New York, NY, United States, [3]UMCG, Groningen, Netherlands, [4]Universitätsklinikum Carl Gustav Carus Dresden, Dresden, Germany, [5]AOU Careggi, University of Florence, Florence, Italy, [6]Emergency Hospital of Dzerzhinsk, Nizhny Novgorod, Russian Federation, [7]AZ Groeninge – Oncology Centre, Kortrijk, Belgium, [8]Hosp. Clinico Univ. De Salamanca, De Salamanca, Spain, [9]Mayo Clinic Rochester, Rochester, MN, [10]Janssen Research & Development, LLC, Spring House, PA, [11]Janssen Research & Development, LLC, Raritan, NJ, [12]Dana-Farber Cancer Institute, Boston, MA, United States

Background: Patients with lower-risk MDS that is relapsed/refractory to ESA have few treatment options. The first-in-class telomerase inhibitor imetelstat, which targets cells with short telomere lengths and active telomerase, has the potential to provide clinical benefit in this patient population.
Aims: Here we report updated safety and efficacy data from IMerge, an ongoing 2-part, global, phase 2/3 study of imetelstat in RBC TD patients with IPSS Low or Intermediate-1 (Int-1) risk MDS.
Methods: The IMerge population includes patients with MDS relapsed/refractory to ESA with a transfusion requirement of ≥4 units over 8 weeks prior to entry and ESA-naïve patients with sEPO >500 mU/mL. In Part 1 (open-label, single-arm), imetelstat 7.5 mg/kg was administered IV every 4 weeks (escalation to 9.4 mg/kg permitted after 3 cycles). The primary endpoint is the rate of RBC transfusion-independence (TI) lasting ≥8 weeks; secondary endpoints include safety, ≥24-week TI rate, time to and duration of TI, and hematologic improvement (HI) rate. Updated results for the first 32 patients enrolled in Part 1 (median follow up, 75.3 weeks) are reported here.
Results: Median age was 68.5 years. 59% of patients were IPSS Low and 41% Int-1. 13 patients (43%) had sEPO>500 mU/mL. 34% had a cytogenetic abnormality, including 22% with del(5q). Prior MDS treatments included ESAs (88%), lenalidomide (38%), and decitabine or azacitidine (HMAs) (25%); 41% were both lenalidomide and HMA naïve and non-del(5q). As of Jan 2018, RBC-TI ≥8-week was achieved in 38% of patients. Median time to onset of TI was 8 weeks with a median duration of TI of 23 weeks. 16% of patients achieved ≥24-week TI, and 63% achieved erythroid HI. Of 13 lenalidomide and HMA naïve and non-del(5q) patients, 54% achieved ≥8-week TI. Median time to onset of TI in the subset was 8 weeks with a median duration of TI of 43 weeks. 31% of these patients had ≥24-week TI, and 69% achieved erythroid HI. TI response did not differ based on the presence of ringed sideroblasts or baseline sEPO level (41% [7/17] ≤500 mU/L; 38% [5/13] >500 mU/L). Cytopenias, particularly neutropenia and thrombocytopenia, were the most frequently reported adverse events (AEs) overall and in the lenalidomide/HMA naive and non-del(5q) subset. The subset had a lower incidence of gr ≥3 neutropenia relative to the overall population (54% *vs* 66%) but a higher rate of gr ≥3 thrombocytopenia (62% *vs* 53%). Gr 4 neutropenia incidences were 41% overall and 38% for the subset. Overall, 28 patients (88%) had reversible LFT elevations by at least one grade. Four patients had gr 3 worsening of AST and/or ALT (1 also had gr 3 worsening of bilirubin), all of which were reversible. Eleven patients received growth factors during the study for treatment of an AE or ongoing medical history (n=10) or as prophylaxis (n=1).
Summary/Conclusion: Safety and efficacy reported here support continued investigation of imetelstat using the current dosing regimen of 7.5 mg/kg every 4 weeks in IPSS Low/Int-1 RBC TD MDS patients relapsed/refractory to ESA. AEs (mostly cytopenias) were predictable, manageable, and reversible. TI was observed in 38% and erythroid HI in 63% of patients with imetelstat therapy, with a 16% durable 24-week TI rate. Patients naïve to lenalidomide and HMAs and who lacked del(5q) had a 54% 8-week TI rate and responses were more durable (31% 24-week TI rate). To further validate these findings, additional patients meeting these criteria have been enrolled and are currently being followed.

S1558

PHASE 1B/2 COMBINATION STUDY OF APR-246 AND AZACITIDINE (AZA) IN PATIENTS WITH TP53 MUTANT MYELODYSPLASTIC SYNDROMES (MDS) AND ACUTE MYELOID LEUKEMIA (AML)

Graber[8], N. Al Ali[1], E. Padron[1], R. Tell[9], J. Lancet[1], P. Fenaux[10], A. List[1], R. Komrokji[1]

[1]Malignant Hematology Department, H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL, [2]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Baltimore, MD, [3]Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA, United States, [4]Hematology Department, Cote D'azur University, Nice Sophia Antipolis University, Nice, France, [5]Department of Hematology and Medical Oncology, Cleveland Clinic, Cleveland, OH, [6]Department of Leukemia, MD Anderson Cancer Center, Houston, TX, [7]Weill Cornell Medical College, New York, NY, [8]Medical Affairs, Genoptix, Inc., Carlsbad, CA, United States, [9]Aprea Therapeutics, Stockholm, Sweden, [10]Hospital St Louis, Paris [7] University, Paris, France

Background: *TP53* mutant (m*TP53*) MDS and AML represent a distinct molecular cohort with poor outcomes. Hypomethylating agents (HMA) have emerged as preferred treatment for these patients with CR rate of 20-30% and median OS of 6-12 months. APR-246 is a mutant p53 activator with single agent activity in m*TP53* AML. We report preliminary phase 1b results of APR-246 + AZA in m*TP53* MDS/AML.
Aims: To evaluate the safety, recommended Phase 2 dose, preliminary activity and minimal residual disease (MRD) status of APR-246 in combination with azacitidine in m*TP53* MDS/AML.
Methods: Eligible pts included HMA naïve m*TP53* MDS and oligoblastic AML (≤30% blasts) ≥18 years of age. Pts received APR-246 in a 3+3 dose escalation design (50, 75, 100 mg/kg lean body weight) IV daily over 4 days in a lead-in phase (days -14 to -10) followed by the same dose of APR-246 (days 1-4) + AZA 75 mg/m^2 SC/IV over 7 days (days 4-10 or 4-5 and 8-12) in 28 day cycles. Primary objective was safety with AEs graded by CTCAE v4.03 and DLT assessment over 6 weeks. Secondary endpoints included response by IWG 2006 criteria as well as serial next generation sequencing (NGS) and p53 IHC for evaluation of clonal suppression and remission depth. For MRD analysis, a custom target-capture NGS assay was developed using unique molecular Identifiers for error correction with a limit of detection defined as ≥5 mutant reads and ≥1000 read depth.
Results: As of Feb 12th, 2017, 9 pts (33% male; median age 65 years (39-73)) have enrolled with 3 pts per cohort. Three pts had AML-MRC and 6 had MDS; all pts had poor risk cytogenetics (11% poor, 89% very poor) and higher risk disease by IPSS-R (22% high, 78% very high). Median BM blasts were 18% (4-30). Seven pts (78%) remain on study: 2 pts in the 50mg/kg cohort discontinued treatment (Tx), 1 pt due to infection during C2 who later died of sepsis unrelated to Tx, and 1 pt electively discontinued in durable marrow CR (mCR) after 5 cycles of therapy. Median time on study is 133 days (41-248). Tx related AEs during the lead-in phase (all G1) included ataxia (n=1), dizziness (n=1), nausea (n=2) and neuropathy (n=2). AEs occurring in > 1 pt included dizziness (n=3), nausea (n=6), neutropenia (n=6), thrombocytopenia (n=3), infection (n=4), headache (n=2), pain (n=3), weakness (n=2), xerostomia (n=2), mucositis (n=2), falls (n=3), neuropathy (n=4), and ataxia (n=2); all G1/G2 except neutropenia/thrombocytopenia (G4). No Tx-related SAEs or DLTs have occurred to date. Five of six pts were response evaluable with 1 pt discontinuing tx prior to 1st disease assessment. ORR by IWG was 100% with 4 CR (80%, 3/3 in DL2) and 1 mCR. All CR patients achieved complete cytogenetic response. One CR patient achieved a mCR and partial cytogenetic response after APR-246 lead-in prior to combination therapy. All CR pts had high p53 positivity by IHC at baseline (55-70%) which normalized on serial assessment (<5%). Serial NGS with a variant allele frequency (VAF) cutoff of 5% was negative in 80% of patients (4/5). In pts negative on serial NGS, MRD analysis was performed with median *TP53* VAF at maximum clearance of 0.8% (not detectable-3.4%) with 1 pt achieving MRD negativity after cycle 6 and 1 pt with VAF of 0.2% after cycle 3. The remaining 3 pts entered the study in Dec 17/Jan 18 with no response data available at data cutoff.

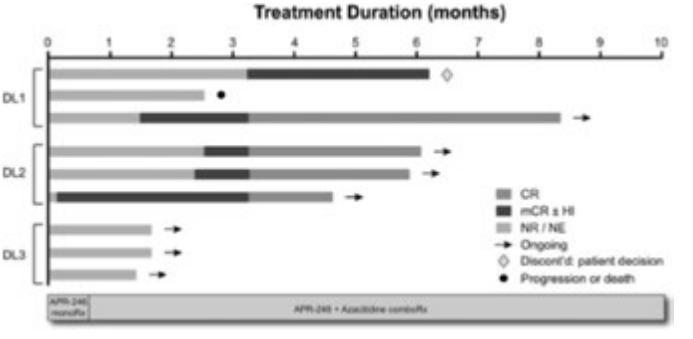

Figure 1.

Summary/Conclusion: APR-246 + AZA combination is well tolerated in m*TP53* MDS/AML. Responses have been achieved in all pts (80% CR) accompanied by deep molecular remissions. The maximum tolerated dose has not been reached and dose escalation is ongoing.

S1559

A MULTICENTER, RANDOMIZED, DOUBLE-BLIND PLACEBO-CONTROLLED STUDY OF DARBEPOETIN ALFA FOR THE TREATMENT OF ANEMIC PATIENTS WITH LOW OR INTERMEDIATE-1 RISK MYELODYSPLASTIC SYNDROME

U. Platzbecker[1,*], E.N. Oliva[2], A. Symeonidis[3], M. Delforge[4], J. Mayer[5], J.S. Goede[6], A. Guerci-Bresler[7], S. Badre[8], B.P. Mehta[8], C. De Oliveira Brandao[8]

[1]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik I, Dresden, Germany, [2]Azienda Ospedaliera Bianchi-Melacrino-Morelli, Reggio Calabria, Italy, [3]University of Patras Medical School, Patras, Greece, [4]University Hospital Leuven, Leuven, Belgium, [5]University Hospital Brno and Faculty of Medicine, Masaryk University, Brno, Czech Republic, [6]University Hospital and University of Zürich, Zürich, Switzerland, [7]CHU Brabois Vandoeuvre, Nancy, France, [8]Amgen Inc., Thousand Oaks, United States

Background: Many patients (pts) with lower-risk myelodysplastic syndrome (MDS) experience anemia. Transfusion is a treatment option; however, it is often associated with iron overload and other adverse effects. Erythropoiesis-stimulating agents (ESAs) are recommended to treat anemia in pts with MDS; however, long-acting ESAs, such as darbepoetin alfa (DAR), have limited phase 3 data supporting this indication.
Aims: To assess long-term follow-up (LTFU) and survival in anemic pts with low or int-1–risk MDS who received DAR or placebo (PBO).
Methods: This is the final analysis from the LTFU of a phase 3, randomized (2:1), PBO-controlled trial (NCT01362140) that enrolled European pts with anemia and low/int-1 IPSS–risk MDS. Pts had not previously received ESAs or disease-modifying agents for MDS. Primary analysis results have been published (Platzbecker *et al.* Leukemia 2017). The study comprised a 3-wk screening period and a 24-wk double-blind (DB) treatment period; pts subsequently crossed over to a 48-wk open-label (OL) treatment phase and then LTFU for up to 3 years on study during which physicians could prescribe any therapy. Pts received DAR 500 µg Q3W, adjusted to maintain hemoglobin at 11–12 g/dL. Endpoints were incidence of RBC transfusion and IWG 2006 erythroid response in the DB and OL phases, and survival and disease progression to acute myeloid leukemia (AML) in LTFU.
Results: 98 pts received DAR and 48 received PBO. 55% were men and mean age was 72 years. In the DB phase, transfusion rates were 36% for DAR and 59% for PBO; erythroid response rates were 15% for DAR *vs* 0% for PBO (P=0.016). There were 41 deaths during the study; 27 pts (28%) in the DAR group and 14 pts (29%) in the PBO group. Most pts died during LTFU (DAR, 93% and PBO, 79%) and were int-1 at baseline (DAR, 56% and PBO, 71%). Survival curves are presented (**Fig 1A**). 10 pts progressed to AML (**Table 1.**). Median time to AML progression was not reached in either treatment group (**Fig 1B**).
Summary/Conclusion: In this study, there were no differences in rates of death (mostly reported in LTFU) or AML between DAR and PBO arms. Pts with int-1 risk MDS had worse prognosis. Findings are limited because the study was not powered to detect differences in survival and pts could receive any therapy of physician's choice in LTFU. In conclusion, DAR is a safe treatment and lowered transfusion rates associated with anemia of low/int-1 risk MDS.

Table 1. Pts who progressed to AML during the study.

Treatment group (Pt response per MDSAC)	IPSS at baseline	MDS duration at baseline, days	Highest DAR dose	Day of first progression to AML	Study period
PBO	int-1	82	0	46	DB
PBO	int-1	208	0	175	LTFU
PBO	int-1	91	Q3W	379	LTFU
DAR	int-1	61	Q3W	64	DB
DAR	low	247	Q3W	146	DB
DAR	int-1	85	Q3W	195	LTFU
DAR	int-1	76	Q3W	254	OL
DAR (pt had response from wks 37–45)	int-1	80	Q2W	489	OL
DAR	int-1	191	Q2W	788	LTFU
DAR (pt had response from wks 10–37)	low	296	Q2W	743	LTFU

IVOSIDENIB (AG-120) IN MUTANT IDH1 RELAPSED/REFRACTORY ACUTE MYELOID LEUKEMIA: RESULTS OF A PHASE 1 STUDY

D.A. Pollyea[1,*], C.D. Di Nardo[2], S. de Botton[3], E.M. Stein[4], G.J. Roboz[5], A.S. Mims[6], R.T. Swords[7], J.K. Altman[8], R.H. Collins[9], G.N. Mannis[10], G.L. Uy[11], W.B. Donnellan[12], A. Pigneux[13], A.T. Fathi[14], H. Liu[15], B. Wu[15], E.C. Attar[15], M.S. Tallman[4], R.M. Stone[16], H.M. Kantarjian[2]

[1]University of Colorado School of Medicine, Aurora, [2]University of Texas MD Anderson Cancer Center, Houston, United States, [3]INSERM U1170, Institut Gustave Roussy, Villejuif, France, [4]Memorial Sloan Kettering Cancer Center, [5]Weill Cornell Medical College, New York, [6]Ohio State University Wexner Medical Center, Columbus, [7]Sylvester Comprehensive Cancer Centre, Miami, [8]Northwestern University, Chicago, [9]University of Texas Southwestern Medical Centre, Dallas, [10]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, [11]Washington University School of Medicine, St Louis, [12]Sarah Cannon Research Institute, Nashville, United States, [13]CHU de Bordeaux, Bordeaux, France, [14]Massachusetts General Hospital Cancer Center, Boston, [15]Agios Pharmaceuticals, Inc., Cambridge, [16]Dana-Farber Cancer Institute, Boston, United States

Background: Ivosidenib (IVO; AG-120) is an oral, targeted inhibitor of mutant isocitrate dehydrogenase 1 (mIDH1) that is being evaluated in a phase 1 dose escalation and expansion study of mIDH1 advanced hematologic malignancies (NCT02074839).
Aims: To report updated efficacy and safety data from all patients with relapsed/refractory acute myeloid leukemia (R/R AML) receiving IVO 500 mg once daily (QD).
Methods: All patients provided written informed consent. The primary efficacy endpoint was the CR+CRh rate (complete remission [CR] according to modified IWG 2003 criteria plus CR with partial hematologic recovery [CRh]). CRh was defined as absolute neutrophil count >0.5×10^9/L *and* platelet count >50×10^9/L. The overall response rate (ORR) comprised CR, CR with incomplete hematologic or platelet recovery, partial response, and morphologic leukemia-free state. The data cutoff date for this analysis was Nov 10, 2017.
Results: A total of 258 patients were treated with IVO. Among 179 R/R AML patients who received IVO 500 mg QD, 17 (9.5%) remained on treatment at data cutoff. In R/R AML patients, the CR+CRh rate was 31.8% (95% CI: 25.1%, 39.2%), including CR in 24.0% (95% CI: 18.0%, 31.0%). Median duration of CR+CRh was 8.2 months (95% CI: 5.6, 12.0), and median duration of CR was 10.1 months (95% CI: 6.5, 22.2). The ORR was 41.9% (95% CI: 34.6%, 49.5%). Treatment was well tolerated; the most common adverse events (AEs) of any grade, irrespective of causality and occurring in ≥25% of 179 R/R AML patients were diarrhea (33.5%), leukocytosis (31.3%), nausea (31.3%), febrile neutropenia (29.1%), fatigue (28.5%), and electrocardiogram QT prolonged (25.7%). The majority of these AEs were grade 1–2 and unrelated to treatment. IDH differentiation syndrome (IDH-DS) was reported in 19 of 179 (10.6%) patients, including grade ≥3 IDH-DS in 9 (5.0%); study drug was held owing to IDH-DS in 6 patients (3.4%), and no instances of IDH-DS led to dose reduction, permanent treatment discontinuation, or death. Updated mutation clearance results will be provided.
Summary/Conclusion: In a high-risk, molecularly defined R/R AML patient population, IVO induced durable remissions and was well tolerated. Studies in previously untreated AML populations are ongoing.

S1561

ENASIDENIB MONOTHERAPY IS EFFECTIVE AND WELL-TOLERATED IN PATIENTS WITH PREVIOUSLY UNTREATED MUTANT-IDH2 (MIDH2) ACUTE MYELOID LEUKEMIA (AML)

D.A. Pollyea[1,2,*], M.S. Tallman[3,4], S. de Botton[5,6], C.D. Di Nardo[7], H. Kantarjian[7], R. Collins[8], A.S. Stein[9], Q. Xu[10], A. Tosolini[10], J. Van Oostendorp[10], S.V. Agresta[11], E.M. Stein[3,4]

[1]University of Colorado School of Medicine, [2]University of Colorado Denver, Aurora, [3]Memorial Sloan Kettering Cancer Center, [4]Weill Cornell Medical College, New York, United States, [5]Gustave Roussy, Villejuif, [6]Univ Paris Sud, Université Paris-Saclay, Le Kremlin-Bicêtre, France, [7]The University of Texas MD Anderson Cancer Center, Houston, [8]University of Texas Southwestern Medical Center, Dallas, [9]City of Hope Comprehensive Cancer Center, Duarte, [10]Celgene Corporation, Summit, [11]Agios Pharmaceuticals, Inc., Cambridge, United States

Background: Enasidenib (AG-221) is an oral inhibitor of mIDH2 proteins. In the phase 1/2 AG221-C-001 trial, enasidenib was associated with an overall response rate (ORR) of 40.3% and median overall survival (OS) of 9.3 months in patients (pts) with relapsed/refractory m*IDH2*-AML (Stein, *Blood*, 2017). Older pts with untreated AML who are not candidates for standard induction chemotherapy due to advanced age, poor performance status, comorbidities, poor-risk cytogenetics, or other factors, pose a therapeutic challenge.
Aims: Determine clinical outcomes for older pts with previously untreated m*IDH2* AML receiving enasidenib monotherapy in the AG221-C-001 study (NCT01915498).
Methods: Pts aged ≥60 years with previously untreated AML who were not candidates for standard treatment (Tx), with ECOG performance status scores of 0-2 were eligible. Pts in the phase 1 dose-escalation received enasidenib doses of 50-650 mg/day, and all pts in the phase 1 expansion and phase 2 received enasidenib 100 mg/day, in continuous 28-day Tx cycles. Response was assessed per modified IWG response criteria for AML. Safety was assessed by Tx-emergent adverse event (TEAE) reporting.
Results: Of all 345 study pts, 39 (11%) had previously untreated m*IDH2* AML. At data cutoff (1 Sep 2017), 3 pts in complete remission (CR) continued to receive study drug, 2 pts in cycle 27 and 1 in cycle 35. At entry, median age was 77 years (range 58-87), 26% of pts had NCCN poor-risk cytogenetics, and 22 pts (56%) had an antecedent hematological disorder (AHD), including 17 with prior diagnosis of MDS. Median time from diagnosis was 1.0 month (range 0.1-4.7). Median number of enasidenib Tx cycles was 6.0 (range 1-35). Seven pts (18%) attained CR; estimated median durations of CR and of any response were not reached (NR) (**Table**). ORR was 30.8% (95%CI 17.0, 47.6). Times to first and best responses were 1.9 and 3.7 months, respectively. Three pts proceeded to transplant and were alive at data cutoff. At median follow-up of 8.4 months, median OS was 11.3 months (95%CI 5.7, 15.1) and event-free survival was 5.7 months (2.8, 16.0). Median OS in responding patients (n=12) was NR (95%CI 10.4, NR). The most frequent TEAEs (any grade or cause) were fatigue (44%), decreased appetite (41%), and nausea and constipation (38% each). The most frequent Tx-related TEAEs were hyperbilirubinemia (31%) and nausea (23%). The only serious Tx-related TEAEs reported for >1 pt were IDH differentiation syndrome (n=5, 13%) and tumor lysis syndrome (n=2, 5%). Tx-related TEAEs led to dose modifications for 3 pts (8%), dose interruptions for 9 pts (23%), and Tx discontinuation for 2 pts (5%).

Table 1.

Enasidenib Efficacy in Patients with Previously Untreated *mIDH2* AML (N=39)	
Overall response rate (ORR),* *n* (%)	**12 (30.8)**
ORR 95%CI	17.0, 47.6
Best response, *n* (%)	
CR	7 (18)
CRi/CRp	1 (3)
PR	2 (5)
MLFS	2 (5)
Stable Disease,† *n* (%)	19 (49)
Disease Progression, *n* (%)	1 (3)
Not evaluable,‡ *n* (%)	7 (18)
Overall survival, months, median (95% CI)	11.3 (5.7, 15.1)
Event-free survival, months, median (95% CI)	5.7 (2.8, 16.0)
Time to CR, months, median (range)	5.6 (3.4-12.9)
Duration of CR, months, median (95% CI)	NR (3.7, NR)
Time to first response, months, median (range)	1.9 (1.0-3.8)
Time to best response, months, median (range)	3.7 (1.0-12.9)
Duration of any response, months, median (95% CI)	NR (7.4, NR)

*Overall response rate included complete remission (CR), CR with incomplete count recovery (CRi/CRp), partial remission (PR), and morphologic leukemia-free state (MLFS), per modified IWG 2003 response criteria for AML
†Failure to achieve a response but not meeting criteria for progressive disease for a period of ≥8 weeks
‡Due to discontinuation before a response assessment
NR, not reached

Summary/Conclusion: Enasidenib induced hematologic responses in approximately one-third of these older pts with previously untreated m*IDH2* AML who were not candidates for standard Tx, and more than

one-half of whom had an AHD. Approximately 1 in 5 of these pts attained CR during enasidenib monotherapy. Responses were durable: median duration of any response was not reached. Median OS was also promising (11.3 months) in this cohort with median age 77 years; pts aged >65 have an estimated median OS of only ~5 months, even when treated (Medeiros, *Ann Hematol*, 2015). Tx-related TEAEs were infrequent and led to discontinuation for only 2 pts. These results suggest enasidenib may benefit older adults with m*IDH2* AML who are not fit to receive cytotoxic regimens. Enasidenib is under study in a similar AML patient population in the Beat AML Master Trial (NCT03013998).

S1562

MUTANT IDH (MIDH) INHIBITORS, IVOSIDENIB OR ENASIDENIB, WITH AZACITIDINE (AZA) IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

Arnan Sangerman[14], B. Wu[15], D.O. Koralek[15], J. Van Oostendorp[16], J. Gong[16], K.J. Mac Beth[16], P. Vyas[17]

[1]The University of Texas MD Anderson Cancer Center, Houston, [2]City of Hope Comprehensive Cancer Center, Duarte, [3]Memorial Sloan Kettering Cancer Center, [4]Weill Cornell Medical College, New York, [5]Massachusetts General Hospital Cancer Center, [6]Harvard Medical School, Boston, United States, [7]Princess Margaret Cancer Centre, Toronto, Canada, [8]Hospital Universitari i Politecnic La Fe, Valencia, Spain, [9]University of Chicago Medicine and the University of Chicago Comprehensive Cancer Center, Chicago, [10]Dana-Farber Cancer Institute, Boston, [11]University of Texas Southwestern Medical Center, Dallas, United States, [12]University of Bologna, Bologna, [13]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy, [14]ICO-Hospital Duran i Reynals, Barcelona, Spain, [15]Agios Pharmaceuticals, Inc., Cambridge, [16]Celgene Corporation, Summit, United States, [17]MRC Molecular Haematology Unit and Oxford Biomedical Research Centre; University of Oxford and Oxford University Hospitals, Oxford, United Kingdom

Background: *IDH1* and *IDH2* mutations occur in approximately 20% of patients with AML, with increasing frequency in older patients. Ivosidenib (AG-120) and enasidenib (AG-221) are oral small-molecule inhibitors of mIDH1 and mIDH2 proteins, respectively, both shown to promote myeloid differentiation. As monotherapies, enasidenib and ivosidenib induced clinical responses in patients (pts) with mIDH relapsed/refractory AML. AZA monotherapy prolonged survival *vs* conventional care in older pts with newly diagnosed (ND) AML. AZA reduces DNA methylation by inhibiting DNA methyltransferases, and mIDH inhibitors indirectly reduce DNA methylation by suppressing the oncometabolite, 2-HG, and restoring function to -ketoglutarate-dependent TET family enzymes. *In vitro*, mIDH inhibitor + AZA combinations enhanced cell differentiation and apoptosis.
Aims: Evaluate clinical outcomes with combination mIDH inhibitors + AZA in older pts with ND-AML in an ongoing phase 1b/2 study (NCT02677922).
Methods: Adult pts with m*IDH* ND-AML ineligible for intensive treatment (Tx) and ECOG PS scores ≤2 were eligible. Pts received ivosidenib (mIDH1) 500 mg QD or enasidenib (mIDH2) 100 or 200 mg QD, plus SC AZA 75 mg/m^2 x 7d, in continuous 28d cycles. Response was defined by modified IWG 2003 AML criteria; overall response rate (ORR) included complete remission (CR), CR with incomplete count recovery (CRi/CRp), partial remission (PR), and morphologic leukemia-free state (MLFS).

Table 1.

Grade 3-4 hematological AEs

	IVO 500 mg + AZA (n=11)	ENA 100 mg + AZA (n=3)	ENA 200 mg + AZA (n=3)
	n		
Thrombocytopenia	1	0	1
Anemia	2	0	1
Febrile neutropenia	2	0	1
Neutropenia	1	0	2
Lymphocyte decrease	0	0	1
WBC decrease	0	0	1

Results: At data cutoff (Sep 1, 2017) 17 pts had received ivosidenib 500 mg (n=11) or enasidenib 100 mg (n=3) or 200 mg (n=3) + AZA in the phase 1b portion of the study; 11 pts were ongoing. *Ivosidenib:* Median age was 76 yrs (range 74-82) and 82% of pts had an ECOG PS score of 1. Median number of Tx cycles was 3 (range 1-13). Three pts discontinued Tx, 2 due to progressive disease (PD). AEs in ≥4 pts (any grade) were nausea (n=8), constipation (6), fatigue (5) and diarrhea (4). Grade 3-4 hematological AEs (**Table 1**) occurred at similar frequency to what has been reported for AZA alone. Serious AEs in >1 pt were pneumonia and febrile neutropenia (n=2 each). Eight of 11 pts responded: 4 pts attained CR, 1 CRi, 1 PR, and 2 MLFS. *Enasidenib:* Median age was 68 yrs (range 65-76) and 83% of pts had an ECOG PS score of 1. Median number of Tx cycles was 9 (1-13). Three pts discontinued Tx, 2 due to PD. Most common AEs (any grade) were nausea and hyperbilirubinemia (n=4 each). Serious AEs in >1 pt were pyrexia, bilirubin increase, pneumonia (n=2 each). Four of 6 pts responded: 2 pts achieved CR, 1 PR, and 1 MLFS.
Summary/Conclusion: mIDH inhibitor + AZA regimens were generally well tolerated in these older pts with ND-AML; 65% of pts remained on-study at data cutoff. The most common AEs were grade 1-2 gastrointestinal events and enasidenib-related indirect bilirubin elevations, likely due to off-target inhibition of the UGT1A1 enzyme. Response rates are encouraging. Phase 1b enrollment completed in late 2017; updated data for all 23 ivosidenib and 6 enasidenib pts will be presented, as well as longitudinal changes in m*IDH* variant allele frequencies. Enrollment continues in the phase 2 portion of this study (enasidenib + AZA) and in the phase 3 AGILE study of ivosidenib+ AZA (NCT03173248).

S1563

DURABLE RESPONSE WITH VENETOCLAX IN COMBINATION WITH DECITABINE OR AZACITADINE IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

C.D. Di Nardo[1,*], K. Pratz[2], J. Potluri[3], V. Pullarkat[4], B.A. Jonas[5], A.H. Wei[6], P.S. Becker[7], O. Frankfurt[8], T. Xu[3], W.-J. Hong[9], B. Chyla[3], D.A. Pollyea[10], A. Letai[11]

[1]Department of Leukemia, The University of Texas MD Anderson Cancer Center, Houston, [2]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins University, [3]AbbVie, Inc., North Chicago, [4]Department of Hematology and Hematopoietic Cell Transplantation and Gehr Family Center for Leukemia Research, City of Hope National Medical Center, Duarte, [5]University of California Davis Comprehensive Cancer Center, Sacramento, [6]The Alfred Hospital and Monash University, Melbourne, [7]Clinical Research Division, Fred Hutchinson Cancer Research Center and Division of Hematology, Department of Medicine, University of Washington School of Medicine, Seattle, [8]Northwestern University Feinberg School of Medicine, Chicago, [9]Genentech, Inc., South San Francisco, [10]University of Colorado School of Medicine, Aurora, [11]Department of Medical Oncology, Dana-Farber Cancer Institute, Boston, United States

Background: Venetoclax (VEN), an oral BCL-2 inhibitor, has synergistic activity when combined with hypomethylating agents.
Aims: This clinical study explores the optimal dose and efficacy of VEN in combination with decitabine (DEC) or azacitadine (AZA) in elderly AML.
Methods: This is an open-label, phase 1b, dose escalation and expansion study (NCT02203773) on the safety and efficacy of VEN, with DEC or AZA, in elderly patients (≥65 years) with untreated AML. VEN was coadministered daily with 20 mg/m^2 of DEC on days 1-5 or 75 mg/m^2 of AZA on days 1-7, each 28 day cycle. VEN was dosed at 400, 800, or 1200 mg in the escalation phase, and 400 or 800 mg in the expansion phase. Complete remission (CR), CR with incomplete blood count recovery (CRi), overall survival (OS) and adverse events (AEs) were evaluated.

Table 1.

Patient subgroup	n	CR/CRi n (%)	Duration of CR/CRi median months	OS
All VEN doses	145	97 (67)	11.3	17.5
Intermediate cytogenetic risk	74	55 (74)	12.9	NR
Poor cytogenetic risk	71	42 (59)	6.7	9.6
Secondary AML	36	24 (67)	NR	NR
Age ≥75 years	62	40 (65)	9.2	11.0
VEN 400 mg				
+ AZA	29	22 (76)	NR	NR
+ DEC	31	22 (71)	12.5	15.2
VEN 800 mg				
+ AZA	37	21 (57)	11.7	14.2
+ DEC	37	27 (73)	9.2	17.5

OS, overall survival; NR, not yet reached (if applicable)

Results: Data cutoff was July 7, 2017. Of 145 patients, 56% were male; the median age was 74 years (range: 65–86). Overall, 60, 74, and 11 patients received VEN at 400, 800, and 1200 mg, respectively. Key grade ≥3 AEs were febrile neutropenia (43%), thrombocytopenia (23%) and neutropenia (16%); pneumonia and bacteremia (all grades) occurred in 18% and 8% of patients, respectively. At 400mg of VEN, the rate of CR+CRi was 73% (76% with AZA and 71% with DEC); efficacy data are in the table. Minimal residual disease (MRD) assessment in marrow aspirates was performed at disease assessment in a central lab using multicolor flow cytometry assay;

overall, 37% (36/97) of patients with CR/CRi had MRD levels below the 10^{-3} cutoff. Median follow up was 15.1 months.
Summary/Conclusion: Preliminary data suggest that 400 mg of VEN has the optimal benefit-risk profile in combination with DEC or AZA, which demonstrated a tolerable safety profile with deep responses and durable outcomes in elderly patients with AML.

S1564

CHEMOTHERAPY AND VENETOCLAX IN ELDERLY AML TRIAL (CAVEAT): A PHASE 1B DOSE ESCALATION STUDY EXAMINING MODIFIED INTENSIVE CHEMOTHERAPY IN FIT ELDERLY PATIENTS

A.H. Wei[1,*], I.S. Tiong[1], A.W. Roberts[2], C.Y. Fong[3], C.C. Chua[1], S.B. Ting[4], J. Nguyen[1], F. Yuen[1], R. Hall[1], S. Fleming[1], J. Reynolds[5]

Background: Venetoclax (VEN) is a potent, small molecule BH3-mimetic targeting pro-survival BCL-2 with an emerging role for treatment of elderly patients with Acute Myeloid Leukemia (AML) unfit for intensive chemotherapy in combination with low-dose cytarabine (LDAC)(Wei *et al*, ASH 2017) or hypomethylating agents (HMA)(Di Nardo *et al*, Lancet Oncol 2018). The optimal dose of VEN was 600mg and 400mg in the LDAC and HMA studies, respectively. The feasibility of combining VEN with more intensified chemotherapy regimens has yet to be reported.
Aims: To evaluate the optimal dose, safety and efficacy of VEN in combination with dose-modified intensive chemotherapy in older patients with AML.

[a] Secondary AML includes antecedent myelodysplastic syndrome (n=10), myeloproliferative neoplasm (n=3), therapy-related myeloid neoplasm (n=2), and chronic myelomonocytic leukemia (n=1).
[b] 2 subjects received ≥7 days of VEN but did not commence chemotherapy due to sepsis (n=1) or deterioration of ECOG (n=1).
[c] 1 subject each in cohorts D and E respectively were still receiving induction.
[d] Among patients who achieved CR/CRi. D1 is the first day of chemotherapy (i.e. day 8 of study protocol).
[e] After induction, 1 subject each in cohorts A and B respectively continued therapy without reaching platelets ≥50x10⁹/L.
[f] After first continuation, 1 subject in cohort D did not reach neutrophils ≥1.0x10⁹/L and platelets ≥50x10⁹/L, 1 subject in cohort B did not achieve nadir neutrophil <1.0x10⁹/L.
Abbreviations: AML, acute myeloid leukemia; CR, complete remission; CRp, complete remission without full platelet recovery; CRi, complete remission with incomplete hematologic recovery; ECOG PS, Eastern Cooperative Oncology Group Performance Score; ELN, European LeukemiaNet; HMA, hypomethylating agent; LDAC, low-dose cytarabine; MLFS, morphologic leukemia-free state; ORR, overall response rate; VEN, Venetoclax.

Methods: *Treatment*- Several factors were incorporated to mitigate the risk of hematologic toxicity and tumor lysis syndrome: 1) a 7-day VEN prephase incorporating dose ramp-up to achieve steady state prior to commencing chemotherapy; 2) dose escalation commenced at VEN 50mg (Cohort A), 100mg (B), 200mg (C), 400mg (D) and 600mg (E); 3) during induction, staggered and attenuated (Yoon *et al*, Am J Hematol 2013) addition of cytarabine (100mg/m^2/d continuous IVI d8-12) and idarubicin (12mg/m^2 IV d9-10); 4) a treatment-free VEN phase after d14 to allow hematopoietic recovery and 5) for patients in remission, further therapy with 4 cycles of "continuation" comprising 14 days of VEN at the cohort prescribed dose and bolus cytarabine 100mg/m^2 IV (days 8-9) and idarubicin 12mg/m^2 IV (day 8). After continuation, up to 7 cycles of VEN maintenance monotherapy were permitted. Antifungal azoles were prohibited during the period of VEN exposure in cohorts A-E. *Eligibility- De novo* or secondary AML (excluding APL), age ≥65 years (unless ≥60yo with monosomal karyotype), ECOG 0-1, adequate organ function, WCC <25x10^9/L, prior therapy for MDS/AML with HMA/LDAC was permitted after a 14-day washout. The first patient was enrolled on 17JUL2016. *Dose-limiting toxicity (DLT)*- Grade 4 neutropenia or thrombocytopenia lasting >42d after starting chemotherapy unrelated to residual AML/MDS and severe marrow hypocellularity <10%; other grade 4 toxicity related to VEN. *Response*- ELN 2010 response criteria.
Results: Data cut-off date was 13FEB2018. 37 patients were enrolled with 35 evaluable for response. Table 1 summarizes baseline characteristics of each cohort. Median age was 71 years (22% ≥75 years), 43% had secondary AML and 31% prior HMA failure. Grade ≥3 adverse events (≥10% of patients) during induction were thrombocytopenia (100%), neutropenia (100%), febrile neutropenia (70%), neutropenic sepsis (24%) and atrial fibrillation (14%). One hematologic DLT was reported in Cohort E (VEN 600 mg), with persistent neutropenia and thrombocytopenia beyond day 42 in a patient with transformed myelofibrosis. Maximum tolerated dose (MTD) has not yet been reached. Early mortality was 8% and 24% at 30 and 60 days, respectively. CR/CRi rate was 25/35 (71%) (Table 1). During the venetoclax pre-phase, the median relative bone marrow blast count change was -20% (range -70.5 to +14.5%). For those who achieved CR/CRi, the median time to both neutrophil (≥0.5x10^9/L) and platelet (≥50x10^9/L) recovery during induction was 25 days from day 1 of chemotherapy. Median follow-up of survivors was 9.2 months (range 0.3-17.9 months).
Summary/Conclusion: To date, the MTD has not been reached with VEN up to 600mg in combination with 5+2 chemotherapy in fit older patients with AML. The overall CR/CRi rate is 71%. Analyses for response duration and survival are ongoing.

Acute lymphoblastic leukemia – Clinical

Background: Tisagenlecleucel, anti-CD19 CAR T-cell therapy, produces high response rates with manageable safety in pediatric r/r B-cell ALL. However, limited data indicate that adult patients (pts) with ALL are at higher risk of adverse events (AEs), including cytokine release syndrome (CRS).
Aims: Characterize the safety and efficacy of young adult (YA) pts (≥18 y) with B-cell ALL treated with tisagenlecleucel in the ELIANA (N=75 [NCT02435849]) and ENSIGN (N=29 [NCT02228096]) trials.
Methods: 84 pts were <18 y and 20 were 18-25 y. Endpoints include overall remission rate (ORR) (complete remission [CR] + CR with incomplete blood count recovery [CRi]), minimal residual disease (MRD)–negative response, duration of response (DOR), overall survival (OS), and safety.
Results: Both cohorts had a median of 3 prior lines of therapy; rates of prior stem cell transplant (55% in YA; 62% in <18 y) were similar. At the time of enrollment, median (range) bone marrow blasts in YA pts was 84% (12%-98%) and 73% (5%-99%) in pts <18 y. Median age (range) at infusion was 20 y (18-25) in YA pts and 10 y (3-17) in pts <18 y. Median dose was $3.2x10^6$ CAR-positive viable T-cells/kg (range, $0.2\text{-}5.4x10^6$ cells/kg). ORR (95% CI) was 70% (46%-88%; 14/20 pts) in YA pts *vs* 80% (70%-88%; 67/84 pts) in pts <18 y. In the YA cohort, 13 of 14 responses were MRD negative, as were 66 of 67 in the <18 y cohort. Median DOR was not reached in either group. Relapse-free survival rates at months 6 and 12 were 83% and 52%, respectively, in YA pts and 75% and 60% in pts <18 y. OS rates at months 6 and 12 were 74% and 57%, respectively, in YA pts and 89% and 76% in pts <18 y. 8 YA pts (40%) died after infusion (all >30 d): 5 from ALL, 1 infection (systemic mycosis), 1 hepatobiliary disease, and 1 unknown (consent withdrawn). 21 pts (25%) <18 y died after infusion: 17 from ALL (2 ≤30 d), 2 infections (1 HHV-6 encephalitis, 1 lower respiratory infection), 1 cerebral hemorrhage (≤30 d), and 1 septic embolic stroke (≤30 d). The rate of grade 3/4 AEs within 8 weeks of infusion in YA pts was 90% *vs* 81% in pts <18 y; the rate of grade 3/4 AEs >8 weeks after infusion in YA pts was 41% *vs* 46% in pts <18 y. The rate of any-grade CRS was 90% in YA pts *vs* 79% in pts <18 y; rates of grade ≥3 CRS were similar (45% *vs* 44%). Median time to CRS onset was 3 d in both cohorts; median duration was 9 d in YA pts *vs* 8 d in pts <18 y. In pts with CRS, rates of intubation and dialysis were 28% and 22%, respectively, in YA pts *vs* 17% and 11% in pts <18 y. 44% of YA pts were admitted to the intensive care unit (ICU) *vs* 59% of pts <18 y; median duration (range) of ICU stay in YA pts was 16 d (3-27 d) *vs* 7 d (1-34 d) in pts <18 y. Of YA pts with CRS, 39% received anti-cytokine therapy, 17% received up to 3 doses of tocilizumab, and 28% received corticosteroids *vs* 42%, 5%, and 21%, respectively, in pts <18 y. Infection concurrent with CRS occurred in 33% of YA *vs* 18% of pts <18 y; no CRS-related fatalities or cerebral edema occurred in either cohort. Other grade ≥3 AEs of special interest included neurological events (YA, 15%; <18 y, 10%), prolonged cytopenias (30%; 29%), infections (35%; 16%), febrile neutropenia (20%; 38%), and tumor lysis syndrome (5%; 2%).

Table 1.

Table. Grade 3 and 4 AEs of Special Interest, Regardless of Relationship to Tisagenlecleucel Occurring ≤ 8 Weeks After Infusion

AEs of Special Interest, %	<18 Years (n = 84)		YA (≥18 Years) (n = 20)	
	Grade 3	Grade 4	Grade 3	Grade 4
Cytokine release syndrome*	21	23	15	30
Neurological events	10	0	15	0
Febrile neutropenia	36	2	20	0
Cytopenias not resolved by day 28	15	14	10	20
Infections	14	2	30	5
Tumor lysis syndrome	2	0	5	0

* CRS was graded using the Penn CRS grading scale.

Summary/Conclusion: Although sample size is small, tisagenlecleucel appears to induce high rate of durable responses in YA pts, with a safety and efficacy profile consistent with that in pts <18 y. No fatality related to CRS and no cerebral edema were reported. Tisagenlecleucel offers a potential new option for young adult pts with r/r B-ALL.

Background: ALL is heterogeneous in terms of genetics, clinical presentation and therapy response. Risk stratification, based on diagnostic features and early treatment response, has improved outcome. However, current algorithms use risk factors as binary variables which reduces statistical power and fails to account for biological heterogeneity. Moreover, using thresholds results in fixed group sizes which reduces options when designing clinical trials.
Aims: To develop a prognostic index (PI) which (a) integrates genetic, clinical and response data; (b) utilises continuous data; and (c) can be used to define clinically meaningful risk groups.
Methods: The discovery cohort comprised 2,542 UKALL203 patients who achieved a morphological remission. The validation cohort comprised 2,470 patients treated on the COALL-03, DCOG-ALL10 or NOPHO-ALL2008 protocols. Patients were followed-up for a median of 7/6 years (discovery/validation). MRD values, $>1x10^{-5}$, were log transformed with undetectable MRD assigned a value one log below the minimum detection level. Age, MRD and WCC were examined as continuous variables. Good risk genetics (GR-GEN) comprised *ETV6-RUNX1* and high hyperdiploidy; while high risk abnormalities (HR-GEN) were *KMT2A*, haploidy, low hypodiploidy, *TCF3-HLF* and iAMP21.
Results: Univariate Cox regression analysis of the discovery cohort revealed 10 risk factors for EFS: sex, age, Down syndrome, WCC, CNS disease, T-ALL, MRD, slow early response, GR-GEN and HR-GEN (each p≤0.002). Boot-strapped multivariate modelling identified a prognostic model com-

prising MRD, WCC, GR-GEN and HR-GEN. The fit of this model was not improved by adding age nor diminshed in T-ALL. The robustness of the model was assessed using cross-validation techniques and Harrell's C index was 0.73. Coefficients were used to construct a linear model allowing patient specific PI scores to be calculated (Fig1); revealing a distribution with a mean and SD of -1.62 (0.80). The risk of relapse (RR) correlated with the PI and patients with a PI>0 had a RR>35%. Each unit increase in PI more than doubled RR: hazard ratio 2.74 (95% CI 2.38-3.16), p<0.001. The PI also correlated with time to relapse (p<0.0001). A variety of formal validation methods were used to evaluate the model. The distribution of PI in the validation cohort was similar (mean -1.59, SD 0.79), as was the hazard ratio and C-index (2.18 (1.89-2.51), p<0.001 and 0.69). The validation tests demonstrated that the model accurately predicted outcome for the vast majority of patients. Fig 2 compares the EFS in the two cohorts after segregation into risk groups comprising 50%, 40% and 10% patients. Thus, the model can discriminate risk groups in patient cohorts treated differently. Moreover, it demonstrates the flexibility of a numeric PI to define clinically relevant risk groups of any given size. To compare the prediction accuracy of the PI with traditionally defined risk groups, we assessed the area under the curve (AUC) for each clinical trial. For all 4 trials, the PI was better (higher AUC) at predicting EFS compared with standard risk groups: ALL2003 0.72 v 0.61, p<0.001; NOPHO-ALL2008 0.71 v 0.66, p=0.005; COALL-03 0.71 v 0.51, p<0.001; DOCG-ALL10 0.67 v 0.58, p=0.001.

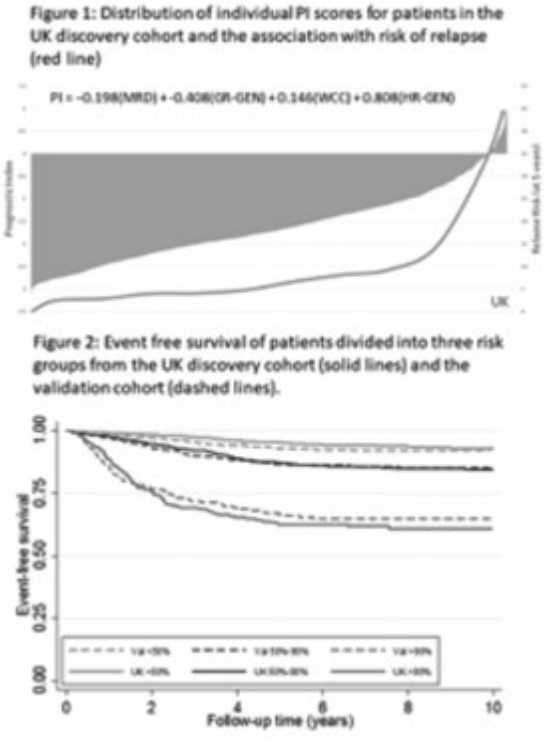

Figure 1.

Summary/Conclusion: We have developed and validated a novel PI for predicting outcome in paediatric ALL. The model integrates multiple risk factors using continuous data enabling individual numeric risk scores to be calculated. This model provides an accurate method for predicting outcome and allows greater flexibility for defining treatment group sizes.

Background: Impressive improvements of survival rates in pediatric acute lymphoblastic leukemia (ALL) have been achieved during the last decades, but a significant proportion of patients still suffers from relapse and therapy-related toxicities. Further improvement of therapy can be achieved by better personalized adjustment of treatment to the risk of relapse.
Aims: While most research activities on genetic prognostic factors have focused on somatic features, relatively little is known on hereditary contributions to treatment response and outcome in pediatric ALL. Therefore, we conducted a genome-wide association study (GWAS) of relapse in B cell precursor (BCP) ALL.
Methods: Our study included 1152 patients from AIEOP-BFM ALL 2000 (Schrappe *et al.* Blood 2011). On this trial, patients were stratified into three risk groups, mainly by minimal residual disease (MRD) analyses. Treatment employed standard drugs. Complete remission (CR) was defined as the absence of physical signs of leukemia or detectable leukemia cells on blood smears, <5% leukemia blast cells present in the bone marrow, and normal cerebrospinal fluid (CSF). The diagnosis of relapse was only made after CR has been achieved before and was defined as isolated bone marrow, combined bone marrow, CNS or testicular relapse. Of the 1152 patients included, 145 relapsed (cases) and 1007 patients remained in long-term CR (controls). DNA isolated from remission samples was genotyped by Illumina Human1M-Duo BeadChips containing 1.048.711 single SNV markers. For GWAS analyses gPLINK v2.050, PLINK v.1.09 and RStatistics v3.3.1 were used. Replication analyses were conducted in a cohort of 73 relapsed and 615 non-relapsed patients treated on trial AIEOP-BFM ALL 2009.
Results: After quality control assessment, the analysis of the initial cohort included 751.432 SNPs among 130 relapsed compared to 889 control patients. Twenty candidate SNVs demonstrating promising associations with risk of relapse were selected for replication analysis, including intronic SNVs in the Ankyrin repeat and SOCS box protein 3 (*ASB3*, rs1549749, P=8.593×10^{-7}, odds ratio, OR, 2.48) and the inositol polyphosphate multikinase (*IPMK*, rs7919168, P=1.266×10^{-5}, OR 2.06). One additional SNV in *ASB3* and six additional SNVs in *IPMK* were in linkage disequilibrium with rs1549749 and rs7919168 and demonstrated significant levels of P ≤1.7×10^{-5}. Replication analyses in an independent cohort from AIEOP-BFM ALL 2009 confirmed the initial observations for risk of relapse conferred by rs1549749 and rs7919168 and - in combined analysis of the initial and replication cohort - revealed genome-wide significance (rs1549749, P=4.98×10^{-8} OR=2.09; rs7919168, P=1.3×10^{-8} OR=3.13). In further analysis of the initial cohort from AIEOP-BFM ALL 2000, rs1549749 and rs7919168 risk alleles were associated with a significantly lower 5-year-event-free survival (EFS) compared to wildtype (0.75±0.03 *vs* 0.9±0.01, P<0.0001; 0.79±0.09 *vs* 0.99±0.01, P=0.008). Multivariate Cox analyses of the above *ASB3* and *IPMK* SNVs demonstrated independence of the observed relapse risk associations (hazard ratio rs1549749: 1.55, 95% CI 1.15-2.10; hazard ratio rs7919168: 2.10, 95% CI 1.48-2.97).
Summary/Conclusion: We identified genome-wide significant associations of *ASB3* and *IPMK* germline variations with risk of relapse in BCP ALL patients treated on BFM protocols for pediatric ALL. These results suggest that germline genetic variation influences effectiveness of chemotherapy in pediatric ALL and represent an important additional step in defining the hereditary contribution to the risk of relapse in pediatric ALL.

[1]University Hospital Saint-Louis, AP-HP, [2]University Paris Diderot, Paris, [3]CH, Versailles, France, [4]HUG, Geneve, Switzerland, [5]CHU Lyon Sud, Lyon, France, [6]UC, Louvain, Belgium, [7]CHU, Nantes, [8]IUCT, Toulouse, [9]CHRU, Lille, France, [10]Oncology Institute, Bellizona, Switzerland, [11]University Hospital Henri Mondor, AP-HP, Creteil, [12]CHU, Caen, [13]IGR, Villejuif, [14]CH, Roubaix, [15]GRAALL, Lyon, [16]CHU, Angers, France

Background: Ig/TCR-based minimal residual disease (MRD) is a faithful marker of response to therapy and the strongest predictor of relapse in Ph-negative ALL. In adults with Ph+ ALL, MRD is commonly monitored by

BCR-ABL1 transcript quantification although its prognostic significance is less clear. It has been shown that *BCR-ABL1* rearrangement may be found in non-lymphoblastic cells in some of these patients.
Aims: We aimed to study the biological significance of BCR-ABL1 MRD in Ph+ ALL.
Methods: The study includes 57 adults with *de novo* Ph+ ALL enrolled in the ongoing GRAAPH-2014 trial. Bone marrow (BM) and peripheral blood (PB) follow-up (FU) samples were collected after each treatment cycle (first 4 time-points [TPs]) and during FU. MRD monitoring was performed by quantification of both *BCR-ABL1* transcripts and Ig/TCR clonal rearrangements. *BCR-ABL1* major molecular response (MMR) was defined as *BCR-ABL1/ABL1* ratio <0.1%. We sequenced genomic fusions using capture and NGS of *BCR* and *ABL1* introns and designed breakpoint-specific PCR systems to quantify BCR-ABL1 genomic fusion with the same methods as for Ig/TCR MRD. MRD levels between markers were compared using Spearman rank correlation (r). For a given FU sample, results were considered discrepant if more than one $\log_{10}$ difference or positivity/negativity discordance, taking account markers sensitivity.
Results: Quantification of genomic BCR-ABL1 and Ig/TCR MRD levels on 72 samples from 10 patients revealed poor correlation (r=0.51). This was related to discordant results from 2 patients who had repeatedly positive BCR-ABL1 samples while Ig/TCR MRD was undetectable, suggesting those patients had lymphoblast clearance but persistent clonal BCR-ABL1 hematopoiesis. By contrast, genomic and transcript BCR-ABL1 levels on the same FU samples were well correlated (r=0.80), showing that there was no disparity related to BCR-ABL1 transcriptional modulation. This prompted us to extend our study to the whole cohort by comparing *BCR-ABL1* transcript and Ig/TCR MRD levels. We obtained data for 360 FU samples (BM=152; PB=208). Patients with at least 2 samples with discrepant *BCR-ABL1* and Ig/TCR MRD levels were considered having divergent kinetics in relation with BCR-ABL1 clonal hematopoiesis. They represented a group of 27 patients (47%). As compared with remaining patients, this group showed unbalanced M/F sex ratio (2.9 *vs* 0.8, p=0.03), enrichment in major *BCR-ABL1* breakpoint (M-bcr, 33% *vs* 7%, p=0.02) and less frequent *IKZF1* intragenic deletions (48% *vs* 77%, p=0.03). As expected, those patients had less *BCR-ABL1* MMR at TP2 in BM (54% *vs* 100%, p<0.001) and PB (39% *vs* 96%, p<0.001). By contrast, the prevalence of poor early Ig/TCR MRD was similar in the two groups (35% and 29%). At later TPs, patients with divergent kinetics mostly reached MMR in BM but maintained relatively high *BCR-ABL1* levels in PB (MMR rate at TP4, 79% and 47% in BM and PB respectively).
Summary/Conclusion: A subgroup of adults with Ph+ ALL displays persistence of BCR-ABL1 detection during treatment which is not linked to poor lymphoblast clearance but to clonal hematopoiesis. This entity resembles CML, although mostly related to m-bcr breakpoint and without evidence of myeloproliferation. Its prognostic relevance will be evaluated in our ongoing GRAAPH-2014 trial. Yet, these observations have important implications as non-lymphoblastic persistent BCR-ABL1 hematopoiesis may not necessarily need treatment intensification nor indicate lymphoid antigen-directed therapies.

OUTCOMES OF PATIENTS WITH RELAPSED/REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA TREATED WITH PRIOR BLINATUMOMAB IN ZUMA-3, A STUDY OF KTE-C19, AN ANTI-CD19 CHIMERIC ANTIGEN RECEPTOR (CAR) T CELL THERAPY

O.O. Oluwole[1,*], B.D. Shah[2], M.R. Baer[3], M.R. Bishop[4], H. Holmes[5], G.J. Schiller[6], W. Donnellan[7], K.M. O'Dwyer[8], A. Mardiros[9], J.M. Rossi[9], T. Shen[9], A. Xue[9], R.K. Jain[9], R. Vezan[9], W.G. Wierda[10]

[1]Vanderbilt-Ingram Cancer Center, Nashville, [2]Moffitt Cancer Center, Tampa, [3]University of Maryland, Greenebaum Comprehensive Cancer Center, Baltimore, [4]The University of Chicago Medicine, Chicago, [5]Texas Oncology-Baylor Charles A. Sammons Cancer Center, Dallas, [6]David Geffen School of Medicine at UCLA, Los Angeles, [7]Sarah Cannon Research Institute, Nashville, [8]University of Rochester, Rochester, [9]Kite, a Gilead company, Santa Monica, [10]The University of Texas MD Anderson Cancer Center, Houston, United States

Background: KTE-C19 showed promising efficacy (71% complete response [CR] or CR with incomplete hematologic recovery [CRi]) and manageable safety for patients with relapsed/refractory acute lymphoblastic leukemia (R/R ALL) in Phase 1 of ZUMA-3 (Shah ASH 2017; NCT02614066). Blinatumomab (blin), a CD19/CD3 bispecific T cell engager, is US FDA-approved for R/R ALL. The impact of prior blin on KTE-C19 efficacy is unknown.
Aims: To report responses to KTE-C19 in patients who received prior blin.
Methods: All patients provided written informed consent. Eligible patients were aged ≥18 years with R/R ALL (Ph+ allowed), ≥5% bone marrow blasts (documented CD19+), and ECOG 0-1. Patients received 2, 1, or 0.5×10^6 CAR T cells/kg after low-dose conditioning chemotherapy. Patients who received the 2×10^6 dose could not have prior blin. Outcomes assessed included efficacy, safety, product characteristics, and levels of CAR T cells and cytokines in blood.
Results: As of July 31, 2017, 29 patients were evaluable for safety, 24 for efficacy. A total of 6, 14, and 9 safety-evaluable patients received 2, 1, and 0.5×10^6 CAR T cells/kg, respectively. Patients with (n=11) *vs* without (n=18) prior blin had worse performance status (ECOG 0: 27% *vs* 44%) and were more likely to be R/R to ≥2nd-line therapy (55% *vs* 28%). With ≥8 weeks of follow-up, 63% *vs* 75% of patients with *vs* without prior blin had CR or CRi, respectively. Overall, 88% (21/24) had minimal residual disease-negative remission (7/8 with *vs* 14/16 without prior blin). Of patients with *vs* without prior blin, 27% *vs* 28% had Grade ≥3 cytokine release syndrome and 36% *vs* 61% had Grade ≥3 neurologic events. KTE-C19 was manufactured successfully in both groups, with similar product characteristics (eg, CD4/CD8 ratio, % transduction). Patients with *vs* without prior blin had similar proportions of naïve (43% *vs* 36%) and effector memory (19% *vs* 20%) T cells. Postinfusion CAR T expansion was observed regardless of prior blin; peak CAR T cell levels occurred between Days 7 and 14 for both groups.
Summary/Conclusion: While potentially confounded by multiple factors, these data demonstrate that prior blin did not preclude manufacturing of efficacious products. KTE-C19 continues to show promising efficacy and manageable safety in patients with R/R CD19+ ALL independent of prior blin.

Genetics and epigenetics of CLL

S1570

LINKING ABERRANT CHROMATIN FEATURES IN CHRONIC LYMPHOCYTIC LEUKEMIA TO DEREGULATED TRANSCRIPTION FACTOR NETWORKS

D. Mertens[1,2,*], J.-P. Mallm[3], M. Iskar[4], N. Ishaque[5], S. Kugler[1], H. Döhner[1], P. Lichter[4], S. Stilgenbauer[1], K. Rippe[3]

[1]Internal Medicine III, University Ulm, Ulm, [2]Mechanisms of Leukemogenesis, [3]Chromatin Networks, [4]Molecular Genetics, [5]Theoretical Bioinformatics, DKFZ German Cancer Center, Heidelberg, Germany

Background: Though numerous recurrent epigenetic mutations have been identified in chronic lymphocytic leukemia (CLL), their role in the molecular and clinical pathomechanism is only partly understood.
Aims: To provide the missing links between the cancer epigenotype and phenotype, we profiled the chromatin landscape and the transcriptome in primary peripheral blood cells of 19 CD19 sorted samples of untreated chronic lymphocytic leukemia (CLL) patients in comparison to 9 pools of non-malignant CD19-sorted B cells from 65 age-matched healthy donors.
Methods: We characterized DNA methylation by whole genome bisulfite sequencing, the major histone modification (H3K4me1, H3K4me3, H3K9me3, H3K9ac, H3K27me3, H3K27ac and H3K36me3) by ChIP-seq, nucleosome occupancy from high coverage H3 ChIP-seq and open chromatin sites were identified by the assay for transposase-accessible chromatin (ATAC-seq) in both bulk and single cells. In addition, RNA transcription was analyzed by strand-specific RNA-seq of both long and short RNAs.
Results: Remarkably, the CLL DNA methylome contains a large genome fraction of ~50% partially methylated domains in comparison to non-malignant B cells (<1 %). Auto- and cross-correlation of histone modifications showed changes for the active promoter mark H3K4me3 and for the repressive H3K27me3 modification, leading to terminal inactivation of poised promoters and activation of alternative transcriptional start sites in CLL. Most significant changes were observed at enhancers, and 256/279 (92%) of enhancers with changed H3K27ac signal that overlapped with partially methylated domains were activated. ATACseq uncovered 24400 differentially open loci at promoters, enhancers and repressed regions in CLL cells. Single cell ATACseq correlations of loci were used to infer spatial enhancer-promoter contacts and their local enrichment. In total 17,122 promoter-enhancer pairs were identified, with 11,585 promoters being assigned to different enhancers in CLL and non-malignant B cells. Of these re-wired promoters 921 and 438 were linked to genes down- and upregulated in CLL, respectively. We selected the most relevant transcription factors (TFs) that displayed differential binding in two or more of the chromatin readouts (Figure). The aberrant regulatory epigenetic signals were detected at 83% of the transcriptionally deregulated of genes in CLL, explaining the large majority of transcriptional dysregulation in CLL. The connections present in our B-cell gene regulatory network together with direct protein-protein interactions listed in the String database defined TF regulatory modules and provided links to chromatin modifiers. A gene set enrichment analysis of targets of these TFs retrieved NFkB and BCR signaling as the top hits. The network also includes the induction of the TCF4 in CLL via a large-scale enhancer activation and its linkage to expression of the anti-apototic BCL2 factor.

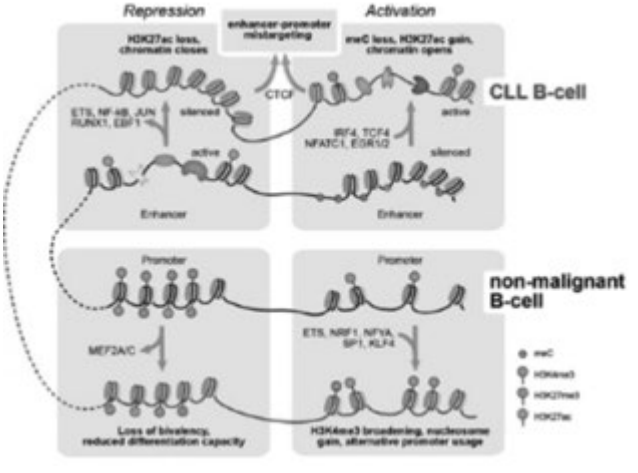

Figure 1.

Summary/Conclusion: The deregulated TF network identified here rationalizes how the epigenetic pathophenotype of CLL is linked to changes in TF activity. Understanding the transcriptional dysregulation of the molecular targets of novel therapies will help to personalize treatment, reduce serious adverse events and thereby optimize outcome of CLL patients.

Cohen[6], A. Steele[1], R. Rosenquist[7], A. Collins[8], A. Pettitt[9], P. Hillmen[6], C. Plass[10], A. Schuh[3], D. Catovsky[5], D. Oscier[4], C. Oakes[11]

[1]Cancer Sciences Unit, Faculty of Medicine, [24]Human Development and Health, University of Southampton, Southampton, [3]Oxford National Institute for Health Research Biomedical Research Centre and Department of Oncology, University of Oxford, Oxford, [4]Department of Pathology, Royal Bournemouth Hospital, Bournemouth, [5]The Institute of Cancer Research, The Institute of Cancer Research, Sutton, [6]Leeds Institute of Clinical Trials Research, University of Leeds, Leeds, United Kingdom, [7]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden, [8]Human Development and Health, University of Southampton, Southampton, [9]Department of Molecular and Clinical Cancer Medicine, University of Liverpool, Liverpool, United Kingdom, [10]Division of Epigenomics and Cancer Risk Factors, The German Cancer Research Center, Heidelberg, Germany, [11]Division of Hematology, The Ohio State University, Columbus, United States

Background: Even in the era of the targeted therapies, there remains clinical value in exploring the impact of disease characteristics in chemo-immunotherapy (CIT) trials, namely to identify features that contribute most to long-term outcomes, thereby pinpointing patients destined to benefit from these therapies. One such feature is the CLL DNA methylome, that recapitulates normal B cell maturation, with IGHV mutated (M-CLL) and unmutated CLL (U-CLL) retaining an imprint of the DNA methylation signature of memory (m-CLL) and naive B cells (n-CLL), respectively, with a third intermediate epigenetic subgroup (i-CLL) with borderline mutation status. The pyrosequencing analysis of 5 CpG sites can divide CLL into these three subgroups, each with different clinico-biological features.
Aims: To validate the clinical utility of the epigenetic subgroups in patients entering clinical trials.
Methods: We classified 605 treatment-naïve patients randomized to one chemotherapy (CLL4) and two CIT (ARCTIC and ADMIRE) trials, into the three epigenetic subgroups using pyrosequencing and confirmatory Infinium HumanMethylation450 analysis (n=60, 96% concordance between technologies).

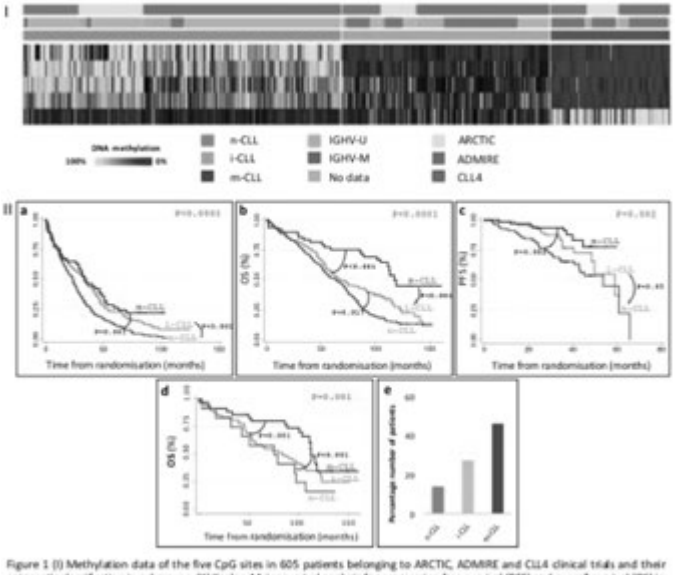

Figure 1 (i) Methylation data of the five CpG sites in 605 patients belonging to ARCTIC, ADMIRE and CLL4 clinical trials and their epigenetic classification in subgroups. (ii) Kaplan-Meier survival analysis for progression free survival (PFS) and overall survival (OS) in CLL4 (a and b) trial and PFS in combined ARCTIC and ADMIRE trials (c) for all patients. Kaplan-Meier survival analysis for OS in IGHV-M patients belonging to the CLL4 trial (d). Percentage long-term survivors (>10 years OS) in each of the three epigenetic subgroup (e).

Figure 1.

Results: We identified n-, i- and m-CLL in 49.5% (n=298), 32.0% (n=195) and 18.5% (n=112) of our patients, respectively (**Fig1I**). Fewer m-CLL patients were identified in our study compared to published data, reflecting the progressive nature of our cohort, with 80% (n=245/305, P<0.001) of U-CLL cases exhibited the n-CLL signature (i-CLL: 17% and m-CLL: 3%). For M-CLL cases 9%, 50% and 41% exhibited the n-, i- and m-CLL epigenetic signature, respectively. In 359 CLL4 patients, n-, i- and m-CLL patients exhibited a median PFS of 23, 35 and 33, and OS of 63, 66 and 106 months, respectively (**Fig1IIa and b**). n-CLL showed significantly shorter PFS than i-CLL (HR 0.64, p<0.001) and m-CLL (HR 0.52, p<0.001), and had the shortest OS, again compared to i-CLL (HR 0.73, p=0.01) and m-CLL (HR 0.33, p<0.001). The epigenetic signature was associated with long-term survival (>10 years OS), with n-CLL accounting for only 14% of this subgroup (P<0.001, **FigIIe**). In IGHV-M patients, the m-CLL subgroup showed 104 months of median OS compared to 79 and 84 months in n- and i-CLL subgroups (**FigIId**). Multivariate Cox proportional analysis, controlling for confounding variables (inc. clinical features, IGHV status, *TP53*, *NOTCH1* and *SF3B1*) in 278 patients showed that m-CLL was an independent prognostic factor for OS (HR 0.46, p<0.01), but not PFS. In univariate analysis, in 247 patients randomized to ARCTIC and ADMIRE, the i- (HR:0.57, p=0.05) and m-CLL (HR:0.3, p=0.002) subgroups displayed longer PFS (**Fig1IIc**). In a multivariate model, including *TP53* lesions and IGHV status (239 patients), the m-CLL subgroup retained its independent prognostic significance (HR:0.25, p<0.001).

Summary/Conclusion: In conclusion, we report the first analysis of the clinical utility of epigenetic subgroup signatures in patients entered into first-line chemotherapy and CIT trials and identified m-CLL as an independent marker of survival in both our CLL4 and ARCTIC/ADMIRE cohorts. This provides important evidence that DNA methylation analysis may aid in the identification of patients destined to demonstrate durable remissions when treated with these agents.

Background: Chronic lymphocytic leukemia (CLL) is characterized by proliferation and accumulation of malignant B cells, where this process is associated with constitutively activated B cell receptor (BCR) signaling, and interference with BCR signaling provides therapeutic benefit. Specifically, the Bruton's Tyrosine Kinase (BTK) inhibitor ibrutinib prevents BTK tyrosine phosphorylation and thereby interferes with the pathway. It has shown high clinical response rates in patients with relapsed and refractory CLL, including patients with adverse cytogenetic profiles. Despite high responses achieved by ibrutinib, it has important limitations such as inducing CLL cell redistribution from protected niches to the periphery, and the clinical response to ibrutinib is slow and often incomplete. Further, there is no evidence that a cure can be achieved, even among patients that tolerate long-term treatment with ibrutinib, a considerable percentage develops drug resistance, *BTK* independent disease progression, or Richter's transformation, indicating drug synergies with ibrutinib may increase prognosis. Recent studies have explored combined use of ibrutinib with inhibitors for the proteasome (carfilzomib), BCL2i (venetoclax), and HDAC (abexinostat) in preclinical models, which has shown promising initial results. However, these approaches were largely empirical, and do not have systamatic rational.

Aims: We charted the ibrutinib-induced chromatin regulatory landscape of CLL, and in parallel mapped targetable pathways for synergistic combination therapies that could potentially improve disease control. Peripheral blood from 24 fully characterized CLL cases were collected before and during therapy with ibrutinib. Chromatin accessibility was measured by ATAC-seq to gather the genome-wide regulatory landscape, and *ex vivo* chemosensitivity to >140 drugs on paired CLL samples was measured using Pharmacoscopy, a translatable method for *ex vivo* single-cell drug cytotoxicity profiling in primary samples (Snijder *et al.* Lancet Haematology, 2017; NCT03096821).

Methods: We bioinformatically integrated these datasets, establishing a comprehensive picture of the cellular responses to ibrutinib, and to prioritize targets, we performed secondary differential synergy screening of 21 drugs in combination with Ibrutinib in 8 CLL patient samples taken prior to clinical Ibrutinib treatment, with the goal to visualize changes in the targeted sensitivity of key drugs with and without Ibrutinib treatment.

Results: ATACseq identified increases in chromatin accessibility and chemosensitivity in proteasome, inflammatory NF- B/TNF signaling, CoA biosynthesis, PI3K/Akt, pathways, along with changes affecting genes such as FOXO3 and I Ba, and both the ex vivo drug testing of samples from patients after clinical ibrutinb and *ex vivo* synergy screening revealed that ibrutinib treatment *in vivo* and *in vitro* sensitizes CLL cells to compounds such as the proteasome inhibitor bortezomib, the JAK inhibitor ruxolitinib, the bisphosphate zoledronate, and the aurora kinase inhibitor ZM447439.

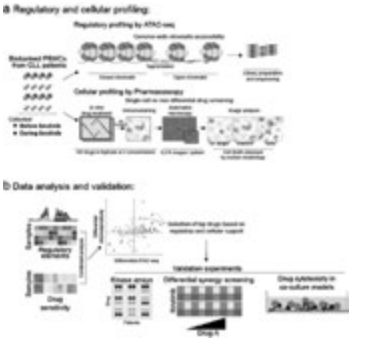

Figure 1.

Summary/Conclusion: Our results show that synergistic combination and informatics-integration of chromatin profiling with functional drug screening is a powerful tool to identify targetable pathways in CLL. This approach may be useful for designing personalized therapies as well as providing planning for clinical studies. Our approach is directly transferable to other leukemia where malignant cells can be obtained for chromatin profiling and drug sensitivity analysis, thus providing a widely applicable tool for the rational development of combination therapies.

S1573

GROWTH DYNAMICS IN NATURALLY PROGRESSING CHRONIC LYMPHOCYTIC LEUKEMIA

Background: Exome-wide characterization of somatic mutations in large cohorts of chronic lymphocytic leukemia (CLL) patients provided a comprehensive catalogue of alterations that putatively drive the disease. But how the genomic features of a patient's CLL cells relate to individual disease kinetics remains poorly understood.

Aims: We leveraged the indolent growth dynamics of CLL to perform a time-resolved analysis of growth rates and genomic patterns of leukemia clones from 113 patients, spanning decades-long disease courses.

Methods: For high-resolution characterization we selected 21 CLL patients who progressed to need for treatment, through the CLL Research Consortium, housed at UCSD. We performed whole exome sequencing on 2-6 serial

samples spanning the period from diagnosis to start of chemoimmunotherapy. Using pre-treatment measurements of white blood cell counts (WBC), we determined growth kinetics over time. We validated findings in a cohort of pre-treatment samples from 92 CLL patients enrolled at the Dana-Farber Cancer Institute (DFCI, Boston, MA). For whole-exome sequencing (WES), we used Broad Institute sequencing and analysis protocols. Cancer cell fractions of mutations were estimated using the ABSOLUTE algorithm to calculate the purity, ploidy, and absolute DNA copy-numbers of each sample. To infer the clonal structure in serial samples, we employed a multi-sample phylogeny and clustering analysis tool PhylogicNDT. Growth rates per subclone were estimated based on a Monte Carlo Markov Chain algorithm integrating the uncertainty of the cluster assignment, given the proposed phylogeny and WBC measurements. Reference lists for SNVs and InDels in known putative CLL driver genes as well as for recurrent CNAs were concatenated based on previous sequencing studies of large CLL cohorts.

Results: We found that CLL commonly demonstrates not only exponential expansion but also logistic growth, which is sigmoidal and includes stabilization at a certain steady state level. In patients, whose serial samples underwent whole-exome sequencing, we found that dynamic changes in the CLL disease course were shaped by the activity of genetic events that were already present in earliest indolent stages. Each growth pattern was associated with marked differences in genetic composition, pace of disease progression and extent of clonal evolution. Finally, using an integrative analysis of somatic mutations and growth rates, we quantified the growth advantage putative CLL drivers confer *in vivo*. Accelerated growth of subclones was strongly enriched for presence of well-established statistically identified CLL drivers, for which we could also directly quantify the impact of specific mutations, such as second hits in the major tumor suppressor genes *TP53* and *ATM*.

Summary/Conclusion: By integrating information on tumor growth and genetic evolution information, we observed complex patterns even during the pre-treatment period, with various growth behavior and expansion rates amongst subclones over time. Our computational framework enabled us to assess the degree of growth acceleration of genetically defined subclones over their parental clones. This analysis provides clear evidence for the growth-accelerating role and potential synergies of subclonal driver mutations, while demonstrating the frequent existence of growth-neutral subclones that did not contain drivers and likely represent genetic drift. Our real-life *in vivo* data thus provide a conceptual framework for understanding the growth trajectories of individual populations of CLL cells.

S1574

GENOMIC ALTERATIONS IN HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA FREQUENTLY AFFECT CELL CYCLE KEY REGULATORS AND NOTCH1 REGULATED TRANSCRIPTION

Background: Beyond *TP53*, no genetic alteration has so far clearly been linked with the pathogenesis of primary high-risk or refractory chronic lymphocytic leukemia (CLL). TP53 dysfunction and defects in other DNA-damage response systems such as ATM lead to chromosomal instability with secondary events not necessarily associated with adverse prognosis. This constitutes the challenge, to differentiate between passenger alterations without survival advantage and driver alterations.

Aims: We aimed to identify pivotal genomic alterations contributing to high-risk CLL biology beyond *TP53* aberrations.

Methods: We performed high-resolution SNP-array profiling and targeted sequencing (*NOTCH1* and *SF3B1* among other candidates with potential functional relevance) on 75 relapsed/refractory CLL cases including 18 cases without TP53 dysfunction. Samples were derived from the CLL2O trial of the German / French CLL Study Groups (GCLLSG/FCLLSG). Our cohort was extended by 71 treatment-naïve *TP53*-deficient primary high-risk cases enrolled on the CLL2O trial or the CLL8 or CLL11 trial of the GCLLSG. All samples were CD19 tumor cell enriched. The GISTIC 2.0 algorithm was used to identify significantly enriched copy number alterations (CNAs). Expression of NOTCH1 target genes was quantified by TaqMan-probe-based quantitative PCR.

Results: Increased genomic complexity was a hallmark of relapsed/refractory and treatment-naïve high-risk CLL, and was associated with TP53 and ATM dysfunction. In relapsed/refractory cases previously exposed to the selective pressure of chemo(immuno)therapy, only gain(8)(q24.21) and del(9)(p21.3) were found particularly enriched beyond CNAs routinely assessed in CLL (17% and 11%, respectively). Both of these copy number alterations affected key regulators of cell cycle progression, namely *c-MYC* and *CDKN2A/B*. Gains in 8q24.21 were either focal gains in a *c-MYC* enhancer region or larger gains directly affecting the *c-MYC* locus, but only the latter type was highly enriched in relapsed/refractory CLL. Loss of *CDKN2A/B*, which never occurred in standard-risk CLL cases at treatment initiation, was found frequently to co-occur with gain of *c-MYC*. In this combination it was likely associated with Richter transformation, whereas monoallelic loss of *CDKN2A* in the absence of *c-MYC* gain was probably not. Mutations in *SF3B1* (23%) and *NOTCH1* (23%) were found enriched in high-risk CLL with a comparable distribution between relapsed/refractory and treatment-naïve cases. In addition to the high frequency of activating *NOTCH1* mutations, we found recurrent genetic alterations in *SPEN* (4% mutated), *RBPJ* (8% deleted) and *SNW1* (8% deleted), all affecting a protein complex that represses transcription of NOTCH1 target genes. We investigated the functional impact of these alterations on *HES1*, *DTX1* and *c-MYC* gene transcription. De-repression of these NOTCH1 target genes was particularly observed with *SPEN* mutations, but our results also suggested functional impact of *RBPJ* loss.

Summary/Conclusion: In summary, we show that highly complex genomic aberrations are a hallmark of high-risk CLL with *TP53* and *ATM* alteration. We provide a registry of significantly enriched CNAs, define novel recurrent CNAs and identify genomic alterations likely contributing to disease refractoriness. Enrichment of *c-MYC* gain and *CDKN2A/B* loss in relapsed/refractory CLL points to the significance of de-regulated cell cycle in high-risk biology and alterations in a protein complex repressing NOTCH1 target genes likely add to the pathogenic role of aberrant NOTCH1 signaling in CLL.

Biological insights and preclinical studies in multiple myeloma

Background: Multiple myeloma (MM) pathogenesis is characterized by a complex Darwinian evolution process where the progressive accumulation of genetic aberrations confers distinct proliferative advantage and clonal selection. Translocations between the immunoglobulin heavy chain (IGH) locus and known oncogenes, and multiple chromosome gains (Hyperdiploidy, HRD) are considered early drivers, being detectable also in premalignant stages of the disease. The IGH translocations are thought to arise from aberrant AID activity in the germinal centre; however, the pathogenesis of HRD and other aneuploidies remains unclear but are hypothesized to occur during a single failed mitotic event rather than through serial acquisitions over time.
Aims: To investigate the order of acquisition of aneuploidies in MM, we analysed whole genomes sequencing (WGS) data from 67 tumour samples, collected at different clinical time points from a cohort of 30 patients; 11 with smoldering MM (SMM) and 56 with MM at diagnosis or later stages (median of 2 samples per patients; range 1-4).
Methods: Aligned sequence files were analyzed using the published tools available at the Wellcome Trust Sanger Institute. Aneuploidies and their cancer cell fraction (CCF) was extracted by the previously published Battenberg approach.
Results: CCF analysis of the showed that 30% recurrent anueploidies were not fully clonal, suggesting their acquisition at different times during disease evolution. Ranking each event based on the distribution of its CCF, we observed that most chromosome gains in HRD, as well as amp1q, del1p and del13q occurred earlier compared to del17p, del14q and del8p. To increase the resolution of our analysis, we further developed a "molecular time" (MT) analysis of each clonal chromosome duplication greater than 1 Mb. The MT was calculated as the corrected ratio between the total number of clonal SNVs present on > 1 allele and all other clonal SNVs on one allele only. During a single allele duplication, all SNVs already present will be duplicated acquiring an allelic fraction ~66% and conversely all SNVs acquired on the non-duplicated allele (or on one of the two gained alleles after the duplication) will have an allelic fraction ~33%. In this analysis, we considered only those copy number alteration segments with a length > 1 Mb and with more than 50 clonal SNVs, extracted using the previously described dirichlet process. Integrating CCF and MT data we found that not all HRD gains were acquired at once, and in 11/18 (61%) cases the HRD karyotype was the result of multiple independent gains (MIG) acquired at different times. Interestingly we observed that in 12/18 (66%) patients the first HRD MIG event also involved other events, including amp1q that was therefore confirmed as an early event. Similarly, independent MIGs were also present in the MM (sub)clonal architecture evolution, with multiple CNAs gains lost and/or acquired during different cancer progression phases (from SMM to MM and from MM to relapsed MM). At the extreme end of the spectrum, we found 4 patients acquiring a whole genome duplication, whose occurrence only in relapsed samples suggests a potential role in relapsed/refractory stages.
Summary/Conclusion: In conclusion, in this study we described for the first time the pattern of acquisition of the HRD karyotype in MM. By integrating this analysis to the timing of acquisition of mutations, we have reconstructed the life history of the 30 MM cases, highlighting dynamic changes both spontaneous and after treatment, that will impact the way we manage the disease both in SMM and in active MM.

S1576

EXPRESSION OF PROTEINS IN CD138+ PLASMA CELLS PREDICTS PROGNOSIS IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS TREATED WITH VRD REGIMEN

I. Misiewicz-Krzeminska[1,2,3,*], L. Corchete[1,2], I. Isidro[2], T. Prieto[2], V. Gutierrez[2], E. Rojas[1,2], C. De Ramon[4], J. Martinez-Lopez[5,6,7,8], R. Garcia-Sanz[2,9,10], A. Oriol[11], J. Blade[12], J.J. Lahuerta[13], J. San Miguel[14], M.-V. Mateos[1,2,9], N. Gutierrez[1,2,9]

[1]Institute of Biomedical Research of Salamanca (IBSAL), [2]Centro de Investigacion del Cancer, Salamanca, Spain, [3]National Medicines Institute, Warsaw, Poland, [4]Hematology, University Hospital of Salamanca, Salamanca, [5]Hematology, Hospital [12] de Octubre, [6]CNIO, [7]Complutense University, [8]CIBERONC, Madrid, [9]University Hospital of Salamanca, Salamanca, Spain, [10]Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Poland, [11]Hospital Germans Trias i Pujol, [12]Hospital Clinic, Barcelona, [13]Hospital [12] de Octubre, Madrid, [14]Clínica Universidad de Navarra, Centro de Investigaciones Médicas Aplicadas (CIMA), IDISNA, CIBERONC, Pamplona, Spain

Background: The development of precision medicine requires powerful biomarkers mainly based on the mechanism of drug action to predict and improve response to treatment. Although genomic technologies have significantly increased the numbers of potential biomarkers in MM, most of them have not been subsequently validated at protein level. The low protein concentration obtained after CD138+ selection has limited the quantification of proteins in MM so far. We have recently reported the usefulness of a new technique based on capillary nanoimmunoassay (CNIA) for protein expression quantification from purified CD138+ plasma cells (PC).
Aims: To investigate the prognostic impact of the expression of proteins involved in the anti-myeloma mechanism of bortezomib (V), lenalidomide (R) and dexamethasone (D), together with the expression of cyclin D1 and D2 in a large cohort of CD138+ PC samples from MM patients treated with VRD.
Methods: Bone marrow aspirates from 213 newly diagnosed MM patients treated according to the Spanish clinical trial VRD-GEM followed by ASCT conditioned with Mel-200 *vs* BuMel, were included in the study. Plasma cells were purified by anti-CD138 magnetic microbeads using the AutoMACs separation system (purity was above 85%) and next, were stored in RLT+ buffer at -80^{0}C. Proteins were extracted by a method previously reported by our group. Total protein quantification and protein expression were analyzed by the CNIA methodology (ProteinSimple, WES™ system). Progression free survival (PFS) and overall survival (OS) were calculated for each protein. Survival curves were plotted by means of the Kaplan-Meier method and statistical significance was tested using the log-rank test. The Cutoff Finder software was used to obtain the optimal cutoff.

Table 1.

	PFS				OS

		Low	168			Low	168	

Results: After the analysis of total protein content, 194 MM samples of 213 (91%) fulfilled the quantity and quality requirements. Among the 10 proteins analyzed the expression of aiolos, cereblon, ikaros, gankyrin, proteasome activator subunit 1 (PSME1), glucocorticoid receptor (GR), exportin 1 (XPO1) and interferon regulatory factor 4 (IRF4) were detected in about 90% of MM samples. On the contrary, cyclin D1 and cyclin D2 proteins were detected in only 43% and 25% of MM samples, respectively. Regard-

ing cytogenetic risk, IRF4, PSME1 GR and XPO1 proteins were significantly upregulated in low risk MM patients, while cyclin D2 was upregulated in high risk MM (p<0.05). At the time of study, the median follow-up for survivors was 25.5 months (range, 14.1-42.1). Kaplan-Meier survival analyses showed that high levels of ikaros and gankyrin were associated with shorter PFS ($p < 0.01$ and $p < 0.05$, respectively), while high level of cereblon was associated with longer PFS ($p < 0.05$). Regarding OS, high protein levels of aiolos, cereblon, GR and XPO1 were associated with better prognosis (see table below). Interestingly, patients with high cyclin D2 protein levels had a significantly shorter PFS and OS ($p < 0.0001$), while those with high level of cyclin D1 exhibited longer OS ($p < 0.05$).

Summary/Conclusion: The expression level of proteins involved in the mechanism of action of bortezomib, lenalidomide and dexamethasone, discriminate prognosis in MM patients. High level of cyclin D2 protein identified MM patients with poor outcome. The quantification of protein expression by CNIA platform can be a useful tool for biomarker identification in the era of precision medicine.

Background: Daratumumab (DARA) is a human monoclonal IgG1 CD38-targeted antibody that has several mechanisms of action, including complement-dependent cytotoxicity, antibody-dependent cellular cytotoxicity, antibody-dependent cellular phagocytosis, modulation of CD38 enzymatic activity, and induction of apoptosis with antibody cross-linking. DARA (16 mg/kg) single-agent, phase 1/2 translational studies (SIRIUS and GEN501) revealed an additional, novel immunomodulatory mechanism of action that increased the adaptive immune response in multiple myeloma (MM). Natural killer (NK) cells were reduced in these studies, with no effect on DARA efficacy or safety (Casneuf T et al, *Blood Adv*. 2017;1[23]:2105-2114; Adams HC 3rd et al, Presented at ASH 2016; Abstract 4521). Furthermore, subsequent combination studies showed DARA promotes robust pro-adaptive immunological changes when combined with lenalidomide and dexamethasone (van de Donk NWCJ et al, Presented at ASH 2017; Abstract 3124).

Aims: To explore the ability of DARA to promote adaptive T-cell responses and immune changes in asymptomatic SMM patients (pts) in CENTAURUS (**Figure;** NCT02316106) using cytometry by time-of-flight (CyTOF®).

Methods: Intermediate and high-risk SMM pt whole-blood samples from three treatment arms were analyzed: Long (L), Intermediate (I) and Short (S) at Cycle 1 Day 1 (L, n=34; I, n=39; S, n=30) and after a minimum of one cycle of DARA (16 mg/kg intravenous) monotherapy (L at Cycle 4 Day 1, n=33; I at Cycle 4 Day 1, n=36; S at End of Treatment, n=30). Samples were stained with a metal-conjugated antibody panel and evaluated by CyTOF®. Similar cellular events were clustered into nodes using the spanning tree progression of density normalized events (SPADE) algorithm and annotated into immune-cell populations via Cytobank® software. Differences in marker intensity and cell populations within subgroups were defined by *P* values derived from Student T-tests over time and at baseline. Results were visualized by SPADE-blend trees, where each cluster was colored using a combination of *P* values related to marker intensity and cell-population size changes, and using Radviz projections to monitor complex effects.

Results: Consistent with previous studies, we observed a reduction in circulating NK cells, along with CD38 downregulation predominantly in NK cells, basophils, and $CD38^+$ regulatory T cells ($CD3^+CD4^+CD25^+CD127^-$), in all treatment arms. The proportion of T cells increased across all arms and was correlated with a higher proportion of $CD8^+$ *versus* $CD4^+$ T cells. After DARA administration, the total T-cell populations shifted towards $CD8^+$ T cells with increased production of granzyme B, a cytolytic enzyme. Prominent increases in the $CD8^+$ T-cell effector memory compartment were observed in post-DARA/on-study samples. Likely driven by differences in time of collection between treatment arms, the increase in expression of the activation marker HLA-DR was more pronounced in $CD8^+$ central memory and effector memory T cells of pts in the S arm, while granzyme B increased independent of treatment arm.

Table 1.

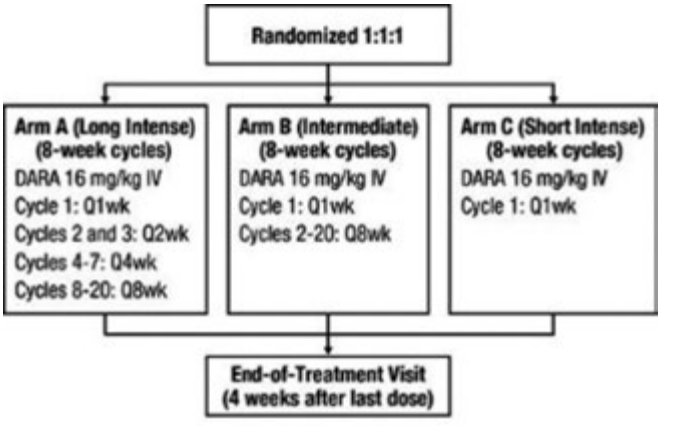

Figure. CENTAURUS Study Design.
DARA, daratumumab; IV, intravenous; Q1week, once weekly; Q2week, once every 2 weeks; Q4wk, once every 4 weeks; Q8wk, once every 8 weeks.

Summary/Conclusion: DARA administration across the three treatment arms induced clinical responses in pts and T-cell profile changes, including expansion of effector memory T cells and increased expression of activation markers. These changes are conducive to adaptive immunity. As SMM pts are relatively more immune-competent compared to MM pts, this study again demonstrates DARA's immunomodulatory activity in asymptomatic SMM which may play a part in delaying the progression to MM.

[1]Hospital Universitario de Salamanca (IBSAL). Centro de Investigación del Cáncer (IBMCC-CSIC-USAL), Salamanca, Spain, [2]Institut de Recherches Servier, Suresnes, France, [3]Novartis Institutes for Biomedical Research, Cambridge, MA, United States, [4]Novartis Institutes for Biomedical Research, Basel, Switzerland

Background: Drugs with novel mechanisms of action are essential to overcome resistance to current standards of care in MM. Recently, the BCL-2 inhibitor, venetoclax, has demonstrated to be effective in this disease, particularly in patients bearing the t(11;14) translocation. However, overexpression of MCL-1 seems to be more important in MM pathogenesis, which raises the possibility of using the new MCL-1 inhibitor, S63845, as a promising therapeutic agent for the treatment MM.

Aims: The aim of the present work was to evaluate the efficacy and mechanism of action of S63845 (MCL1i) alone and in combination with venetoclax (BCL2i) in preclinical *in vitro* and *in vivo* models of MM.

Methods: S63845 was provided by Servier. *In vitro* activity of MCL1i and BCL2i alone and in combination was evaluated on different myeloma cell lines. The combination index (CI) was calculated with Calcusyn software based on results from MTT assay. Four cell lines with different sensitivity to MCL1i (MM.1S, JJN3, KMS12-BM and NCI-H929) were chosen for the mechanistic studies. Effects on apoptosis and cell cycle were evaluated by flow cytometry. BCL-2 family protein levels were analysed by Western blot. The mechanism of action was assessed by immunoprecipitation assays. Finally, a plasmacytoma model in CB17-SCID mice and a disseminated model in BRG mice were used for *in vivo* studies.

Results: The MCL1i, S63845, showed a strong anti-tumor dose-dependent effect on nine multiple myeloma cell lines, with IC50 values at 48 hours ranging from 2.6 to 465 nM. The sensitivity to S63845 was independent of

the genetic alterations and the basal expression of the different BCL-2 family members. Although co-culture with stromal cells induced MCL-1 expression, S63845 remained active in these conditions. While no changes were observed in cell cycle, S63845 treatment induced apoptosis, triggered by mitochondrial outer membrane permeabilization. S63845 did not significantly modify the levels of MCL-1 or other BCL-2 family member in MM.1S or KMS12-BM, although immunoprecipitation assays in MM.1S, JJN3, NCI-H929 and KMS12-BM cell lines showed that S63845 impaired the MCL-1/BIM interaction. Interestingly, a compensatory increase in the BCL-2/BIM interaction in the two less sensitive cell lines tested, MM.1S and JJN3, was observed after treatment with S63845. On the other hand, the BCL-2 inhibitor displayed the opposite effect, with an impairment of the BCL-2/BIM interaction but a compensatory increase of the binding of MCL-1 to BIM. Accordingly, we hypothesized that the simultaneous inhibition of MCL-1/BIM and BCL-2/BIM interactions could result in significant synergistic induction of apoptosis. In this regard, the combination of MCL1i + BCL2i led to pronounced synergy, with CIs ranging from 0.1 to 0.4, in MM1S, JJN3, KMS-12.BM and NCI-H929 (Figure 1). Moreover, the triple combination MCL1i + BCL2i + dexamethasone showed an even stronger synergy than the double treatment of MM.1S and in JJN3 (CI<0.06 and CI<0.2, respectively). The efficacy of the triple combination MCL1i + BCL2i + dexamethasone is currently being evaluated in two murine models of human myeloma, a subcutaneous plasmacytoma and a disseminated one.

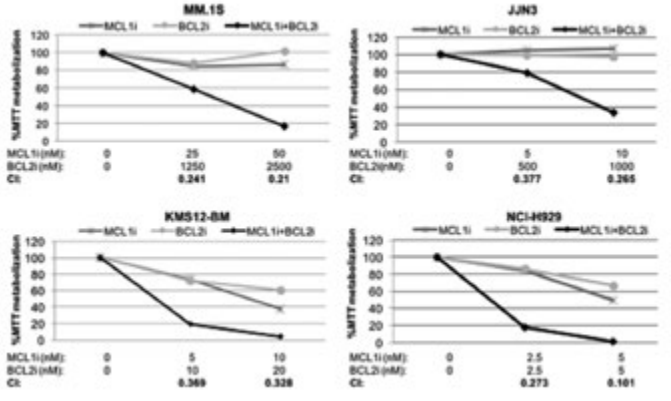

Figure 1.

Summary/Conclusion: Our preclinical data demonstrate the potent activity of the combination of MCL1 and BCL2 inhibitors (+/- dexamethasone) in MM, and provides the rationale for the clinical development of this combination in relapsed or refractory MM patients.

This project was supported by Norvartis Pharmaceuticals and by the Spanish Projects GRS 1604/A/17, ISCIII-FIS PI15/00067 and ISCIII-FIS PI15/02156.

S1579

PRECLINICAL EVALUATION OF THE NEW BCMAXCD3 BISPECIFIC ANTIBODY JNJ-957 FOR THE TREATMENT OF MULTIPLE MYELOMA

K. Frerichs[1,*], M. Broekmans[1], J. Marin Soto[1], B. van Kessel[1], A. Axel[2], C. Chiu[2], H. AdamsIII[2], S. Zweegman[1], T. Mutis[1], N. van de Donk[1]

[1]Hematology, VU University Medical Center, Amsterdam, Netherlands, [2]Research & Development, Janssen, Spring House PA , United States

Background: Multiple myeloma (MM) patients with disease refractory to all available treatments have a very poor outcome. B-cell maturation antigen (BCMA) is a tumor necrosis factor (TNF) family surface protein involved in differentiation of B-cells to plasma cells. The selective expression of BCMA on plasma cells renders it an attractive target for novel MM treatment strategies.

Aims: We evaluated the preclinical activity of a new BCMAxCD3 bispecific antibody (JNJ-957) for the treatment of MM. We also analyzed the biomarkers and T-cell subsets associated with the *in vitro* JNJ-957 response.

Methods: MM cell lysis by JNJ-957 was analyzed in MM cell lines and whole bone marrow (BM) samples from MM patients. In MM cell lines, peripheral blood mononuclear cells (PB MNC) from healthy donors or MM patients were used as effector cells. Serial dilutions of JNJ-957 (0.0064-4µg/ml) were incubated with the samples for 48 hours. The lysis of $CD138^{high}/CD38^{+}$ MM cells was assessed by flow cytometry. At baseline, the MNC were characterized for the composition of different T-cell subsets. JNJ-957 induced T-cell activation and degranulation were measured by the expression of CD25 and CD107a, respectively.

Results: JNJ-957 effectively killed $BCMA^{+}$ MM cell lines (NCI-H929 and RPMI8226) in a dose-dependent manner by healthy donor or MM patient derived PB MNCs . In newly diagnosed (ND)MM patient samples (n=8), the mean lysis of MM cells by JNJ-957 4.0µg/mL was 79% (range: 66-92%; figure 1A). Similar MM lysis, but with a larger variation, was achieved in lenalidomide (LEN) refractory patient samples (n=15; mean lysis at 4.0µg/mL: 69%; range: 24-98%; fig 1B), who were also bortezomib (73%), pomalidomide (82%) and carfilzomib (9%) refractory. JNJ-957 was also effective in samples from MM patients who were daratumumab (DARA) refractory (n=11; mean lysis at 4.0µg/mL: 83%; range: 52-99%; fig 1C). NK- and T-cell frequencies were not affected. JNJ-957-mediated MM cell lysis was associated with activation and degranulation of CD4+ and CD8+ T-cells.The heterogeneity in MM cell lysis by JNJ-957 could not be explained by BCMA or PD-L1 expression levels on MM cells, the presence of standard or high-risk cytogenetic abnormalities, or composition of T-cell subsets. Only at suboptimal JNJ-957 doses, the MM cell lysis was affected by high frequency of regulatory T-cells (Treg) and low frequency of effector memory (Tem) and terminally differentiated effector (TEMRA) T-cells. Since improvement in tumor reduction could be aided by the recently discovered immune stimulatory effects of DARA, we also analyzed sequential BM aspirates from MM patients before and after DARA treatment (n=5). Here we observed comparable BCMA expression, yet improved MM cell lysis by JNJ-957 in samples obtained after disease progression during DARA compared to samples before DARA initiation (mean lysis at 4.0µg/mL: 93 *vs* 74%; fig 1D).

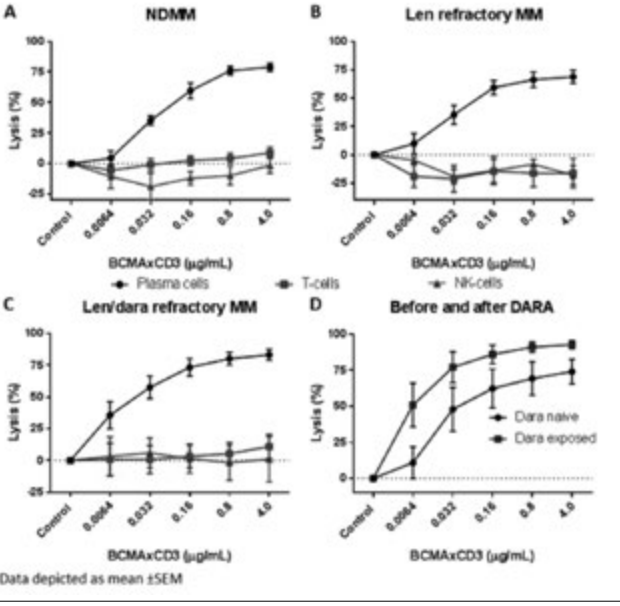

Figure 1.

Summary/Conclusion: The BCMAxCD3 bispecific antibody, JNJ-957, effectively lysed primary MM cells both in samples derived from heavily pretreated DARA-refractory patients and those with low BCMA surface expression. Optimal JNJ-957 dosing overcame the negative influence of high Treg and low Tem/TEMRA frequencies on the extent of MM cell killing. Our data also suggest that *in vivo* pretreatment with DARA improves the response to JNJ-957. Altogether, this strengthens the preclinical rationale for an ongoing phase 1 study with JNJ-957 in relapsed/refractory MM.

Inherited bone marrow failure including PNH

Background: *SAMD9L* and *SAMD9* are two genes located at chromosome 7q21 that encode for two large homologous proteins implicated in inflammatory and antiviral responses. While these genes can be lost somatically in myelodysplastic syndromes (MDS) (*Nagamachi, Cancer Cell 2013*), germline activating mutations have been recently associated to the autosomal dominant syndromes *Ataxia-Pancytopenia* (*SAMD9L gene; Chen, Am J Hum Genet 2016*) and *MIRAGE* (*SAMD9 gene; MDS, infection, restriction of growth, adrenal hypoplasia, genital phenotypes, and enteropathy*; *Narumi, Nat Genet 2016*). We and other have found that *SAMD9* and *SAMD9L* germline heterozygous mutations further defined a spectrum of bone marrow failure (BMF) and MDS genetic predisposition in children (*Tesi, Blood 2017*; Bluteau, *Blood 2017; Schwartz, Nat com 2017*).
Aims: In order to delineate better the SAMD9/SAMD9L associated disorder, we analyzed a cohort of 22 patients (pts) with germline *SAMD9* or *SAMD9L* mutations originating from 16 families.
Methods: Patients and relatives were originally investigated in the laboratory of the French Aplasia Center to search for a familial origin to their BMF or MDS. All subjects gave informed consent for genetic investigation, tissue banking and research, and this study was IRB approved. We here report the natural clinical history of 22 patients, with a median FU of 6 years (7 months-37y). In 14 of them, we analysed hematopoietic somatic events using WES and Sanger re-sequencing on blood or bone marrow samples, in comparison with fibroblast DNA.
Results: Fifteen and 7 pts with *SAMD9L* and *SAMD9* germline mutations were identified, from 9 and 7 unrelated families, with a median age at first hematological signs of 13 months (8 months-46y) and 7 years (2-21y), respectively. Six out of 15 *SAMD9L* pts had neurological signs and 1/7 *SAMD9* pts had a MIRAGE syndrome. Immunoglobulin deficiency with recurrent infections was found in both SAMD9 (N=4/7) and in SAMD9L (N=3/15) pts. Regarding hematological features, 20 pts had central cytopenia, with BM dysplasia in 11 and monosomy 7 in 10. Except one with an additional TERC germline mutation, patients did not present excess of blasts or cytogenetic lesion in addition to monosomy 7 at any point of their natural history. Ten had a family history while 12 presented simplex. Strikingly, spontaneous improvement in blood cell counts was seen in 11 pts, and MDS and monosomy 7 disappearance in 5 pts, with a median follow-up of 4 y. HSCT that was planned for five of these pts was eventually cancelled and they are still alive without consistent cytopenia with a follow-up of four to 33 years. Finally, two carrier subjects had no overt hematological signs. We sequenced blood and/or marrow mononuclear cells in 14 pts and found somatic changes such as acquired 7q uniparental disomy (UPD) or additional *SAMD9* or *SAMD9L* cis-mutations in 7 of them, suggesting spontaneous genetic correction of the germline mutated allele.
Summary/Conclusion: Germline mutations of *SAMD9* and *SAMD9L* delineate an inherited BMF/MDS predisposition disorder in children and young adults with frequent transient monosomy 7. Patients may benefit from a careful watch-and-wait policy rather than upfront HSCT, even when presenting with dysplasia and monosomy 7, a practice-changing option that will have to be carefully evaluated.

CHARACTERIZATION OF ORALLY BIOAVAILABLE SMALL MOLECULE INHIBITORS OF COMPLEMENT C5

A. Ricardo[1,*], M. Hale[1], Z. Ma[1], J. Reyes[1], C. Sayegh[1], K. Sherry[1], Y. Sun[1], Y. Tan[1], D. Vadysirisack[1], N. Zu[1]

[1]Ra Pharmaceuticals, Inc., CAMBRIDGE, United States

Background: Abnormal activation of the complement cascade is implicated in the pathogenesis of many rare and common diseases. Complement C5 inhibition by intravenous administration of the monoclonal antibody eculizumab has demonstrated therapeutic benefit in paroxysmal nocturnal hemoglobinuria (PNH), atypical hemolytic uremic syndrome (aHUS) and, most recently, in myasthenia gravis. Given the demonstrated and broad therapeutic utility of complement inhibition in these and other disorders, there is substantial interest in the development of an oral small molecule C5 inhibitor (C5SMi) as a treatment for autoimmune, hematological, renal, vascular and neurological diseases. We recently described the discovery of orally bioavailable small molecule inhibitors of complement C5. Here, we describe their pharmacology in human whole blood-based assay models, pharmacokinetics in several preclinical species, and their ex *vivo* PK/PD relationships.
Aims: -Characterize the pharmacology of orally available C5SMi in human whole blood-based models of disease; Determine the pharmacokinetic parameters of C5SMi in preclinical species (rodents and dog); Establish a PK/PD (ex vivo) relationship for orally available C5SMi in mice
Methods: Pharmacokinetic studies of C5SMi were conducted in rodents and dogs following intravenous and oral administration. Non-compartmental analyses were applied to the plasma concentration *versus* time data (PK analysis). Blood was drawn at multiple time points following administration to establish an ex-vivo PK/PD relationship by monitoring C5a formation after zymosan mediated complement activation (PD analysis). Potency in disease-relevant human whole blood studies was determined by ABO incompatibility reactions following mixing blood from a donor with serum from an incompatible recipient. Finally, a human whole blood hemolysis assay was performed using a polyclonal anti-human RBC antibody and hemolysis monitored using spectrophotometric methods.
Results: The pharmacokinetic data demonstrate that compounds within the lead series display dose proportional oral exposure and low clearance values in several preclinical species. *Ex vivo* and *in vitro* assays, including in human whole blood assays, demonstrate the selective engagement of complement C5, and the mouse PK/PD relationship following oral dosing informs the level of exposure required to achieve therapeutic efficacy in humans.
Summary/Conclusion: The results presented in here confirm the feasibility of inhibiting complement C5 using small molecule inhibitors via oral dosing. The excellent drug-like properties exhibited by these compounds, their favorable pharmacokinetic behavior in different preclinical species, and the understanding of the PK/PD relationship informs the required therapeutic drug levels that will be necessary to evaluate their pharmacology in human disease.

Background: Severe Congenital Neutropenia (SCN) due to ELANE mutations is usually managed with Granulocyte–Colony Stimulating Factor (G-CSF) but may also be amenable for treatment with Allogeneic Haematopoietic Stem Cell Transplantation (HSCT). According to the experts, HSCT is indicated in patients transformed into MDS/AL or who are refractory/poor responding to G-CSF (>20 mcg/kg/day). HSCT looks also appropriate for those subjects treated with G-CSF at doses between 10-20 mcg/kg/d, while the indications for those subjects managed with doses up to 10 mcg/kg are less clear.
Aims: To retrospectively compare the long term outcome of SCN-ELANE patients who underwent HCST *vs* those who did not, stratified according to G-CSF dose .
Methods: Data have been extracted from the Severe Chronic Neutropenia French registry (SCNFR), the Italian Neutropenia Registry (INR), from the database of the Severe Aplastic Anemia Working Group of the European Society for Blood and Marrow Transplantation (EBMT) and from Stem Cell Transplant for Immunodeficiencies in Europe (SCETIDE) in the years 1990-2017. The received dose of G-CSF was estimated by calculating the amount of drug that patients received for more than 75% of the treatment time (when daily dose was not available for the whole treatment period) or by calculating the mean dose (total amount/days of treatment) whenever daily dose was available for the full period. The cohort has been arbitrarly stratified in two subgroups according to the dose of G-CSF received: ≤10 mcg/kg/d, and >10 mcg/kg/d.
Results: 162 SCN ELANE patients were considered eligible for the study, 141 were treated with G-CSF and 52 received HSCT. Transplant indication was as per Center policy. Characteristics of the population are shown in Table 1. The 15 y-OS of the whole group was 91% (95% IC; 84-95). HSCT patients had worse survival *vs* those treated with G-CSF: 79% (95% IC; 52-92) *vs* 94% (95% IC 87-97) respectively (p=0.031). The 15y-OS of patients receiving G-CSF >11mcg/kg/d was 85% (95% IC; 51-96) *vs* 74% (95% IC 33-92) of HSCT patients (p 0.325). Transplanted patients receiving ≤10mcg/kg/d of G-CSF had significantly lower 15-yr OS if compared with the G-CSF treated subjects (74% -95% IC 24-94 *vs* 98% -95% IC 91-99-) (p=0.015). In the subgroup treated with G-CSF ≤10mcg/kg/d who underwent HSCT, 1 patients had AL, 1 had unmanageable infections and 5 had available an identical siblings. Comparison of OS in the two groups by additional "risk factors" other than CSF dose is ongoing.

Table 1.

TABLE 1 Characteristic of the cohort		Whole Cohort	Life time G-CSF pts N(%)	HSCT pts N(%)	P
No		162	141 (68%)	52(32%)	
Gender	M	72	49 (44%)	23 (44%)	ns
	F	90 (57%)	61 (66%)	29 (66%)	ns
Median age at last FUP (years)		12 (0.8-62)	14.4 (1.39-62)	8.8 (0.8-25)	<0.001
G-CSF µg/kg/day	**≤10**	**107**	**93**	**14**	**<0.001**
	>11	**41**	**13**	**28**	**<0.001**
	<5	**64 (60%)**	**28 (30%)**	**0 (0%)**	**0.01**
MDS/AL		5/6	0/2	4/5	<0.001
Deaths		13	7 (6%)	6 (11%)	ns
	GvHD	3	0	3	ns
	Infection	7	4	3	ns
	AL/other tumour	3	3	0	ns

Summary/Conclusion: This is the largest comparative analysis between HSCT and life-time G-CSF conducted in *ELANE*-SCN cohort . The OS of the whole cohort 91 % after 15 y of follow up. On the whole the HSCT group shows a significantly worse survival *vs* G-CSF treated one probably because a negative selection of the transplanted patients . However the OS of the group who received G-CSF ≤10mcg/kg/d and underwent HSCT was significantly inferior than that managed with G-CSF alone . This suggests that indication to transplant for patients receiving G-CSF dose ≤10mcg/kg/d needs to be carefully balanced. Definitive conclusion might be drawn at the completion of analysis including other factors that may affect the outcome like molecular characteristics, clonal evolution markers and infection load.

Background: Hemophagocytic syndrome (HLH, hemophagocytic lymphohistiocytosis) is a rare syndrome of fatal hyperinflammation, where cytokine storm leads to bone marrow failure and death. Historically it was mostly diagnosed in pediatric population, but with raising awareness data form adults are emerging. Little is known about prognostic factors in HLH, especially in adult patients.
Aims: Aim of this study was search for prognostic factors in one of the largest cohorts of European adult HLH patients.

Table 1.

Table 1. Prognostic factors for OS in adult HLH – in univariate and multivariate analyses

Factor	n	Univariate			Multivariate		
		HR	HR 95% CI	p	HR	HR 95% CI	p
MAS	86	0.146	0.035-0.602	0.008	0.161	0.038-0.686	0.014
Hepatomegaly	83	0.574	0.324-1.017	0.057	0.515	0.283-0.937	0.03
RBC	86	0.591	0.366-0.954	0.031			0.284
Trig>265mg/dl	84	0.559	0.315-0.993	0.047			0.249
AT III	25	0.04	0.002-0.656	0.024			
ESR	21	0.974	0.95-0.999	0.04			

MAS: Macrophage Activation Syndrome; RBC: red blood cell count; Trig: triglycerides; AT III: Antithrombin III; ESR: erythrocyte sedimentation rate.

Methods: Data of 86 adult (≥ 18 years of age) patients form the HLH in Adults Database affiliated with PALG (Polish Adult Leukemia Group) were retrospectively analyzed. Risk factor analysis was made by Cox regression. Factors were analyzed in univariable analysis, and factors with $p < 0.06$ and $n > 82$ were retained in the multivariable model. Statistica 13 and MedCalc 18 softwares were used.
Results: A slight male predominance (62%; 53/86) was observed in the analyzed group. Median age was 38 (18-82). Median survival reached 144 days, 35% of patients died within one month. Among 29 patients who survived over one year, only two died (both due to HLH relapse). Longest observation

exceeded 10 years. There were 34 patients with malignancy-associated HLH, 20 with infection-associated HLH, 14 with HLH associated with autoimmune disease (MAS syndrome; Macrophage Activation Syndrome). In 18 patients triggering factor could not be determined. In univariate analysis (Table 1) MAS syndrome, red blood cell count (RBC) and hypertriglyceridemia (>265mg/dl – HLH-2004 criterion cutoff) were established as positive prognostic factors. Additionally, a trend for hepatomegaly was observed (p=0.057). Interestingly, antithrombin III and ESR were also significant in univariate analysis, but low number of available results precluded them from being tested in multivariate analysis. Among four analyzed parameters in multivariate analysis only MAS and hepatomegaly retained the prognostic factor status (Table 1).

Summary/Conclusion: Hemophagocytic syndrome in adults confers a poor prognosis, but patients who survive the first critical period may expect survival with a low relapse risk. MAS syndrome and hepatomegaly may be associated with a relatively better prognosis in newly-diagnosed adult HLH patients.

THE FREQUENCY OF THE ETHNIC NEUTROPENIA-ASSOCIATED RS2814778 SNP OF DUFFY ANTIGEN RECEPTOR FOR CHEMOKINES (DARC) GENE IN A COHORT OF EUROPEAN PATIENTS WITH CHRONIC IDIOPATHIC NEUTROPENIA

I. Mavroudi[1], I. Fragiadaki[1], K. Axarlis[1], S. Papadakis[1], A. Batsali[1], S. Mastrodemou[1], P. Kanellou[1], A. Damianaki[1], M. Ximeri[1], G. Goulielmos[2], K. Sfyridaki[3], A. Mörtberg[4], J. Palmblad[5], P. Höglund[4,6], H. Papadaki[1,*]

[1]Haemopoieseis Research Laboratory, School of Medicine, University of Crete, and Department of Haematology, University Hospital of Heraklion, [2]Department of Internal Medicine, Molecular Pathology and Human Genetics Section, School of Medicine, University of Crete, [3]Blood Bank, Venizeleion General Hospital, Heraklion, Greece, [4]Department of Clinical Immunology and Transfusion Medicine, Karolinska University Hospital, [5]Departments of Medicine and Hematology, [6]Department of Medicine, Center for Hematology and Regenerative Medicine (HERM), Karolinska Institutet and Karolinska University Hospital, Huddinge, Sweden

Background: Chronic Idiopathic Neutropenia (CIN) is a mild bone marrow (BM) failure syndrome characterized by presence of myelosuppressive oligoclonal/monoclonal T-cell populations and usually benign course. The possible association of CIN with the Single Nucleotide Polymorphism (SNP) *GATA -67T>C* (rs2814778) of the Duffy Antigen Receptor for Chemokines (*DARC*), also known as Atypical Chemokine Receptor 1 *(ACKR1)* gene, associated with the benign Ethnic Neutropenia, has never been studied so far. This polymorphism is associated with the red blood cell Duffy Null phenotype; it is rare among individuals of European descent but common in Africans, African Americans and Yemenite Jews, populations characterized by the benign Ethnic Neutropenia. The mechanism of neutropenia implicates the Duffy-mediated regulation of chemokine gradients resulting in neutrophil influx from blood into the tissues.

Aims: The aim of the study was to evaluate the genotype and allele frequency of the rs2814778 SNP in patients with CIN living in the island of Crete, Greece.

Methods: We studied 50 patients (45 females, 5 males) fulfilling the previously defined diagnostic criteria of CIN. Specifically, the patients had absolute neutrophil counts (ANC) below $1800x10^6$/L (mean 1206 ± 477) at least for 3 months, no evidence of any underlying disease associated with neutropenia, no history of exposure to irradiation, use of chemical compounds or intake of drugs to which neutropenia might be ascribed, normal BM karyotype and negative antineutrophil antibodies. Two patients were of Balkan and one of English origin whereas the others originated from Crete. DNA was extracted from peripheral blood samples (Qiagen) and the genotyping for the rs2814778 SNP of the *DARC* gene was performed using the TaqMan SNP Genotyping Assay C__15769614_10 (Thermo Fisher Scientific).

Results: Four patients (one of Balkan and three of Cretan origin), representing a percentage of 8% of the CIN patients examined, were found to be homozygous for the C allele of rs2814778 (also designated as $FY*B^{ES}/FY*B^{ES}$); five patients (all of Cretan origin) *i.e.* a percentage of 10% were heterozygous (T/C or $FY*B/FY*B^{ES}$) for the *DARC* SNP under study. Red blood cell phenotyping was performed in one of the homozygous patients and was Duffy Null, as anticipated. No statistically significant differences were found between T/T CIN patients and the carriers of C allele (C/C or T/C) regarding gender, ANC, haemoglobin, lymphocytes and platelet counts. We also investigated the above groups for potential differences in parameters previously reported to characterize CIN. Specifically, we evaluated the serum immunoglobulin levels and the frequency of oligoclonal/monoclonal T-cell populations using flow-cytometric analysis but no significant differences were identified.

Summary/Conclusion: This is the first study demonstrating that the C/C ($FY*B^{ES}/FY*B^{ES}$) homozygosity of the rs2814778 SNP, implicated in Ethnic Neutropenia, is not rare among European patients with CIN. Therefore, the genotyping for rs2814778 SNP of *DARC* gene should be incorporated in the initial investigation of any patient with chronic unexplained neutropenia. We are currently investigating the correlation between the rs2814778 genotype and the red blood cell phenotype to simplify this initial screening and we are also organizing a large case-control study in Cretan population aiming to identify the genotype and allelic frequencies of the rs2814778 SNP and its potential association with the diagnosis of CIN.

Sickle cell disease and blood transfusion

S1585

RED CELL EFFECTS OF THE ANTI-CD47 MONOCLONAL ANTIBODY HU5F9-G4 IN A PHASE I STUDY FOR RELAPSED OR PRIMARY REFRACTORY ACUTE MYELOID LEUKEMIA

C. Brierley[1,*], J. Staves[1], C. Roberts[2], H. Johnson[3], P. Vyas[1,4], L. Goodnough[5], M. Murphy[1,6]

[1]Dept of Haematology, Oxford University Hospitals NHS Foundation Trust, [2]Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, [3]Oncology Clinical Trials Office, Department of Oncology, University of Oxford, [4]MRC Molecular Haematology Unit, University of Oxford, Oxford, United Kingdom, [5]Departments of Pathology and Medicine, Stanford University, Stanford, United States, [6]National Health Service Blood and Transplant, Oxford, United Kingdom

Background: CD47 is a physiological 'don't-eat-me' signal to cells of the innate immune system, and its blockade results in phagocytic clearance of tumor cells in animal models. Downregulation of CD47 triggers clearance of ageing red blood cells (RBC). Hu5F9-G4 (5F9) is a first-in-class antibody targeting CD47 being explored clinically in multiple tumors. In non-human primate studies 5F9 induced an on-target anemia by CD47 blockade and removal of circulating senescent RBC. 5F9 binding to RBCs may also confound blood type and antibody testing.
Aims: Here we report the red cell effects, impact on blood bank testing and transfusion management in a Phase I trial of 5F9 in relapsed or primary refractory AML.
Methods: 13 patients recruited at five centers in the U.K. were allocated to one of four escalating dose cohorts of 5F9. For each patient we collected serial data on hemoglobin (Hb), markers of hemolysis, transfusion requirements and any blood compatibility testing issues. On the day of each treatment, blood samples were taken pre-dose and post-dose (4 hrs +/- 30mins post infusion). Doses of 5F9 ranged from 0.1mg/kg to 15.0 mg/kg twice weekly. The cut-off for data collection was June 6 2017.
Results: All patients (13/13; 100%) experienced a decline in Hb between the pre- and post-dose blood samples. The median Hb decline following any dose of 5F9 across the course of the study was 1.2 g/dL (range 0.4 to 1.6). In 3 patients (23%), the Hb decreased post- 5F9 by ≥3 g/dL, all after the first dose. The maximum observed Hb drop in any patient was 5.2 g/dL. There was no consistent laboratory evidence of hemolysis as evaluated by bilirubin, LDH or reticulocyte counts. 13/13 patients (100%) developed evidence of RBC agglutination on blood smear examination. No related clinically significant sequelae were observed. 12/13 (92%) of patients developed a positive direct antiglobulin test (DAT). DAT positivity was strongest after the first dose of 5F9 but remained detectable in 6/13 patients (48%) at end of treatment period. All patients (13/13; 100%) were transfused on-trial to a target Hb of 8-10g/dL. Transfusion requirements were higher on trial than pre-trial but this may be partially explained by a higher Hb threshold for transfusion after patients entered the trial. The median increment per unit of RBC was 1.0 g/dL which was maintained until the subsequent dose of 5F9. Discordant results from forward and reverse ABO typing were seen in 3/13 (23%), due to extra plasma reactivity in the reverse typing. 7/13 (54%) patients were found to have a positive antibody screen. In 6/13 (48%) patients this was a pan-agglutinin, and in 1/13 (8%) a known anti-E antibody. The median time to positive antibody screen was 2 days (range 2-114). Patients with a pan-agglutinin required matching of donor blood to the patient's genotype to provide RBC for transfusion. All patients were safely transfused with no clinical complications. The antibody effect could not be abolished with DTT, chloroquine, papain, ficin, or trypsin.
Summary/Conclusion: AML patients treated with 5F9 may experience a decline in Hb and increased transfusion requirements. The likely mechanism of anemia in AML patients is clearance of aged RBCs by CD47 blockade, combined with a failure to mount a compensatory reticulocytosis. Type-specific RBC based on baseline ABO blood group may be required where ABO typing interference occurs. Issues with compatibility testing because of newly positive antibody screens in ~50% of patients can be mitigated by pre-treatment geno/phenotype matching. Safe red cell transfusions were possible in all patients.

S1586

THE EFFECT OF COMPLEMENT INHIBITOR CP40 ON ERYTHROCYTE DESTRUCTION IN AIHA

I. Baas[1,*], P. Ligthart[2], C. Brouwer[2], C. Folman[2], E. Reis[3], D. Ricklin[3], J. Lambris[3], D. Wouters[1], M. de Haas[2], S. Zeerleder[1,4]

[1]Department of Immunopathology, [2]Sanquin Diagnostic Services, Sanquin, Amsterdam, Netherlands, [3]Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, United States, [4]Department of Hematology, Academic Medical Center, Amsterdam, Netherlands

Background: Autoimmune hemolytic anemia (AIHA) is a rare disease characterized by autoantibodies against erythrocytes. These autoantibodies may activate the classical complement pathway leading to opsonization by complement proteins C3b and C4b. This results in increased clearance of erythrocytes by phagocytes, called extravascular hemolysis. Occasionally, complement activation results in formation of the membrane attack complex (MAC), causing intravascular hemolysis. C3-inhibitor compstatin inhibits C3 activation and thus it is expected to reduce both, C3b deposition as well as well as formation of the MAC. Therefore, compstatin is a potentially efficient inhibitor of extra- and intravascular hemolysis in AIHA.
Aims: The current aim of this research is to investigate *in vitro* whether compstatin would be a suitable drug for AIHA treatment.
Methods: Healthy donor erythrocytes treated with bromelin were incubated with AIHA patient serum together with anti-C5 so that opsonization could be analyzed by FACS using anti-C3-FITC and anti-C4-APC antibodies. In the absence of eculizumab, hemolysis of RBCs was tested by measuring the extinction at 412/690 nm. The percentage hemolysis was calculated relative to the 100% water control. To assess the effect of compstatin cp40 on uptake of erythrocytes by phagocytes, erythrocytes were fluorescently labeled with PKH26 before opsonization. Monocytes isolated by leukapheresis were cultured for 8 or 9 days in the presence of 10 ng/mL GM-CSF to obtain M1-like macrophages or 50 ng/mL M-CSF to obtain M2-like macrophages. Opsonized erythrocytes were then incubated with healthy monocyte derived macrophages and phagocytosis of erythrocytes was measured with ImageStream after lysing the non-phagocytosed erythrocytes.
Results: Complement deposition and MAC formation was induced by AIHA serum via the classical pathway of complement, while this activation was efficiently inhibited by EDTA and other inhibitors, *e.g.* C1-inhibitors. In these systems, it was shown that compstatin completely inhibited C3 deposition on erythrocytes, while unexpectedly C4 deposition appeared to be increased. Regardless of the increase in C4, compstatin prevented formation of the MAC and RBC lysis. In addition, compstatin inhibited complement-mediated phagocytosis of erythrocytes by M1 macrophages while the effect on phagocytosis by M2 macrophages was less pronounced. When erythrocytes opsonized with both complement and IgG phagocytosis inhibition with compstatin was less efficient as compared to the inhibition of phagocytosis of erythrocytes opsonized with complement only.
Summary/Conclusion: We demonstrate that compstatin inhibits C3b deposition, C3-mediated phagocytosis of opsonized RBCs as well as MAC formation. Therefore, compstatin is a potential candidate for therapeutical application in AIHA patients to inhibit both intra- and extravascular hemolysis.

S1587

INTRAVASCULAR HEMOLYSIS INDUCES COMPLEMENT SYSTEM ACTIVATION MEDIATED BY HEME AND HEME-LOADED ERYTHROCYTE MICROVESICLES

L. Roumenina[1,*], N. Merle[1], V. Fremeaux-Bacchi[2], O. Blanc-Brude[3]

[1]INSERM UMRS[1138] Cordeliers Research Center, INSERM UMRS[1138] Cordeliers Research Center, [2]HEGP, APHP, [3]Paris Center for Cardiovascular Research, INSERM UMR_S [970], F-[75015], Paris, France, Paris Center for Cardiovascular Research, INSERM UMR_S [970], F-[75015], Paris, France, Paris, France

Background: In hemolytic diseases like sickle cell disease (SCD), intravascular hemolysis results in the release of hemoglobin, heme and heme-loaded membrane microvesicles in the bloodstream. Intravascular hemolysis is then associated with inflammation and organ injury. Our previous studies have demonstrated that the complement system can be activated by heme *in vitro.* However, the interrelation of intravascular hemolysis, complement activation and tissue damage remains unknown.
Aims: Our objective was to investigate the mechanisms by which hemolysis and red blood cells degradation products trigger complement activation *in vivo.*
Methods: We evaluated the deposits of C3 activation fragments and C5b-9 in kidneys of SCD patients (n=11) and two transgenic mouse models (SAD and Townes) by immunofluorescence and immunohistochemistry. Intravascular hemolysis was induced in C57Bl/6 mice by injection of phenylhydrazine in presence or not of hemopexin. The complement deposits in the kidneys were followed. RBC microvesicles were generated *in vitro* from erythrocytes of SCD patients or healthy donors. Complement activation (Ba, sC5b-9) in normal human serum was measured by ELISA. Complement deposits on cultured endothelial cells and their activation status was evaluated by flow cytometry.

Results: We analyzed kidney biopsies of patients with SCD nephropathy and model mice with SCD. We detected significant tissue deposits of complement C3 and C5b-9. Moreover, drug-induced intravascular hemolysis or injection of heme in mice triggered C3 deposition, primarily in the kidneys. Red blood cells degradation products like heme-loaded microvesicles and free heme induced alternative and terminal complement pathway activation in normal serum and on EC surfaces, contrary to hemoglobin. Heme triggered rapid P-selectin, C3aR and C5aR expression and down-regulated CD46 expression on EC. Importantly, complement deposition was attenuated *in vivo* and *in vitro* by hemopexin, the potent heme scavenger.
Summary/Conclusion: In conclusion, we describe for the first time that intravascular hemolysis triggers complement activation *in vivo*, and is associated with SCD nephropathy. Conversely, heme inhibition using hemopexin may provide a novel therapeutic opportunity to limit complement activation in hemolytic diseases.

GENOME WIDE ASSOCIATION STUDIES (GWAS) OF CEREBROVASCULAR EVENTS IN PATIENTS WITH SICKLE CELL ANAEMIA (SCA)

J. Brewin[1,*], K. Gardner[1], S.L. Thein[2], S. Menzel[1], D. Rees[1]

[1]Red Cell Biology, Kings College London, London, United Kingdom, [2]Sickle Cell Branch, National Heart, Lung and Blood Institute, Bethesda, United States

Background: Patients with SCA are at significantly increased risk of cerebrovascular disease (CVD). The role of genetics in the pathogenesis of CVD is supported by analysis of sibling pairs in both stroke outcomes and cerebrovasculopathy as detected by abnormal transcranial Doppler (TCD) studies. Another form of CVD in SCA are silent cerebral infarcts (SCI). These do not cause overt clinical signs, but are associated with reduction in IQ.
Aims: To perform genome wide association analysis of CVD outcomes in patients with SCA.
Methods: The south east London sickle cell disease genebank contains 832 African-Caribbean or West African heritage patients with datasets for 16.7 million non-monomorphic variants based on the Illumina Infinium MEGA chip plus imputation using the Michigan imputation server with 1000 genomes data. All available clinical neuroimaging reports (CT scans, MRI/A scans and TCDs) were reviewed to determine evidence of overt ischemic stroke (OIS), SCI and the highest TCD velocity recorded. Clinical notes were also reviewed to confirm OIS. We performed GWAS on OIS, SCI, max TCD, and a fourth composite "global" CVD outcome. Analysis used linear mixed modelling to account for genetic relatedness, with age and sex as fixed covariates. Duplicate samples, and one of a pair of genetically identified 1st or 2nd degree relatives, were removed. Each model was assessed with λ_{GC} and a QQ plot to evaluate genomic inflation.

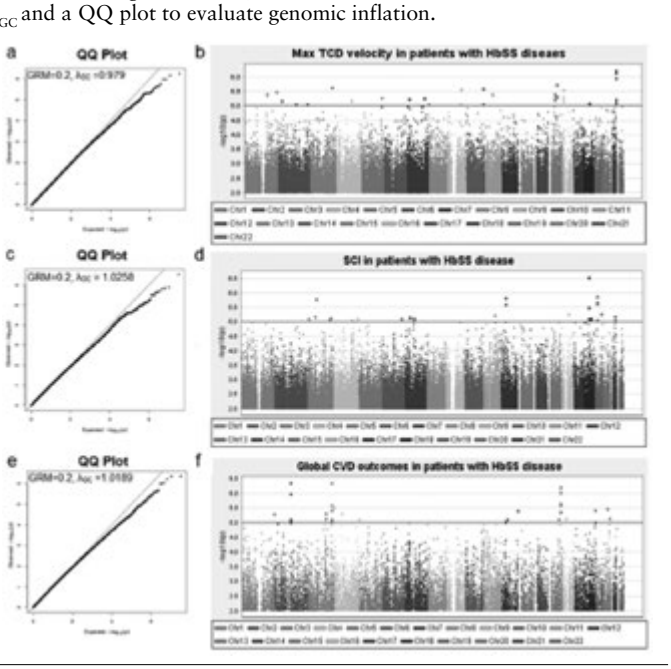

Figure 1.

Results: Although no variants achieved genome wide statistical significance, we investigated the most promising variant clusters seen on each Manhattan plot. A GWAS for TCD velocities was performed on 167 patients. The most significant peak was on chromosome 21 (rs2898354, Mean Allele Frequency (MAF)=0.43, p=5.69e^{-07}). These variants sit within intron 4 of the *ERG* gene, which has previously been associated with stroke in SCA. A cluster was also found on chromosome 9 (rs75829124, MAF=0.03, p=8.53e^{-06}) within 40kB of the *TGFBR1* gene. *TGFBR3* has previously been associated with stroke in SCA, and *TGFBR1* may have a role in the same pathway. A cluster (rs8032902, MAF=0.2, p=4.02e^{-06}) on chromosome 15 sits 40kB upstream of *fibrillin 1*, the major constitutive element of extracellular microfibrils in blood vessels. A GWAS for the SCI outcome was performed on 292 patients. The most promising cluster (rs879261, MAF=0.5, p=6.53e^{-06}) sits on chromosome 21 within intron 28 of the *intersectin1* gene. *Intersectin1* is involved in the endocytosis of Integrin beta-1 and transferrin. The GWAS model for OIS (n=317) showed evidence of genomic inflation. Modelling difficulties were likely due to the small number of patients with a positive event. Further analysis will be considered when more patients are recruited. A GWAS for global CVD was performed on 365 patients. A cluster of variants (rs150417193, MAF=0.2, p=7.47e^{-06}) on chromosome 15, sit within a copy number variant affecting a transcription factor binding site ~15kB upstream of *ADAMTS7*. The *ADAMTS* family have shown association with pediatric stroke and cardiovascular traits in the general population.
Summary/Conclusion: This is one of the largest studies looking at the genetics of CVD in SCD. We performed GWAS on a number of cerebrovascular outcomes in SCA. Although no result achieved genome-wide statistical significance, we have identified areas worthy of further validation. The most significant finding is a cluster of variants that fall within *ERG*, an erythroblast transformation-specific transcription factor that has a role in vascular cell remodelling, supporting previously published associations with this gene and CVD in SCA.

S1589

NOVEL INSIGHTS INTO SPLEEN INJURY DURING THE FIRST 2 YEARS OF LIFE IN SCA CHILDREN: A LONGITUDINAL STUDY

S. El Hoss[1,*], S. Cochet[1], M. Dussiot[2], M. Marin[1], C. Pereira[1], C. Lapoumeroulie[1], M. De Montalembert[3], C. Le Van Kim[1], Y. Colin Aronovicz[1], W. El Nemer[1], V. Brousse[1,3]

[1]Biologie Intégrée du Globule Rouge UMR_S[1134], Inserm, Univ. Paris Diderot, Sorbonne Paris Cité, Univ. de la Réunion, Univ. des Antilles, [2]INSERM UMR[1163], CNRS ERL[8254], Laboratoire d'excellence GR-Ex, Université René- Descartes, Imagine Institute, [3]Service de Pédiatrie Générale, Hôpital Necker-Enfants Malades, Centre de Référence de la Drépanocytose, AP-HP, Paris, France

Background: In sickle cell anemia (SCA), the spleen is the first organ to be injured notably because impaired deformability and/or adhesion of sickled RBCs promotes their sequestration. Moreover, acute splenic sequestration crisis (ASSC), a life-threatening complication, happens in 10-30% of SCA infants, with 75% of first cases occurring before the age of 2 years. Determinants, predictive factors and consequences of ASSC are not established.
Aims: Our study aims to evaluate the natural history of spleen dysfunction in a cohort of 47 SCA infants enrolled at 3-6 months and longitudinally followed-up to 24 months. Specifically, we analyzed RBC deformability and adhesion properties as potential determinants of ASSC and spleen injury.
Methods: ASSC were recorded prospectively and defined by the sudden enlargement of spleen (> 2 cm compared to basal) with a decrease of Hb level (> 2 g/dL compared to previous measurement). Blood samples were analyzed at enrollment and at 12, 18 and 24 months. Evaluation of spleen function was based on quantification of Howell Jolly Bodies (HJB) using an imaging flow cytometry (IFC) based method. Irreversibly sickled cells (ISCs) as a marker of RBC decreased deformability were quantified by IFC. Expression, activation and adhesion function of Lu/BCAM, a known erythroid marker, were quantified using flow cytometry, phosphorylation and dynamic adhesion assays.
Results: At enrollment, patients had HJB in circulation slightly higher than healthy controls (0.3% and 0.1%, respectively). Expectedly, a significant increase in HJB at 18 months (0.8%) was observed. At enrollment, there was no significant difference in HJB between infants who underwent ASSC (n=7) during the follow-up period, as compared to the group that remained both asymptomatic and ASSC-free (n=16). However, the ASSC group showed significantly higher HJB at 24 months as compared to the ASSC-free group (1.52% and 0.54%, respectively), a finding demonstrating that ASSC significantly decreases spleen function. Exploring the role of decreased deformability of RBCs in spleen injury, we observed the presence of ISCs at enrollment (0.96%) and a significant increase in ISCs at 18 months (1.61%). Moreover, the ASSC group showed significantly higher ISCs at enrollment than the ASSC-free group (1.61% and 0.54%). Thus, ISCs appear in the

circulation before the occurrence of an ASSC, indicating a potential role as a predictive marker of ASSC. Abnormal adhesion of RBCs to the spleen matrix in the open microcirculation might be another factor causing splenic injury. In particular, the spleen is lined with laminin, a known ligand for Lu/BCAM. We observed an increase in the expression and activation of Lu/BCAM with time. Moreover, we observed a significant increase in the number of adherent RBCs on laminin-coated channels between enrollment and 24 months (990 RBCs/mm^2 and 1787 RBCs/mm^2, respectively). However, there was no difference with respect to Lu/BCAM adhesion, expression and activation properties when comparing the ASSC group and the ASSC-free group.
Summary/Conclusion: Our study shows that spleen dysfunction is initiated as early as 4 months of age in SCA infants. ASSC greatly contributes to spleen loss of function. Changes in RBC properties including morphology, expression and activation of Lu-BCAM are initiated very early in infancy and increase with age. Importantly, we show that ISCs are a predictive marker of ASSC. Impairment of RBC deformability rather than adhesion plays a major role in spleen trapping and thereafter loss of function.

SPECIFICATION OF HEMATOPOIETIC STEM CELL FATE VIA MODULATION OF MITOCHONDRIAL ACTIVITY

M. Girotra[1,*], M. Rincon-Restrepo[1], C. Monnard[2], G. Coukos[1], S. Rezzi[2], N. Vannini[1]

[1]Ludwig Institute for Cancer Research, University of Lausanne, Epalinges, [2]Nestlé Institute of Health Sciences SA, Lausanne, Switzerland

Background: A tight control of hematopoietic stem cell (HSC) fate is crucial for lifelong blood production. Therefore, a fine balance of quiescence, self-renewal, and differentiation is key to maintain the HSC pool and blood homeostasis. In recent years cellular metabolism has emerged as a crucial regulator of HSC fate. HSCs differ from their committed progeny by relying primarily on anaerobic glycolysis rather than mitochondrial oxidative phosphorylation for energy production. However, whether this change in the metabolic program is the cause or a consequence of the unique function of HSCs remains unknown.
Aims: Here we asked if mitochondrial activity can be used as a reliable readout for functional HSCs and if modulation of mitochondrial activity results in enhancement of HSC function.
Methods: We used *in vivo* long term blood reconstitution assays as a readout of HSC functionality.
Results: We previously demonstrated that modulation of mitochondrial metabolism affects HSC fate, by chemically uncoupling the electron transport chain we were able to maintain HSC function in culture conditions that normally induce rapid differentiation (Vannini N, Girotra M. et al., Nat Comm 2016). Moreover, we demonstrated that modulation of mitochondrial activity in *ex-vivo* cultured human HSCs, via NAD+ boosting agent Nicotinamide Riboside (NR), results in better long-term blood production in serially transplanted humanized mice (*Under Revision*). Here we proceeded to carry out a mini screen, using mitochondrial activity as readout, to identify novel metabolic modulators that can be used to enhance HSC activity and function.
Summary/Conclusion: Our data thus reveal a causal relationship between mitochondrial metabolism and fate choice of HSCs, and also provide a valuable tool to identify optimal *ex vivo* conditions for HSC expansion and improve the outcome for patients suffering from bone marrow insufficiency.

P53 DEFICIENCY DRIVES LEUKEMIC TRANSFORMATION OF HEMATOPOIETIC STEM CELLS BY MAINTAINING QUIESCENCE IN RESPONSE TO DNA DAMAGE

A. Brown[1,*], M. Mulaw[2], J. Pospiech[1], K. Eiwen[1], M. Sacma[1], V. Sakk[1], B. Moehrle[1], K. Nattamai[3], K. Nalapareddy[3], H. Geiger[1,3]

[1]Ulm University, Institute for Molecular Medicine, [2]Ulm University, Institute for Experimental Cancer Research, Ulm, Germany, [3]Cincinnati Children's Hospital Medical Center and University of Cincinnati, Division of Experimental Hematology and Cancer Biology, Cincinnati, OH, United States

Background: The tumor suppressor gene *p53* is pivotal for DNA damage response pathways by forcing cell cycle arrest, DNA repair and apoptosis. Hence, *p53* is among the most frequently altered genes in cancer and its mutations are associated with large numbers of hematopoietic neoplasms, including MDS and AML. In hematopoietic stem cells (HSCs) p53 has been reported to be crucial for self-renewal, senescence and quiescence. Considering that very often leukemia emerges from stem and progenitor cells, it is remarkable that it still remains unclear how p53 activity prevents their transition to leukemia.
Aims: To investigate mechanisms that facilitate genomic and functional stability of the HSC pool and how p53 deficiency alters the functionality and the mutational landscape of HSCs in response to DNA damage.
Methods: We employed *P53*$^{-/-}$ mice together with wild type C57BL/6 mice to examine *in vivo* changes in cell cycle distribution and apoptosis levels of HSCs and less primitive progenitors in response to DNA damage. In this context, we also applied several assays to assess DNA repair pathways and changes in functionality of these cells. We visualized single HSCs within their bones by whole-mount immunofluorescence staining following confocal imaging. We performed transplantation experiments to study the consequences of HSC-associated DNA damage on the recipient mice. The detection of single point mutations and insertions/deletions was performed by sorting donor-derived HSCs following RNA-seq analysis and a bioinfor-

matic approach which extracts information about mutation frequencies out of these data.
Results: Here, we report a surprising new role of p53 in ensuring the integrity of HSCs: As previously reported, upon DNA damage HSCs from wild type mice enter the active cell cycle while simultaneously forcing apoptosis. HSCs from mice devoid of p53, however, preserve their quiescent state, protecting them from cell death. These HSCs exhibit a high abundance of 53BP1 foci suggesting a constitutive preference for the error prone non-homologues end joining pathway. These features are of cell-intrinsic and niche-independent nature, primarily stem cell specific and not present in more committed progenitors irrespective of p53. We demonstrate that *p53*$^{-/-}$ HSCs display persistently high P57(Kip2) levels after DNA damage offering a functional explanation for the observed phenotype. Indeed, *P53/P57* double deficient HSCs react similar to irradiation induced DNA damage in comparison to their wild type counterparts. Importantly, transplanted *p53*$^{-/-}$ HSCs engraft massively in the bone marrow several months after sublethal irradiation, severely lose their differentiation potential and the corresponding recipient mice develop early symptoms of leukemia, such as increased spleen sizes and high numbers of blast cells in the bone marrow. Strikingly, the single point mutation frequency of *P53*-deficient HSCs isolated from these mice is not notably high whereas we observe a global increase of insertions/deletions near splice sites and intron regions of protein coding genes. These observations imply that initial steps of transformation are not solely driven by the accumulation of mutations but specific changes in the mutational landscape stimulate the transformation process of HSCs.

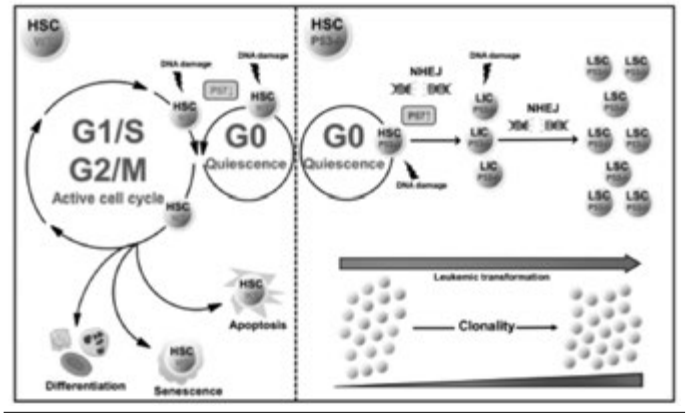

Figure 1.

Summary/Conclusion: In compliance with our previously published data we believe that we have found evidence for a novel p53-dependent pathway, forcing DNA-damaged HSCs out of quiescence to enable their removal. This proposed mechanism may turn out to play a crucial role in preventing the leukemic transformation of these cells.

OVEREXPRESSION OF THE TRANSCRIPTION FACTOR CDX2 IN HAEMATOPOIETIC STEM CELLS PREDISPOSES TO HAEMATOLOGICAL MALIGNANCIES

T. Vu[1,*], J. Straube[1], A. Song[1], V. Ling[1], C. Scholl[2,3], S. Fröhling[2,4], G. Magor[5], A. Perkins[5], S. Gröschel[2], J.-P. Mallm[3], S. Lane[1,6]

[1]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [2]National Center for Tumor Diseases (NCT), [3]German Cancer Research Center (DKFZ), [4]Heidelberg University Hospital, Heidelberg, Germany, [5]Australian Centre for Blood Diseases, Melbourne, [6]Royal Brisbane and Women's Hospital, Brisbane, Australia

Background: The caudal-related homeobox gene *CDX2* is ectopically expressed in 90% of human acute myeloid leukaemia (AML), but not normal haematopoietic cells. Retroviral expression of Cdx2 causes AML *in vivo*, while CDX2 knockdown impairs growth of AML cell lines *in vitro*. These findings implicate Cdx2 overexpression as a clinically relevant event in leukaemogenesis, however existing studies have been limited by the requirement for *ex vivo* manipulation, retroviral overexpression and transplantation.
Aims: To understand the role of Cdx2 in *de novo* leukaemic transformation on a molecular and cellular level.
Methods: We generated an inducible transgenic mouse model whereby Cdx2 was specifically activated in haematopoietic stem cells (HSC) using the tamoxifen-inducible Scl-CreER^{T2}. We performed immunophenotyping, whole exome sequencing, RNA-sequencing, ATAC-sequencing, and *in vivo* treatment of leukaemic mice with the hypomethylating agent Azacitidine.
Results: Scl-CreER^{T2}:Cdx2 mice developed a dysplastic phenotype which progressed in some mice to either myelodysplastic syndrome (MDS, 35%), myeloproliferative/MDS overlap (20%) or acute leukaemia (25%) after a long latency. Competitive transplantation assays showed intrinsic loss of long-term HSC self-renewal. Transcriptional analysis revealed an anti-apoptotic, pro-proliferative gene signature, suggesting Cdx2 overexpression confers a pre-leukaemic phenotype permissive to transformation upon acquisition of secondary mutations. Mechanistically, Scl-CreER^{T2}:Cdx2 mice showed marked depletion of long-term HSC and abnormal cell cycle regulation. Whole exome sequencing indicated that Cdx2 acute leukaemia developed in the presence of pathogenic secondary mutations including Ikzf1, Notch1 and Kit. ATAC-sequencing for chromatin accessibility revealed widespread chromatin changes at haematopoietic-specific enhancers. These motifs include Runx1, Pu.1:Irf8, C/ebp and C/ebp , which are key lineage determinants in haematopoietic stem and progenitor cells. Intriguingly, we observed complete repression of *Hox* cluster genes, challenging the notion that HOX activation drives leukaemia transformation in CDX2-positive leukaemia. Scl-CreER^{T2}:Cdx2 leukaemias were treated with azacitidine, a hypomethylating agent approved for high-risk MDS and AML patients. Azacitidine treatment prolonged survival and decreased leukaemic burden, associated with *in vivo* differentiation and selective apoptosis of Kit-positive leukaemia stem cells.
Summary/Conclusion: Altogether, this work demonstrates that conditional Cdx2 expression in HSC is a novel, inducible model of *de novo* leukaemic transformation and reflects common genetic aberrations seen in human AML. This may help to identify tractable susceptibilities to target leukaemia cells and improve clinical outcomes.

PERIVASCULAR NICHE CELLS SENSE THROMBOCYTOPENIA AND ACTIVATE PLATELET-BIASED HSCS IN AN IL-1 DEPENDENT MANNER

T.C. Luis[1,2], *, N. Barkas[1,2], A. Giustacchini[1,2], B. Wu[1,2], T. Bouriez-Jones[1], I.C. Macaulay[1], C. Nerlov[2], S.E. Jacobsen[1,2,3]

[1]Haematopoietic Stem Cell Laboratory, MRC Weatherall Institute of Molecular Medicine, [2]MRC Molecular Haematology Unit, MRC Weatherall Institute of Molecular Medicine, University of Oxford, Oxford, United Kingdom, [3]Department of Cell and Molecular Biology and Department of Medicine Huddinge, Center for Hematology and Regenerative Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Hematopoietic stem cells (HSC) are responsible for the on demand production of mature blood cells both in homeostasis and in response to stress situations such as injury and infection. HSCs reside in specialized niches in bone marrow (BM), which regulate their function. These niches are perceived as dynamic entities with the capacity to sense and respond to specific requirements in blood cell production, but the mechanisms underlying this dynamic regulation remain unclear. Accumulating evidence indicate that HSCs are highly heterogeneous, and different BM niches have been proposed, potentially supporting different subsets of HSCs. We recently identified a distinct subset of HSCs, which are molecularly and functionally primed for platelet replenishment (Carrelha J. *et al*, Nature 2018). However, the role of the niche in the regulation of platelet-biased HSC function is still unknown.
Aims: This work aims at investigating the role of the BM niche in the response of platelet-biased HSCs to platelet depletion.
Methods: Thrombocytopenia was induced in mice by the administration of an antibody against the platelet GPIb receptor, leading to fast and efficient platelet depletion. We used a RNA-sequencing approach to analyze different BM niche cell populations and HSCs in order to identify signals involved in the HSC response to platelet depletion.
Results: Platelet-biased HSCs are rapidly and selectively recruited into cell cycle in response to platelet depletion, through a feedback mechanism to replenish platelet numbers and homeostasis. Here we identified Interleukin-1 (IL-1) as a cytokine released upon acute platelet depletion and specifically sensed by niche LepR^{+} perivascular cells. Abrogation of IL-1 signaling specifically in LepR^{+} niche cells but not in hematopoietic cells impaired the platelet-biased HSC response to platelet depletion. This process was found to be dependent on platelet activation.
Summary/Conclusion: This work uncovers a molecular mechanism involving the pro-inflammatory signal IL-1 and the niche perivascular cell compartment in the rapid activation of platelet biased HSCs to thrombocytopenia, highlighting a mechanism by which a distinct subclass of HSCs senses and responds to the loss of the lineage for which it is intrinsically primed for.

SINGLE-CELL PROFILING REVEALS KEY DIFFERENCES IN THE CELLULAR ARCHITECTURE OF HUMAN HAEMATOPOIETIC STEM AND PROGENITOR CELLS THROUGHOUT FETAL AND ADULT LIFE

A. Roy[1,*], B. Psaila[2], S. Thongjuea[3], N. Ashley[4], G. Buck[1], S. O'Byrne[1], N. Elliott[1], E. Louka[2], N. Fordham[2], P. Hua[4], B. Povinelli[2], E.F. Heuston[5], D. Iskander[6], A. Karadimitris[6], D.M. Bodine[5], A. Mead[2], I. Roberts[1,2]

[1]Paediatrics, University of Oxford, [2]MRC Molecular Haematology Unit, MRC Weatherall Institute of Molecular Medicine, [3]RDM Clinical Laboratory Science, University of Oxford, [4]RDM Clinical Laboratory Science, MRC Weatherall Institute of Molecular Medicine, Oxford, United Kingdom, [5]National Human Genome Research Institute, National Institutes of Health, Bethesda, United States, [6]Centre for Haematology, Imperial College London, London, United Kingdom

Background: Mature blood cells of multiple lineages are constantly replenished throughout life. In humans, definitive haematopoiesis in the fetal liver (FL) commences at around 5 weeks of gestation, which remains the main site of haematopoiesis throughout fetal life. Haematopoiesis in the bone marrow (BM) starts around 11-12 weeks of gestation, but does not take over as the primary site of haematopoiesis until just after birth. Currently, we know very little about how haematopoietic stem/progenitor cell (HSPC) subsets change through ontogeny; and whether they do so in a site and stage-specific manner. Single cell RNA sequencing (scRNASeq) techniques now offer unprecedented opportunities to finely dissect the heterogeneity within specific HSPC populations and compare the cellular architecture of different sites of haematopoiesis.
Aims: To characterise the human HSPC compartment from early fetal life to adulthood using scRNAseq.
Methods: Lineage-negative, CD34+ cells from first trimester FL (n=2; gestation week 7-8); matched second trimester FL and fetal BM (FBM) (n=2 each; week 18-19); and healthy adult donor mobilised apheresis HSPC (n=2) were FACS-isolated for scRNAseq using the Chromium 10X platform. Data was processed using CellRanger, Seurat, Partek Flow® packages and in-house pipelines to perform dimensionality reduction, unsupervised clustering (tSNE) and to generate KNN graph differentiation trajectories.
Results: Data was obtained from 5000-9000 cells per sample. After filtering and quality control, data from around 49000 cells from the 8 samples was used for comparative analysis. The mean read count/cell was 47000 and the median gene count/cell was 2500 with 66-70% mapping. The composition of Lin-CD34+ cells was clearly distinct in different stages of ontogeny, with the early FL samples showing a substantially higher proportion of megakaryocyte-erythroid (MkE) progenitors, which decreased during development and in adult life (Fig 1). HSPC composition also varied in a site-specific manner as evidenced by differences seen in matched 2nd trimester FL and FBM samples from the same fetus. Second trimester FBM showed a B lymphoid bias compared to all other tissues including the matched FL samples. Further characterisation of normal and abnormal postnatal BM is currently underway.
Summary/Conclusion: We have used scRNAseq to analyse the CD34+ HSPC compartment throughout human ontogeny for the first time. There is clear evidence that this compartment varies in its composition and differentiation potential in a site and developmental stage-specific manner, as it may be dependant on the physiological processes/ demands of that particular developmental stage; and/ or in response to specific microenvironmental cues. Studying haematopoiesis throughout the human lifespan may be important not only to understand normal developmental processes, but also to understand the pathogenesis of postnatal haematological diseases that may have their origins in fetal life.

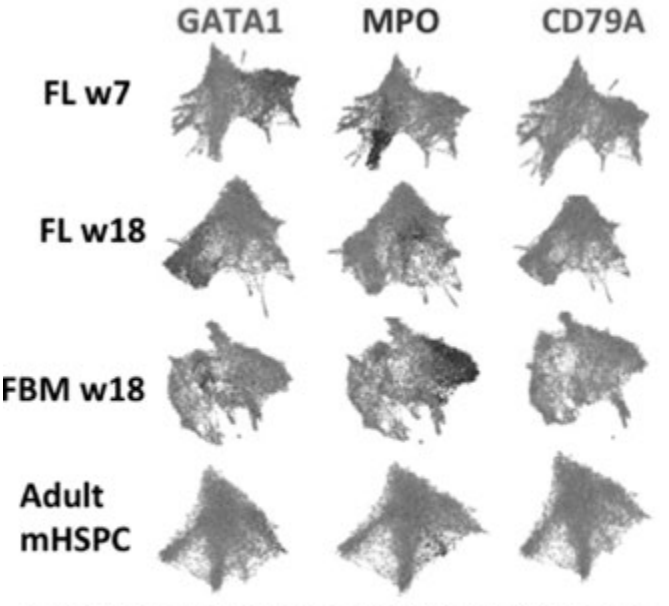

Figure 1. Striking differences in composition HSPC throughout ontogeny. Representative KNN graphs show differentiation trajectories of Lin-CD34+ cells from 1st trimester fetal liver (FL,week 7) week, matched 2nd trimester FL and fetal bone marrow (w18) and adult mobilised HSPC. *GATA1 (red); MPO* (blue) and *CD79A* (green) are shown to illustrate mega-erythroid, myeloid and B lymphoid differentiation trajectories.

DEVELOPMENT OF A FLUORESCENCE IN-SITU HYBRIDIZATION PROBE FOR DETECTING IKZF1 DELETION MUTATIONS IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

J. Hashiguchi[1,*], M. Onozawa[1], S. Oguri[2], S. Fujisawa[2], M. Tsuji[3], K. Okada[1], M. Nakagawa[1], D. Hashimoto[1], K. Kahata[1], T. Kondo[1], C. Shimizu[2], T. Teshima[1]

[1]Department of Hematology, Hokkaido University Faculty of Medicine, [2]Division of Laboratory and Transfusion Medicine, Hokkaido University Hospital, [3]Chromosome science lab, Sapporo, Hokkaido, Japan

Background: Intragenic interstitial deletion of *IKZF1* is a recurrent genomic alteration in B-cell acute lymphoblastic leukemia (B-ALL). The deletions are mediated by illegitimate V(D)J recombination via cryptic recombination signal sequences (RSSs). There were 4 major types of *IKZF1* deletion (Δ4-7, Δ2-7, Δ4-8, Δ2-8). The presence of *IKZF1* mutation has been reported to be an independent risk factor of poor prognosis for patients with B-ALL. Despite the prognostic value, there are no suitable testing methods for detecting the mutation, and current clinical applications are therefore limited.
Aims: To detect various type of *IKZF1* deletion including the commonly deleted exon 4-7 region, we developed a fluorescence in-situ hybridization (FISH) probe set. We validated the probes using clinical samples.
Methods: The probe set consists of a designed probe for the commonly deleted region (Cy3, red) and a bacterial artificial chromosomes (BAC) clone probe for detecting the 3' flanking region (Spectrum Green; RP11-248J17). The *IKZF1* commonly deleted region was amplified using long PCR method. Normal cutoff was validated using 10 peripheral blood samples from normal individuals. Twenty-three clinical samples (9 Ph(+)ALL, 8 Ph(-)ALL, 3 CML lymphoid crisis, 3 AML) were analyzed using the probe. *IKZF1* deletion was also validated by multiplex PCR method and each deletion joint was sequence verified.

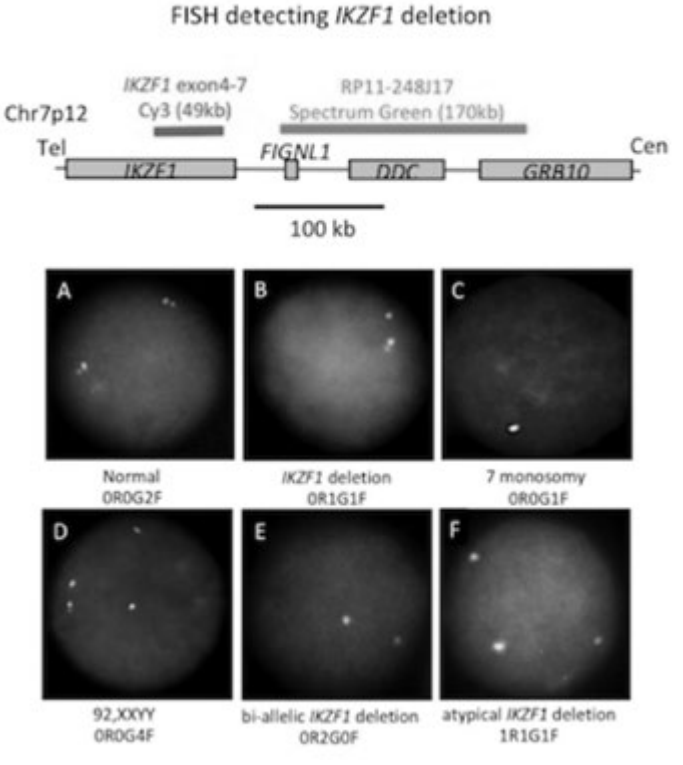

Figure 1.

Results: Normal cell showed 2 fusion signal reflecting intact *IKZF1* alleles (0R0G2F). In the cell with heterozygous *IKZF1* deletion, intact *IKZF1* allele showed a fusion signal, and the deleted allele showed loss of the red signal (0R1G1F). Normal cutoff value for *IKZF1* deletion was established to be 1.5% from 10 normal samples. Gain or loss of entire IKZF1 region was detected by gain or loss of fusion signal such as 0R0G4F or 0R0G1F. Intragenic *IKZF1* deletion was frequent in Ph(+)ALL (7/9, 77.8%) but relatively rare in Ph(-)ALL (3/8, 37.5%) and CML lymphoid crisis (1/3, 33.3%). On the other hand, *IKZF1* deletion was not detected in any of the AML samples. For the cases with *IKZF1* deletion, the exact deletion type could be identified by multiplex PCR in all cases. The joint sequence was unique to each patient showing a typical RAG1/2-mediated V(D)J recombination signature. One case showed 2 *IKZF1* deletion signals in each cell (0R2G0F). Multiplex PCR verified 2 independent deletion (Δ, 2-7 Δ4-8) in the case. One case showed an atypical break-apart signal (1R1G1F). Inverse PCR of the case revealed insertion of the deleted *IKZF1* fragment into a legitimate RSSs site at immunoglobulin kappa on chromosome 2. This is the first description showing that the insertion of a RAG1/2-mediated fragment can occur between genuine and cryptic RSSs in ALL. RAG1/2-mediated genome exchange could play a role in leukemogenesis by causing cancer-associated insertion that results in disruption of the expression of a tumor suppressor.
Summary/Conclusion: In this study, we established FISH probes detecting *IKZF1* deletion in a quick, quantitative and cost-effective manner. FISH based assay provided a novel insight into B-cell receptor editing by insertion of a cryptic RSS-mediated genomic fragment in ALL biology.

PB1596

PHOTOLUMINESCENT ZINC OXIDE NANORODS-A NEW TOOL FOR DETECTION OF HUMAN LEUKEMIC CELLS

Y. Harmaza[1,*], A. Tamashevski[1], R. Viter[2], E. Slobozhanina[1]

[1]Laboratory of medical biophysics, Institute of biophysics and cell engineering, Minsk, Belarus, [2]Institute of Atomic Physics and Spectroscopy, University of Latvia, Riga, Latvia

Background: Traditional methods of diagnostic of hematologic cancers (flow cytometer, immunohistochemistry analysis, etc.) have a high sensitivity and specificity, but they require expensive equipment and specially trained staff, which increase the costs of these analysis. Therefore, the actual task is to develop a new tool-diagnostic biosensors which are expanding beyond traditional clinical labs to point-of-care and home settings. Nowadays zinc oxide (ZnO)-based nanostructures owing to unique physical properties-high photoluminescence (PL), biocompatibility and other multifunctional characteristics attract attention as building blocks for biosensor development. These properties of ZnO help retain biological activity of the immobilized biomolecule and help in achieving enhanced sensing performance.
Aims: In current work, we demonstrate the possibility of a fluorescent detection of human leukemic cells: T- and B-lymphoblasts, using zinc oxide nanorod (ZnO NR) platforms and immobilized on them specialized monoclonal antibodies (MABs) against cluster of differentiation (CD) proteins on the surface of investigated cancer cells (CD5 and D19).
Methods: It was used human cell lines MOLT-4 derived from the patient with an acute lymphoblastic leukemia in relapse and IM-9 derived from the patient with a multiple myeloma and also healthy human's peripheral mononuclear cells as control samples where expression of CD5 and CD19 antigens were found in 8-12% and 5-9% of the cell population, respectively. For platform preparation, glass substrate was cleaned in ethanol and mQ and treated by the use of plasma technology; than ZnO NRs stock solution was dropped on it and annealed at 300°C.
Results: Firstly, we established the optimal concentrations of human anti-CD19 and anti-CD5 and their isotype controls (mouse anti-human IgG1 and IgG2a) for immune biosensor development, *i.e.* an appropriate amount of MABs to provide significant coverage of the ZnO NRs surface and maximum response of ZnO NRs photoluminescence. Next, it was shown that B- or T-lymphoblastoid cells bind to CD19 or CD5 targered ZnO NRs with high selectivity and PL signal increased on 50–70% in comparison with the signal from the control samples. Furthermore, rise of the ZnO NRs photoluminescence intensity correlated with the amount of CD19+ and CD5+ cells in the investigated populations (controlled using flow cytometry).
Summary/Conclusion: The outcomes of our study confirmed that ZnO NRs exhibit an optical property useful for effective monitoring of fluorescent signal from biological systems: human leukemic lymphocytes conjugated with CD19 or CD5 MABs, even at extremely low cell concentrations-from 5-10 till 250 cells per 1 mm^2 of ZnO NRs platform. We propose that MABs-targeted ZnO NRs can be used for the development of biosensors for detection of human leukemic cells.
This work has received funding from the European Union's Horizon 2020 research and innovation programme H2020-MSCA-RISE under grant agreement 777926.

THE VR-ALL LINE: A NOTCH MUTANT MODEL FOR B-ALL

P. Takam Kamga[1,2,*], G. Dal Collo[2], G. Bassi[2], M. Midolo[2,] M. Delledonne[3], M. Chilosi[4], M. Bonifacio[2], M. Krampera[2]

[1]Academie de Versailles, Versailles, France, [2]Medicine, [3]Biotechnology, [4]Department of Diagnostics and Public Health, University of Verona, Verona, Italy

Background: Notch signaling contribution to B-cell acute lymphoblastic leukemia (B-ALL) development is still under investigation. The serendipitous onset of B-ALL in a patient affected by the germinal Notch mutation-dependent Alagille syndrome allowed us to establish a B-ALL cell line (VR-ALL) bearing a genetic loss of function in components of Notch signaling.
Aims: We used the VR-ALL cell line in comparison with two other B-ALL lines (RS4;11 and SUB-P15) and primary samples from B-ALL patients to analyze the contribution of defective notch signaling in B-ALL cell lines as well as cell line based-xenograft models of B-ALL.
Methods: B-ALL cell lines were obtained from ATCC, while B-ALL primary cells were obtained from bone marrow or peripheral blood of 30 B-ALL patients. Flow cytometry and western immunoblotting were used to study the expression of Notch receptors and ligands. Drugs used were Cytarabine, Dexamethasone and Doxorubicin alone or in combination with gamma secretase inhibitors (GSIs). Mice xenograft model of B-ALL were obtained by injecting the B-ALL line RS4;11 in NOD/Shi-scid/IL-2Rγnull mice (NOG). Cell viability was evaluated by Annexin-V/PI and MTT assay; proliferation was assessed through CFSE dilution.
Results: Flow cytometry analysis and May-Grünwald Giemsa staining revealed that the VR-ALL was a Pre-B-ALL cell line. Similarly, to RS4;11 and SUP-B15 cell lines, VR-ALL cells grew easily in RPMI or IMDM supplemented with 10% FBS. Western blot and flow cytometry analysis showed that VR-ALL cells as well as primary blast cells displayed a Notch expression pattern consisting in lower expression levels of Notch2 and Jagged1, high expression levels of Notch1, Notch3, Notch4, Jagged2, DLL3 and DLL4. But in contrary to SUP-B15 and RS4;11, the Notch target Hes1 was absent in VR-ALL cells. However, VR-ALL cells were still highly sensitive *in vitro* to GSI XII as shown by MTS and Annexin assays. Then, we successfully obtained a mice xenograft model of B-ALL with high bone marrow leukemic burden, by injecting the VR-ALL cell line in NOD/Shi-scid/IL-2Rγnull mice. Concordantly with *in vitro* observation, administration of GSI-XII to mice, significantly lowered the leukemic burden in the bone marrow. These activities of GSI-XII in cells with a defective Notch activity suggested a Notch-independent role of gamma secretase inhibitors. Seeking the influence of Notch status on drug response, we observed that the treatment of the cell lines *in vitro* with Cytarabine, Dexamethasone or Doxorubicin induced a dose-dependent decrease in VR-ALL cell viability. Noteworthy, VR-ALL cells were less sensitive to the treatment with glucocorticoids than the two other B-ALL cell lines. This reduction was abrogated when the glucocorticoid was associated to GSI-XII.
Summary/Conclusion: Through this study we propose a new cell line that has allowed us to understand B-ALL pathogenesis, representing an appropriate tool to better unravel the mechanistic role of Notch signaling in B-ALL. Moreover, VR-ALL could be a valuable tool to investigate the mechanisms of B-ALL relapse determined by glucocorticoid refractoriness.

DOWNREGULATION OF CDKN2B EXPRESSION DUE TO DELETION OR HYPERMETHYLATION IN T-ACUTE LYMPHOBLASTIC LEUKEMIA

A. Kwon[1,*], H. Choi[1], J. Kim[1], M. Kim[1,2], Y. Kim[1,2]

[1]Catholic Genetic Laboratory Center, [2]Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: T-acute lymphoblastic leukemia (T-ALL) is an aggressive hematologic malignancy that accounts for approximately 20% of all cases of ALL. It tends to be more common in adults than children.Understanding the disease pathogenesis and expected biological behavior of T-ALL on the basis of genetic profiles is essential if T-ALLis to be successfully treated.
Aims: In this study, we explored the association of pathogenesis and biology based on genetic aberrations in T-ALLbyintegrative genetic analyses using massive parallel sequencing as well as copy number analysis of T-ALL patients.
Methods: The study included 102 T-ALL patients (69 male and 33 females comprising 42 children and 60 adults. Massive parallel sequencing of the exons of 11 genes (*NOTCH1*, *DNMT3A*, *FBXW7*, *RUNX1*, *PHF6*, *PTEN*, *GATA3*, *KRAS*, *EZH2*, *NRAS*, and *SH2B3*) was performed to comprehensively characterize the patterns ofsomatic mutations in T-ALL. Multiplex ligation-dependent probe amplification (MLPA) was done for detection of commonly deleted genes in T-ALL.In addition, *CDKN2A* and *CDKN2B* mRNA expressionand promoter methylation were analyzed usingRT-qPCRand pyrosequencing, respectively.
Results: We identified principal genetic alterations in 97.1%(99/102) cases of T-ALL using integrativegenetic analyses including massive parallel sequencing and MLPA. A total of 134 mutations were found in descending order of genes: *NOTCH1*(66.7%), *FBXW7*(19.6%), *PHF6*(15.7%), *RUNX1*(12.7%), *NRAS*(10.8%), and *DNMT3A*(9.8%).Copy number alterations were most frequently detected *CDKN2B*,*CDKN2A* and genes on 9p21.3 in T-ALL(45.1%). Gene expression data demonstratedthe downregulation of *CDKN2B* in most cases of T-ALL, while *CDKN2A* downregulation was mainly restricted to deletions. Additional quantitative methylation analysis demonstrated that *CDKN2B* downregulation stemmed from deletion and hypermethylation. Analysis of 64 patients with *CDKN2B* hypermethylation indicated relationships with older age of onset and early T-cell precursor ALL, which involved very early arrest of T-cell differentiation. Genes associated with methylation and myeloid neoplasms including *DNMT3A* and *NRAS* were more commonly mutated in T-ALL with *CDKN2B*hypermethylation. Especially, *CDKN2B*biallelic deletion or high methylationlevel(≥45%) was a poor prognostic factor, as was age of onset, *GATA3* and *SH2B3* mutations.
Summary/Conclusion: This study clarifies one of the most important genetic events in T-ALL, *CDKN2B* downregulation, via the mechanisms of deletion and hypermethylation. Different susceptible genetic backgrounds exist according to *CDKN2B* downregulation mechanism.

CRISPR/CAS9 SYSTEM IS ABLE TO TURN ETV6/RUNX1 EXPRESSION OFF IN ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

A. Montaño[1,*], V. Alonso-Pérez[1], J.L. Ordoñez[1], A. Marin-Quilez[1,] M. Quijada[1], A. Martín-Martín[1], M. Herrero-García[2], M. Sánchez-Martín[2], R. Benito Sánchez[1], J.M. Hernández-Rivas[1], I. García-tuñon[1]

[1]Molecular genetics in onco-hematology Research Group, Institute for Biomedical Research of University of Salamanca (IBSAL)-University of Salamanca, [2]Servicio de Transgénesis, Nucleus, Universidad de Salamanca., Salamanca, Spain

Background: Acute lymphoblastic leukemia (ALL) is the most common cancer in childhood, around 75% of ALL occurs in children under 6 years. In spite of survival rate has increased over the last years, about 20% of patients continue to relapse. These cases are associated with a worse outcome, even in those genetic subtypes considered to have a good prognosis, such as the t (12.21) that fuses the *ETV6/RUNX1* (*TEL/AML1*) genes. *ETV6/RUNX1* gene fusion as even initiating in the acquisition of leukemic phenotype has been demonstrated. However, its function in the pathology development and maintenance is still unclear. Several studies suggest that *ETV6/RUNX1* promotes tumor survival through up- regulation of anti-apoptotic members of *BCL-2* family protein. In this study, we evaluated the ability of CRISPR/Cas9 genome editing system to eliminate the expression of *ETV6/RUNX1*, and therefore its effect on the expression of anti-apoptotic proteins.
Aims: To abrogate *ETV6/RUNX1* expression by CRISPR/Cas9 technology in the REH cell line.
Methods: The REH cell line (DSMZ), from LAL and expressing the *ETV6/RUNX1* fusion protein, was used. Based on the methodology of CRISPR/Cas9, sgRNAs directed towards the end of exon 5 of *ETV6*, were designed with the intention of producing indels that modify the ORF of the oncogene, and, therefore, the expression of the protein. These sgRNAs were cloned into a vector containing the Cas9 nuclease coding sequence and then were electroporated into the REH cells. The edition of the *ETV6/RUNX1* coding sequence was checked by PCR and Sanger sequencing. Single-edited cell derived cell lines were established to check *ETV6/RUNX1* mRNA expression and downstream targets expression such as *BCL-2* by qPCR and Western Blot. Two single-edited cell clones with wt *ETV6/RUNX1* sequence were used as controls.
Results: The *ETV6/RUNX1* coding sequence in the REH cell line through the CRISPR/Cas9 system was successfully edited. The edition resulted in several frameshift mutations as insertions and deletions that modified the ORF of the oncogene, as well as a deletion between both sgRNAs. Two single-edited cell clones carrying a deletion and another with an insertion were selected. *In silico* analysis of their sequence reveal the generation of KO alleles in all of them. All single-edited clones showed a reduction up to 99,9% of mRNA level compared with REH parental cell line, showing an efficient abrogation of *ETV6/RUNX1* expression. To evaluate the effects of lack of oncoprotein expression in REH cell, we assessed the expression level of *BCL-2* family member proteins. A decreased expression of *BCL-2* and *BCL-XL* in all *ETV6/RUNX1* KO clones compared with parental and control

cell lines we observed, which demonstrates the reduction of the oncogenic potential of these cells.
Summary/Conclusion: For the first time, the CRISPR/Cas9 system to edit the sequence of *ETV6/RUNX1* oncogene was using, inducing frameshift mutations, and leading to the eradication of the fusion product. The lack of *ETV6/RUNX1* expression prevents pro-tumoral effects, such apoptosis suppression through *BCL-2* family proteins overexpression. The use of CRISPR/Cas9 technology could be a promising new therapeutic option for ALL patients. Bone marrow leukemic stem cells could be edited by CRISPR-Cas9 technology to truncate *ETV6/RUNX1* fusions, and truncated cells specifically selected to transplantation treatment.

THE EXPRESSION OF THE HISTONE METHYLTRANSFERASE G9A CORRELATES WITH VLA-4 INTEGRIN IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

E. Madrazo[1], D. Ruano[2], C. Sánchez-Valdepeñas[2], Á. González-Murillo[2], L. Abad[2], M. Ramírez[2], J. Redondo-Muñoz[1,*]

[1]Universidad Complutense, [2]Hospital Universitario Niño Jesús, Madrid, Spain

Background: Acute lymphoblastic leukemia (ALL) comprises a group of aggressive and heterogeneous malignancies, occurring in adults and representing the most common pediatric cancer. Up to 25% of patients are genetically unclassified or have an intermediate prognosis; therefore, identifying novel biomarkers and therapeutic targets, as genetic and epigenetic changes, is critical to accurately allocate patients in risk groups. Epigenetic enzymes represent novel therapeutic targets in acute leukemia; however, their connections with prognosis markers across children or adult ALL patients remain unclear
Aims: In this study, we described that the expression of G9A correlates with VLA-4 (very late antigen-4), an integrin cell receptor that serves as a central mediator for the dissemination of ALL cells and as prognostic predictor in pediatric ALL.
Methods: We analyzed the expression of G9A, VLA-4 and SUV39H1 in 51 children patients (range 1-14 years) by RT-qPCR. Then we evaluated the correlation between the expression levels and clinical characteristics of the cohort. We also analyzed the cell migration by using *in vitro* Transwell experiments.
Results: We demonstrated a positive correlation between VLA-4 and G9A levels but not between VLA-4 and SUV39H1. Remarkably, we did not observe any VLA-4/G9A correlation in normal lymphocytes (n=10), suggesting a fundamental connection in leukemia cells. To determine the role of G9A in ALL cell migration, we quantified the levels of H3K9me3 during ALL cell migration. Effective migration induced higher levels of H3K9me3 in moving cells compared to their counterpart in the upper chamber of the Transwell. Moreover, BIX01294 treatment (a G9A inhibitor) impaired the ALL cell migration, suggesting a critical role for this enzyme during leukemia dissemination.
Summary/Conclusion: In summary, our results suggested a clinical potential interest of G9A, as its correlation with VLA-4 might open future targeting approaches and innovative drugs for children ALL patients.

ABNORMAL EXPRESSION OF RAS RELATED DEXAMETHASONE INDUCED 1 (RASD1) IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

R.-Q. Lu[1,*], L.-X. Wu[1], Y.-L. Zhou[1], J.-L. Li[1], H. Jiang[1], B. Jiang[1], Q. Jiang[1], X.-H. Zhang[1], L.-P. Xu[1], K.-Y. Liu[1], G.-R. Ruan[1], X.-J. Huang[1,2]

[1]Peking University People's Hospital, Peking University Institute of Hematology, [2]Peking-Tsinghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Peking University, Beijing, China

Background: Relapse remains the major cause of treatment failure in adults with B-cell acute lymphoblastic leukemia (ALL) achieving complete remission after induction therapy. Identifying new biomarkers in B-cell ALL and studying their clinical significance and biological function will be helpful for risk-stratification, treatment decision and targeted therapy. RASD1 (ras related dexamethasone induced 1) maps to chromosome sub-band 17p11.2, which encodes a member of the Ras superfamily of small GTPases. The role of RASD1 in cancer remains controversial. In our previously conducted bio-informatics analyses of transcriptomic data to identify mRNA transcripts aberrantly-expressed in B-cell ALL, RASD1 was identified as one of most differentially expressed genes which were up-regulated in B-cell ALL. However, the expression and biological function of RASD1 remain unknown in B-cell ALL.
Aims: To investigate the expression level of human RASD1 messenger RNA in B-cell ALL by real-time fluorescent quantitative reverse transcription-polymerase chain reaction assay.
Methods: A real-time quantitative RT-PCR based on TaqMan fluorescence methodology was used to examine RASD1 expression in 11 malignant hematological disorders cell lines and bone marrow samples from 158 adults with B-cell ALL and 40 healthy donors.
Results: Results showed that RASD1 gene expression was higher in cell lines from B-cell ALL (Sup-B15, BV-173), but nearly undetectable in cell lines derived from AML(KG-1, NB4, HL60, OCI-AML2), CML(K562), T-ALL(MOLT4, 6T-CEM), lympoma(Ramos, Raji) and Epstein-Barr virus-transformed lymphoblastoid cell lines (EBV-LCL)(Fig.1A). The relative levels of RASD1 gene expression in marrow from the 158 newly diagnosed B-cell ALL (median 80.12%; range 0.17-2822.33%) were significantly higher than those of marrow from the 40 healthy donors(median 7.59%; range 0.46-38.66%, $p<0.0001$, Fig.1B). The median level of RASD1 in 158 newly diagnosed patients was 80.12%, while the median level in 214 treated patients who achieved complete remission decreased to 3.71%. However, in 17 relapsed patients and 4 refractory patients, the median level was 47.29% and 29.01%, respectively(Fig.1B). In newly diagnosed B-cell ALL, 4 patients with MLL-AF4 translocation showed lower RASD1 expression compared with 68 patients without this translocation ($p=0.005$). RASD1 expression levels were not significantly associated with initial white blood cell counts, hemoglobin, and platelet counts in the peripheral blood, blast in the bone marrow, age, sex, prognosis grouping, immunophenotype, BCR-ABL fusion gene and IKZF1 deletion ($p>0.05$).

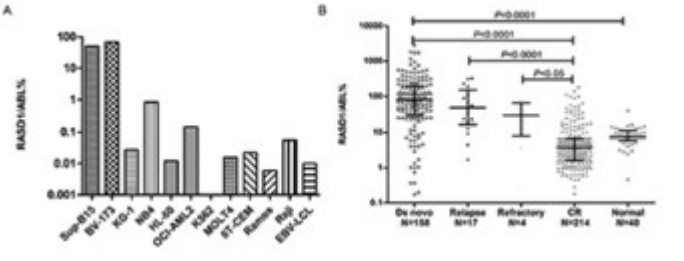

Figure 1. Levels of RASD1 expression in (A) leukemic cell lines; (B) de novo, relapsed, refractory and complete remission (CR) B-cell ALL and normal bone marrow.

Summary/Conclusion: These findings suggest that RASD1 was widely over-expressed in adults with B-cell ALL and that abnormal expression of RASD1 in leukemia may be involved in the pathomechanism of B-cell ALL.

PB1602

CD45 SURFACE EXPRESSION AS A PROGNOSTIC FACTOR IN CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA

V. Antari[1,*], E. Vasileiou[1], A. Tragiannidis[1], E. Gounari[2], E. Hatzipantelis[1], V. Tsavdaridou[2], T. Anastasiou[3], T. Papageorgiou[1], A. Giannopoulos[1]

[1]Hematology Oncology Unit, Pediatric Department of Aristotle University of Thessaloniki, [2]Immunology Department, Microbiology Laboratory, AHEPA General Hospital, Thessaloniki, Greece, Thessaloniki, [3]Hematology Laboratory, Children's Hospital P. & A. Kyriakou, Athens, Greece

Background: CD45 antigen, also known as Protein Tyrosine Phosphatase, receptor type, C (PTPRC), is expressed in hematopoietic cells and its expression is commonly quantified at diagnostic immunophenotyping. Overexpression of CD45 has been previously linked to poor prognosis in children with B- and T-cell ALL.
Aims: Our goal is to study the possible use of CD45 expression as a prognostic factor.
Methods: Bone marrow samples of children with B-cell ALL were studied at the time of diagnosis before treatment initiation according to ALL-BFM 2009. All patients that were admitted to our department from April 2013 to October 2017 were enrolled in the study (44 patients in total). CD45 expression was measured both in normal lymphocytes and leukemic blasts and a relative ratio of its expression (leukemic *versus* normal) was calculated. Statistical analysis was conducted with the Statistical Package for the Social Science (SPSS) for Windows, version 23 (SPSS Inc., Chicago, IL).
Results: We divided the sample into two groups according to the cell line affected (B- and T-cell leukemia). In our study group 39 children were diagnosed with B-ALL and only 5 with T-ALL. The expression of CD45 was

assumed to be high when it exceeded the 75th percentile (relative ratio 12.4% for B-ALL). It was observed that the mean expression of CD45 in patients with B-ALL who had a relapse or died than in patients without an event was higher (Figure 1). We also found that there is a statistically important correlation between relapse or death and the expression of CD45 above the 75th percentile in patients with B-ALL, p<0.05 (p=0.011). Moreover, we calculated that the probability of an event (relapse or death) in patients with B-ALL was 18.67 times higher when the expression of CD45 was above the 75th percentile. Finally, patients with B-ALL and high expression of CD45 had a shorter 2-year event-free survival compared to patients with low expression (51.4% *versus* 96.6%, p<0.01). Due to the small sample of patients with T-ALL we could not calculate statistically important correlations in that group.

Summary/Conclusion: The high expression of CD45 could be used as a prognostic factor in patients with acute lymphoblastic leukemia.

PB1603

FXCYCLE BASED PLOIDY CORRELATES WITH CYTOGENETIC PLOIDY IN BCP-ALL AND IS ABLE TO DETECT THE HYPER-DIPLOID MRD CLONE

N. Gupta[1,*], N. Arora[2], M. Parihar[3], S. Banerjee[1], S. Brahma[1], R. Pawar[1], A. Rath[1], S. Shewale[1], S. Krishnan[4], M. Chandy[5], D.K. Mishra[2]

[1]Laboratory Hematology, [2]Molecular Pathology and Laboratory Hematology, [3]Cytogenetics and Laboratory Hematology, [4]Pediatric Oncology, [5]Clinical Hematology, Tata Medical Center Kolkata, Kolkata, India

Background: Flow cytometry (FCM) is a simple technique that can accurately determine DNA ploidy in B-cell precursor ALL (BCP-ALL).

Aims: We tried to analyze the applicability of FxCycle™ based DNA ploidy analysis in risk stratification of BCP ALLs at diagnosis. We also tried to assess the utility of FCM ploidy for monitoring Minimal Residual Disease (MRD) during follow-up.

Methods: A prospective FCM DNA ploidy analysis using FxCycle™ Violet dye was done in 125 consecutive new cases of BCP-ALL from May 2016 to July 2017. The FCM DNA Index (DI) was compared with karyotyping/FISH data wherever available. As a pilot study, in 16 MRD positive cases (n=6 with hyperdiploid diagnostic DI and n=10 diploid diagnostic DI), DNA ploidy based MRD analysis was also performed.

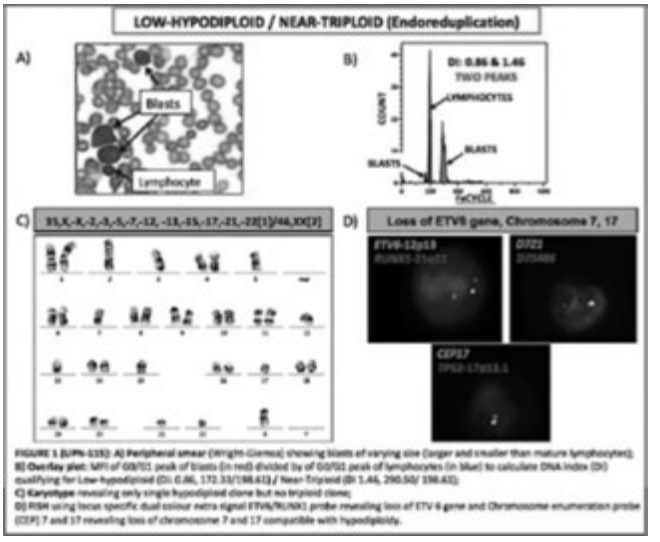

Figure 1.

Results: Of the total 125 cases (age range 10 months-66 years, M:F ratio 1.7:1), n=90 (72%) were pediatric (aged ≤15 years). Karyotype was available in n=119 cases (with 77.3% success rate). Overall cytogenetic ploidy was assessed by both karyotyping and FISH in n=81 cases, only karyotype in n=11 cases and only FISH in n=33 cases. Flow ploidy analysis revealed diploidy (DI 0.96-1.05) in 56/125 (44.8%), low-hyperdiploidy (DI 1.06 to 1.15) in 17/125 (13.6%), high-hyperdiploidy (DI 1.16-1.39) in 41/125 (32.8%) and near-tetraploidy (DI ≥1.80) in 3/125 (2.4%) cases. The high-risk sub-group (Figure 1) of Low-Hypodiploidy (DI 0.70 to 0.88) / Near-triploidy (DI 1.40 to 1.79) (*i.e.* endoreduplication) was seen in n=7 (5.6%) cases while one single case had near haploidy (DI 0.58) with modal chromosome number (MN) 25. Of the 56 cases with diploid DI, successful karyotype was available in n=39 cases of which 10/39 (25.6%) were classic diploids (46, XX or 46, XY) while 29/39 (74.4%) were pseudo-diploids having additional balanced / un-balanced translocations or structural chromosomal abnormalities. Of the n=17 low hyperdiploid DI cases, n=7 cases were concordant with cytogenetic ploidy (MN 47-50 and/ or by FISH) while n=7 cases had MN >50 fitting with description of low DNA index high hyperdiploid subtype (LDI-HHD). Of the n=41 high-hyperdiploid DI cases (karyotype available in n=29 cases), n=26 cases had MN 51-65 (FISH concordant), while in n=15 cases FISH alone confirmed high-hyperdiploidy. DNA ploidy (DI of hematogones 0.96-1.05) could confirm the residual hyperdiploid clone in n=6/6 hyperdiploid MRD positive cases tested.

Summary/Conclusion: FxCycle based DNA ploidy analysis is simple, sensitive and specific technique, which is complementary to cytogenetics in the diagnosis as well as follow-up of BCP-ALLs.

PB1604

CREB KNOCKDOWN INHIBITS GROWTH AND INDUCES APOPTOSIS IN PRE-B ACUTE LYMPHOBLASTIC LEUKEMIA CELLS WITHOUT HAVING A ROLE IN RESTORATION OF CAMP-INDUCED P53 DESTABILIZATION

R. Manafi[1,*], M. Safa[1], F. Alikarami[1], A. Kazemi[1], M. Banan[2]

[1]Iran University of Medical Science, [2]bGenetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Tehran, Iran, Islamic Republic Of

Background: The second messenger cAMP plays key roles in multiple intracellular signaling pathways. cAMP signaling pathway can impede drug-induced apoptosis in leukemic cells and elevated levels of this second messenger inhibit doxorubicin-induced apoptosis and p53 accumulation in acute lymphoblastic leukemia cells. In addition, elevated cAMP levels may activate a variety of signaling pathways through protein kinases. cAMP responsive element binding protein (CREB) is a transcription factor that can be activated by cAMP-dependent protein kinase A. CREB is overexpressed in majority of bone marrow samples from patients with ALL and AML and confers survival advantage to the cancer cells.

Aims: According to the fact that cAMP can activate CREB and the role of CREB in malignant cell growth, we sought to determine if CREB plays the mediator role in inhibitory effect of cAMP on doxorubicin-induced apoptosis and p53 accumulation in BCP-ALL cells or not. Moreover, we aimed to assess the effect of CREB on BCP-ALL, NALM-6 cells proliferation and survival.

Methods: In present study, CREB was knocked down using lentiviral CREB shRNA in NALM-6 cells. Knocked down cells were treated with doxorubicin in presence or absence of the cAMP-elevating agents. The expression levels of different apoptotic and anti-apoptotic proteins were assessed by western blot analysis. Gene expression levels were evaluated using qRT-PCR. The apoptosis was assessed using flowcytometry analysis.

Results: We demonstrated here that CREB knockdown induced apoptosis and impaired growth of BCP-ALL NALM-6 cells which was associated with caspase activation. The gene expression levels of prosurvival signals Bcl-2, Mcl-1, Bcl-xL, survivin and XIAP were down-regulated upon CREB suppression. However, the p53 and p21 levels remain unchanged in CREB knocked down cells. Amazingly, our results showed that CREB knockdown cannot eliminate the inhibitory effect of elevated cAMP on doxorubicin-induced apoptosis and p53 accumulation in BCP-ALL cells.

Summary/Conclusion: These findings indicate a critical role for CREB in proliferation, survival, and apoptosis of BCP-ALL cells. The data also suggest that targeting CREB alone could possibly serve as potential therapeutic approach in BCP-ALL but it cannot restore the doxorubicin-induced apoptosis and p53 accumulation in malignant cAMP-elevated cells.

PB1605

MINIMAL RESIDUAL DISEASE (MRD) MONITORING AND IKZF1/NRAS MUTATION STATUS IN ADULT PH-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) PATIENTS TREATED IN RUSSIAN MULTICENTER STUDY "RALL-2016"

O. Gavrilina[1,*], E. Parovichnikova[1], V. Troitskaya[1], G. Baskhaeva[1], K. Zarubina[1], B. Biderman[1], I. Galtseva[1], Y. Davydova[1], S. Kulikov[1], T. Obukhova[1], A. Sokolov[1], V. Savchenko[1]

[1]National Research Center for Hematology, Moscow, Russian Federation

Background: MRD-tailored therapy based on pediatric-inspired intensification is a back-bone of the majority of the European study groups in adult

ALL. Up to 50-70% of patients from the high risk group defined by specific molecular markers and MRD persistence are being now transplanted from allogeneic donors. The aim of the RALL-study group was to create the protocol that could be easily reproduced in any regional center, to reduce toxicity with the preserving high efficacy. The Russian multicenter ALL-2009 trial defined as non-intensive but non-interruptive approach was conducted since Apr 2009 till Dec 2016 and included 330 Ph-negative ALL pts. OS and disease-free survival (DFS) at 7-years constituted 54,7% and 57% for BCP-ALL and 61% and 68% for T-ALL, respectively. Since Dec 2016 were started new protocol RALL-2016 that based on results of previously ALL-2009 protocol.
Aims: To evaluate the frequency of MRD-persistence and impact IKZF1/NRAS mutation status in patients with d*e novo* acute lymphoblastic leukemia treated by RALL-2016 protocol.
Methods: Taking in consideration the major pitfalls of RALL-2009 (high CR death rate, early CNS relapses in T-ALL, selection in autoHSCT *vs* chemotherapy comparison, absence of MRD monitoring) we developed a new RALL-2016 protocol. One day high-dose MTX and high-dose ARA-C blocks were eliminated and substituted by 2 months of non-interruptive therapy, L-asparaginase was scheduled for 1 year of treatment instead of 2,5y, 15 intrathecal injections were increased up to 21 mostly while consolidation phase, CR T-ALL pts were brought to randomization after the informed consent: autoHSCT *vs* no autoHSCT, with the similar further maintenance. All primary bone samples are collected and tested for cytogenetics and molecular markers, all included pts are MRD monitored by flow cytometry in a centralized lab. Since Dec 2016 till Feb 2018 56 adult Ph-negative ALL pts from 5 centers were included in RALL-2016 protocol: median age 35 y (18-54) (BCP-ALL-34(62%) pts, T-ALL-19(34%), biphenotypic-2(4%).
Results: Induction results are evaluable in 53 pts: 44(83%) achieved CR, 5 died during induction (9%), 4(8%) was resistant. 15 patients with T-ALL after CR achievement were randomized for chemotherapy or autoHSCT: 7 and 8 pts, respectively. So far 5 of 8 T-ALL pts were transplanted at a median time of 6 months of CR. Long-term results will come in some years. MRD was detected in 14 (48%) out of 29 B ALL pts, in 1 (8%) out of 13 T-ALL pts and in 1 out of 2 biphenotypic pts on +70 protocol day (end of induction). MRD testing was performed in 27 B ALL patients and 13 T ALL patients on +133 and +190 protocol day. All T ALL patients were MRD negative. 8 (30%) and 7(26%) out of 27 B ALL patients were MRD positive on +133 and +190 protocol day, respectively.We estimated IKZF1 and NRAS mutation status in 17 pts with B-ALL. We detected IKZF1 and NRAS mutations in 3 (18%) different pts for both. All 3 pts with IKZF1 mutations were MRD-positive on day +70 (2 in CR and 1 with refractory disease). Only 1 pts (with refractory disease) was MRD-positive on day +70 with NRAS mutation, another 2 pts with NRAS mutation were MRD-negative.

Table 1.

B-ALL
MRD persistence and IKZF1, NRAS mutation status

Status	Pts with/without mutations		MRD status +70 day of protocol (end of induction)		
			MRD-positive	MRD-negative	Refractory disease
IKZF1	with mutation	3 из 17 (18%)	2 из 3 (67%)	0 из 3 (0%)	1 из 3 (33%)
	without mutation	14 из 17 (82%)	5 из 14 (36%)	7 из 14 (50%)	1 из 14 (7%)
NRAS	with mutation	3 из 17 (18%)	0 из 3 (0%)	1 из 3 (33%)	1 из 3 (33%)
	without mutation	14 из 17 (82%)	3 из 9 (33%)	5 из 9 (56%)	1 из 9 (11%)

Summary/Conclusion: MRD was detected more often in B ALL pts than T ALL pts on +70, +133 and +190 days of RALL 2016. Tumor clone decline was identified in B ALL MRD positive patients on +133 comparing to day +70 day. Pts with IKZF1 mutations were characterized MRD persistence after induction. Currently the group of analyzed pts is small and it seems to be reasonable to continue a study of MRD persistence and IKZF1 gene mutation status in pts with B-ALL.

PB1606

LEUKEMIA BY ASSOCIATION: A CASE SERIES OF MARITAL PARTNERS WITH BLOOD CANCERS

T. Nevill*, E. Nevill, M. Power, D. Sanford, M. Barnett, C. Toze
S. Nantel, J. White, Y. Abou Mourad, S. Narayanan, D. Hogge
K. Song, H. Sutherland, D. Forrest, A. Gerrie, R. Broady

Division of Hematology, Leukemia/BMT Program of BC, Vancouver, Canada

Background: Epidemiologic data suggests heritable factors play a minor role in leukemia causation and environmental factors are a major contributor (Lichtenstein, 2000). Exposure to radiation or toxins is linked to the pathogenesis of a variety of blood cancers and husbands and wives may experience similar environmental exposures. Leukemia in marital partners was first reported by Street in 1950 and rare reports since then have postulated a single causative agent including communicable infections (EBV, HTLV-I and HIV; Lynch, 1984). A larger group of affected couples would allow for the evaluation of commonalities and potential etiology.
Aims: To review cases where both marital partners were diagnosed with leukemia to determine patterns and identify common risk factors.
Methods: A retrospective review of patients (pts) presenting to our centre with leukemia between 2012 and 2017 was performed to determine if they previously had a spouse with a leukemia diagnosis. Data collected included basic demographics, diagnosis, order of onset, interval from marriage and between leukemia diagnoses, environmental exposures, comorbidities, family history of malignancy and treatment outcomes.
Results: Between 02/12 and 03/17, 5 pts presented with leukemia (2 ALL, 1 AML, 1 CML and 1 CLL) who had previously had a spouse with leukemia (2 ALL, 1 AML, 1 CML and 1 CLL). Three couples were Caucasian, 1 Asian and 1 South Asian; all marriages were non-consanguineous. None of the 10 pts had a family history of leukemia. Median age at time of first leukemia (L1) (3 wives, 2 husbands) was 44 years (y) (range 29-57) and of second leukemia (L2) was 62 y (range 45-72). None of the couples had the same leukemia subtype. Interval from L1 to L2 was a median of 14.5 y (range 0.8-21). Median duration of marriage at time of L1 was 16 y (range 7-35) and L2 was 27 y (range 17-45). Comorbidities included a prior malignancy in 2 pts (Hodgkin lymphoma and basal cell Ca). Seven pts were lifetime non-smokers; the remaining 3 pts had not smoked for 17-38 yrs. Excessive alcohol intake was seen in only 1 pt; 5 had never consumed alcohol. Five pts had potential occupational toxin exposures (2 health professionals, 1 marine engineer, 1 transportation industry worker and 1 construction worker); one other pt had previously received radiotherapy. Marital partners fell into 2 groups-either both had occupational toxin exposures (3 couples) or neither did (2 couples). The latter group included 2 wives with Ph+ CML whose husbands had ALL with common translocations [t(4;11), t(8;14)]. In both of these couples, the wife had a striking family history of solid tumours. Six of 10 pts are alive — 4 pts after allogeneic SCT, 1 pt with CML who received TKI for 10 y but is off therapy for 2 y without recurrence and 1 pt with CLL who has not yet required therapy. Four pts have died from leukemia progression (2 AML, 2 ALL).
Summary/Conclusion: In a short time period, 5 pts presented to our tertiary care centre with a leukemia having previously had a spouse with leukemia. Specific etiology was difficult to determine in most cases but certain patterns were identified. Leukemia typically developed many years after marriage, L1 at a median of 16 y and L2 at a median of 27 y. Potential occupational exposures were found in both marital partners in 3 cases; in the other 2 partners, the wife developed CML and the husband developed ALL with a classic translocation. This case series significantly adds to the sparse literature on spousal leukemia and suggests that the partner of a pt with leukemia is at increased risk for developing leukemia.

PB1607

MIR-21 REGULATE ADULT B-ALL BY TARGETING CELL CYCLE PROTEIN TLK2

X. Wang*, L. Xia

Union Hospital, Tongji Medical College, Huazhong University of Science & Technology, WuHan, China

Background: ALL remains one of the most challenging adult malignancies with a high recurrence rate and a low cure rate. The main causes of ALL relapse is a severe disturbance of apoptotic pathways occurs.It was reported that mir-21 is significantly increased in patients with B-ALL, however, the biological function of miR-21 in B-ALL remains poorly understood.Cell cycle disorders play an important role in the development of tumor, We used miRanda software to look for possible downstream target genes for miR-21, and found that the cell cycle protein TLK2 3 '-UTR region has a sequence that can be combined with the miR-21 seed region, as well as we found in the Oncomine database that TLK2 has differential expression in B-ALL patients and normal human bone marrow.
Aims: In this study, we detected miR-21 levels in B-ALL cell line (nalm-6) to investigate the mechanism of its oncogenic function.

Methods: First, we compared miR-21 levels of bone marrow mononuclear cells between patients (n=28) and normal control (n=15),Then, to investigate the miR-21expression in vitro, we detected the miR-21 levels in BCP-ALL cell lines Nalm-6 cells. To evaluate whether miR-21 influence the function of Nalm-6 cells, antagomir-21 was used to knockdown miR-21 and antagomir-NC was used as a control. After incubating antagomir-21or antagomir-NC with Nalm-6 cells for 24h, 48h and 72h, we detected the proliferation by Cell Counting Kit-8, and assessed the apoptosis and cell cycle by flow cytomete, western blot was performed to study the expression analysis of Bcl-2, Bax and active caspase-3 proteins.we used miRanda software looking for the downstream target genes of miR-21, and verified the relation of miR-21 and TLK-2, we detected the qPCR and western blot.
Results: The results showed that the relative expression of miR-21 3.328±0.5156 N=18 in the bone marrow of B-ALL patients was significantly higher than that in normal control (1.174+0.1641, N=15), and the difference was statistically significant (P<0.01). The expression of miR-21 in nalm-6 cells was about 3.2 times (P<0.01) the control. The proliferation ability of the nalm-6 transfected with antagomir-21 was significantly inhibited.Compared with the antagomir-nc negative control group, the proliferation ability of nalm-6 decreased in 48 hours (16.5+0.09287)%, and decreased in 72 hours (18.4+0.01479)% (P<0.05 and P<0.001), and the apoptosis rate of nalm-6 cells in the antagomir-21 group was about 2.44 times that of the negative control group (P<0.05). The expression level of bcl-2 protein was positively correlated with miR-21 expression, and miR-21 had no significant effect on Bax expression level.Compared with the control group, the proportion of G1 phase cells (55.75++3.748%) was significantly higher than that in the control group (44.635++1.266%) (P<0.05), while the proportion of S phase cells decreased significantly (41.88+2.630)% and (53.675+0.8132)% (P<0.05).PCR results showed no significantlly change on TLK2 mRNA levels after transfection with antagomir-21 (P<0.05), but western Blot results showed a significant decrease in TLK2 protein expression levels in transfected antagomir-21 group (P<0.05).

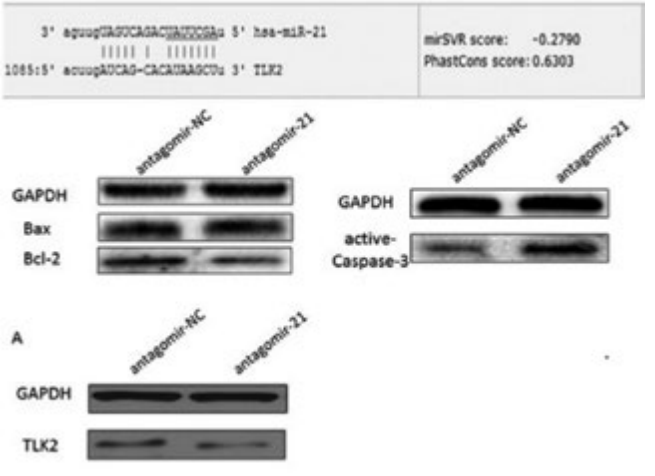

Figure 1.

Summary/Conclusion: Overall, in this work ,For the first time, the novel mechanism of miR-21 regulating cycle was explored in the b-all cell line nalm6, and an interesting relationship between mi21 and cell cycle protein TLK2 was introduced initially, providing new ideas for the oncogene role of miR-21 in B-ALL.

PB1608

PARTHENOLIDE, AN NF-KB INHIBITOR, INDUCE CELL DEATH AND SUPPRESS CELL PROLIFERATION IN LYMPHOID MALIGNANCIES

J. Neves[1], J. Jorge[2,3], R. Alves[2,3], A.C. Gonçalves[2,3], A.B. Sarmento Ribeiro[2,3,4,5,*]

[1]Department of Life Sciences, Faculty of Science and Technology, University of Coimbra, [2]Laboratory of Oncobiology and Hematology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra (FMUC), [3]Coimbra Institute for Clinical and Biomedical Research (iCBR)-Group of Environment Genetics and Oncobiology (CIMAGO), FMUC, [4]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, [5]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Acute Lymphoblastic Leukemias (ALLs) are hematologic malignancies characterized by dysregulated cell proliferation and differentiation arrest, resulting in the accumulation of immature lymphoid progenitors (B or T). Burkitt lymphoma (BL) represents a highly aggressive lymphoma, characterized by acute onset and rapid doubling time. The progress in new therapeutic approaches to treat patients with ALL are scarce, the survival rates have not increased substantially in recent years and relapses are frequent. Playing an important role in the regulation of diverse biological processes such as cell proliferation and survival, nuclear factor kappa B (NF-kB) is closely associated with various human malignancies. Parthenolide (PRT), a sesquiterpene lactone, was reported to inhibit the DNA binding of NF-KB. This compound induces apoptotic cell death by multiple pathways, including oxidative stress, endoplasmic reticulum stress, intracellular thiol depletion, caspase activation, and mitochondrial dysfunction, as well as sensitizes cancer cells to chemotherapeutic drugs.
Aims: In this context, this work aimed to evaluate the therapeutic potential of PRT on ALL and BL cell lines and characterize the type of cell death induced and its molecular mechanisms.
Methods: To this end, T-ALL (CEM, JURKAT, and MOLT-4), B-ALL (697 and KOPN-8), and BL cell lines (Raji) were incubated in the absence and presence of PRT in single and fractioned administration schemes. Metabolic activity was assessed by resazurin assay. Cell death was evaluated by optical microscopy (May-Grünwald-Giemsa staining) and by Flow Cytometry (FC; Annexin V/7-AAD staining). The expression of FAS, FAS-L, activated-caspase-3, phosphorylated NF-kB, mitochondrial membrane potential (Δ mit; JC-1) and oxidative stress [superoxide (O2-; DHE), hydrogen peroxide (H2O2, DCFH2DA), and reduced glutathione (GSH)] were also analyzed by FC. The results were statistically analyzed considering a level of significance of 95% (p<0.05).
Results: The results indicate that PRT reduced metabolic activity in a time-, dose- and cell line-dependent manner. KOPN-8, CEM, and RAJI (IC_{50} 50-75μM) were the most sensitive cells and MOLT-4 and JURKAT (IC_{50} 100μM) the less sensitive. Single and fractional administration regimens showed similar results. PRT induced cell death mainly by apoptosis associated with an increase in activated-caspases expression, decrease in Δ mit and an increase in oxidative stress levels (increased ROS and decreased GSH) in all cell lines. The morphological aspects observed in cells treated with PRT, such as blebbing and nuclear fragmentation, confirmed apoptosis induction. In addition, PRT also increased FAS and FAS-L expression levels in all KOPN8, 697 and MOLT4 cell lines. A cytostatic effect was observed in JURKAT (G_0/G_1 phase arrest) and MOLT-4 (G_2/M phase arrest) cells. Finally, PRT induced a decrease in phosphorylated p65 levels (a subunit of NF-KB) confirming the inhibition of NF-kB pathway.
Summary/Conclusion: In conclusion, these results suggest that PRT may represent a new potential therapeutic approach in ALL and BL. However, the therapeutic efficacy may depend on disease subtype.
This work was supported by CIMAGO and by the FCT through the fellowship SFRH/BD/51994/2012.

BOTANICAL ALKYL HYDROQUINONE HQ17(3) INDUCES ENDOPLASMIC RETICULUM STRESS, MITOCHONDRIAL CALCIUM OVERLOADED AND MITOPHAGY TO EXERTS CYTOTOXICITY TO PHILADELPHIA CHROMOSOME(+) SUP-B15 ALL CELLS

Y.-C. Jou[1], C.-W. Chen[1], Y.-Y. Kuo[2], L.-I. Lin[1], C.-Y. Hu[1,*]

[1]Department of Clinical Laboratory Sciences and Medical Biotechnology, [2]Graduate Institute of Oncology, College of Medicine, National Taiwan University, Taipei, Taiwan, Republic of China

Background: Acute lymphoblastic leukemias (ALLs) harboring t(9;22)(Ph^+-ALL) is classified as very high risk (VHR) ALL due to poor clinical outcome irrespective of intensive chemotherapies and tyrosine kinase inhibitor treatment. Development of new adjuvant therapeutics will provide great value. HQ17(3)[10'(Z),13'(E),15'(E)-heptadecatrienyl hydroquinone] isolated from sap of the lacquer tree showed potent cytotoxic effect in 24 hours at micromolar concentration on several ALL cell lines, including Imatinib-refractory Ph^+-ALL SUP-B15 cells, spared normal PB leukocytes, and non-toxic in experimental rats. HQ17(3) presents as a potential anti-leukemic agents and a model for designing anti-leukemic regimen. We previously showed HQ17(3)-induced cell demise was characterized by oxidative stress, mitochondrial membrane potential (MMP) loss and nuclear DNA fragmentation. HQ17(3)-induced cell death is caspase-independent, and is different from the RIP1-mediated necroptosis or lysosomal permeabilization-mediated cell death since inhibitors to caspases, RIP-1K or lysosomal cathepsins/proteases failed to protect SUP-B15 cells from death. HQ17(3) enhanced autophagic flow and autophagy inhibitors attenuated the cell death. Interestingly, the ER stress markers (chaperon Grp78 and phosphorylated-eIF2a) were found upregulated as early as 5hr after HQ17(3) treatment.

Aims: To illustrate the characters of the HQ17(3)-induced non-classical death on Ph+-SUP-B15 cells, focus on ER stress and mitochondrial Ca^{2+} homeostasis.
Methods: Cell growth inhibition in response to HQ17(3) or inhibitors was analyzed by ACP assay. Annexin V/PI and flow cytometry analysis detected cell death. Autophagy was revealed by aggregation of ectopically expressed EGFP-LC3. MFN1/2, OPA1 (mitochondrial markers) were analyzed by western blot. Nuclear accumulation of apoptosis inducing factor (AIF), colocalization of mitochondrial COX-IV and LC3-II (mitophagy) were revealed by immunofluorescence stain and confocal microscopy. Mitochondrial Ca^{2+} [Ca^{2+}_m] accumulation was shown by fluorescent Rhod-2 probe, mitochondrial superoxide was measured after Mitosox stain.
Results: We showed [Ca^{2+}_m] accumulation at the time ER stress occurred, accompanied by mitochondrial superoxide elevation, followed by MMP loss and nuclear translocation of apoptosis-inducing factor (AIF). However, inhibition of AIF cleavage by calpain inhibitor PD150606 reduced the HQ17(3)-induced cell death slightly. Further, Ca^{2+} chelator Bapta-AM prevented [Ca^{2+}_m] overload and rescued cell death more effectively, indicating [Ca^{2+}_m] participated in other aspects in cell death. HQ17(3) treatment lead to decreased mitochondrial proteins MFN1/2 and OPA1, while Mitotracker green stain showed significant loss of mitochondrial mass preceded cell death, indicating damaged mitochondria succumbed to mitophagy, which was confirmed by the presence of COX IV and LC3B co-localization.
Summary/Conclusion: In Ph+-ALL SUP-B15 cells HQ17(3) induces ER stress by yet-defined mechanism, mobilizes Ca^{2+} to mitochondria, results in cleavage and release of AIF to mediate chromatin fragmentation, Ca^{2+}-overload leads to oxidative stress in turn and perturbs mitochondria integrity. Damaged mitochondria induce extensive mitophagy and cell death ensues. Therefore, agents that help elicit similar intricate effector network associated with ER/mitochondria stress will have potential as adjuvants controlling the VHR-ALL cells refractory to conventional chemotherapies and TKI regime.

CELL CYCLE REGULATORY GENE (CDKN2A/2B) DELETIONS CORRELATE WITH POOR EVENT FREE SURVIVAL IN PEDIATRIC ALL

P. Bhatia[1,*], K.M.[2], M. Singh[3], A. Trehan[4], M. Sachdeva[5], D. Bansal[4], R. Jain[1]

[1]Asst Professor, Hematology Oncology Unit (Lab Hematology) Dept Of Pediatrics, [2]PGIMER, chandigarh, India, [3]Pediatric Hematology-oncology, [4]Professor Pediatric Hematology-oncology, [5]Additional Professor, Dept Of Hematology, PGIMER, chandigarh, India

Background: Studies have shown that approximately 30 to 35% of pediatric ALL cases are known to harbor genetic abnormalities in cell differentiation, cell cycle control and apoptosis related genes. These genetic abnormalities are prognostically important changes that can influence treatment outcome. Their early recognition is important to individualize treatment decisions and improve overall survival.
Aims: To note the frequency of cell cycle regulatory gene copy number abnormalities in pediatric Acute Lymphoblastic Leukemia (ALL) cases using MLPA assay and to correlate the copy number abnormality status with response to chemotherapy and outcome parameters.
Methods: 87 prospectively diagnosed and confirmed ALL cases were enrolled and cell cycle regulatory gene deletions (CDKN2A/2B and RB1) were noted by MLPA assay using ALL-P-335 kit and data analyzed by Coeffalyzer software. In addition clinical and outcome data was recorded as per treatment record files. Ethical clearance of study was obtained from Institute's Ethics Committee.
Results: Mean age in the study group was 5.87 years (6 months-12 years) with a M;F ratio of 2:1. There were 74 B-ALL and 13 T-ALL cases. The mean TLC in our study group was 1,08,499/cu mm and Good Prednisolone response at day 8 was noted in 70 (81.4%) cases. Day 35 post induction showed M1 response in 82(95.3%) children and M2+M3 response in a total of 4(4.7%) children, while data available in 73 B-ALL and 5 T-ALL cases showed MRD >0.01% in 21(28.7%) B-ALL and 1 T-ALL case respectively. 44.8% of children in the cohort had cell cycle regulatory gene copy number abnormalities of which frequency of CDKN2A/2B gene copy number abnormalities (both B and T cell ALL) was 43.6% and frequency of RB1 gene copy number abnormalities was 3.4% (p value-0.00). All the T cell ALL (100%) cases in the cohort had cell cycle regulatory gene copy number abnormalities, compared to 35.1% in B cell ALL cases (p value-0.00). In addition predominantly homozygous CDKN2A/2B gene deletions in T-ALL (92%) as compared to B-ALL (48%) were noted (p-0.00). On correlation of cell cycle regulatory gene deletional *versus* non deletional group with standard ALL risk factors and treatment outcome parameters, a significant correlation was noted of deletional group with high TLC (p -0.00), T-ALL phenotypes (p -0.00), events (p -0.28) and BCR-Abl gene positivity (p-0.00). The mean EFS duration was further decreased by 8.1 months in cases with only CDKN2A/2B gene deletions in comparison with those without cell cycle regulatory gene copy number abnormalities. (p value-0.00).
Summary/Conclusion: Our study results highlight that CDKN2A/2B deletions are common in B-ALL and seen in high frequency in T-ALL (100%) our study. Moreover CDKN2A/2B deletions in B-ALL confer a poor EFS in multivariate analysis suggesting their potential role as a poor prognostic marker in B-ALL.

PB1611

NOVEL COMBINATION OF RESVERATROL AND CERAMIDE METABOLIZING ENZYMES SYNERGISTICALLY ENHANCES THE ANTI-PROLIFERATIVE AND PRO-APOPTOTIC EFFECTS ON PH + ACUTE LYMPHOBLASTIC LEUKEMIA

A. Adan*, O. Oğuz

Molecular Biology and Genetics, Abdullah Gul University, Kayseri, Turkey

Background: Philadelphia chromosome positive acute lymphoblastic leukemia (Ph + ALL), expressing BCR/ABL oncoprotein, is the most common subtype with high mortality rate and poor prognosis. Overall survival rate can only be extented to a few years after treatment and complete remission can not be achieved. Therefore, it is quite important to investigate new therapeutic agents and define potential novel cellular targets for the treatment. The anticarcinogenic potential of resveratrol has not been *investigated in Ph +* ALL. Bioactive sphingolipids are a lipid family with important members including ceramide, sphingosine-1-phosphate (S1P) and glucosyl ceramide (GC), which have significant roles in the regulation of cell divison, growth, metastasis and apoptosis. Ceramide produced through *de novo* synthesis pathway (Serine Palmitoyl Transferase (SPT) is a key enzyme subjected to regulation) is a central molecule in sphingolipid metabolism playing significant roles in the induction of apoptosis. On the other hand, the conversion of ceramide into sphingosine-1-phosphate (S1P) by sphingosine kinase 1 (SK-1) or/and into glucosyl ceramide by glucosyl ceramide synthase (GCS) induces the proliferation of cancer cells. Therefore, ceramide metabolism and the regulation of enzymes such as SPT, SK-1 and GCS have a great therapeutic importance.
Aims: It is aimed to investigate *therapeutic potential of resveratrol on Ph + ALL cells and to identifiy potential mechanisms behind resveratol-mediated apoptosis in association with targeting of ceramide metabolism and regulation of BCR-ABL.*
Methods: The antiproliferative and apoptotic effects of resveratrol, SPT inhibitor (myriocin), SK-1 inhibitor (SKI II), GCS inhibitor (PDMP), resveratrol:myriocin, resveratrol:SKI-II and resveratrol: PDMP combinations on Ph + ALL cells, SD-1 and SUP-B15, are investigated by cell proliferation assay and flow cytometry (annexin-V/PI), respectively. Caspase-3 and PARP levels and cytochrome c release are checked by western blot to confirm apoptosis induction. The synergistic, antagonistic or additive effects of the mentioned combinations and the combination indexes are calculated using Calcusyn program. The cytostatic effects of each agent alone and combinations are determined by PI staining. BCR-ABL levels are determined by western blot after the cells are exposured to each agent alone and defined combinations.
Results: Proliferation of Ph + ALL cells were reduced dose and time dependently with treatment of either drug except myriocin. Drug interaction relationship were studied using Calcusyn software and effects of synergistic combinations (CI<1) involving lower doses of resveratrol and ceramide metabolism enzymes were selected for further studies.These combinations significantly induced apoptosis via enhanced PARP cleavage, caspase-3 activation and cytrochrome-c release. Combinations also caused ceell cycle arrest at different phases and modulated the expression of BCR-ABL.
Summary/Conclusion: The *anti-leukemic effect of resveratrol on Ph + ALL cells and mechanisms behind its action are enlightened by targeting critical enzymes involved in ceramide metabolism and regulating BCR-ABL for the first time.* Furthermore, resveratrol:SPT inhibitör, resveratrol:SK-1 inhibitor and resveratrol:GCS inhibitor combinations could be considered as a novel approach for the treatment of leukemia.

INHIBITION OF DNA-PK ENHANCES CHEMOSENSITIVITY OF B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA CELLS TO DOXORUBICIN

F. Alikarami[1], M. Faranoush[2], P. Hayat[3], A. Kazemi[1], M. Safa[1,*]

[1]Iran University of Medical Science, [2]Pediatric Growth and Development Research Center, Institute of Endocrinology and Metabolism, Iran University of Medical

Science, [3]Cellular and Molecular Research Center, Iran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: DNA damage repair pathways greatly affect the response to genotoxic drugs in cancer cells, so inhibition of such pathways could be a potentially useful strategy to enhance chemosensitivity. DNA-dependent protein kinase (DNA-PK) plays a crucial role in the repair of DNA double-strand breaks (DSBs) that are probably one of the most detrimental types of DNA damage. It has been shown that DNA-PK is highly expressed in B-cell precursor acute lymphoblastic leukemia (BCP-ALL) cells. Less well appreciated was the effect of DNA-PK inhibition on sensitivity of BCP-ALL cells to DNA-damaging agents.
Aims: Disruptions in DNA repair system is a way to induce cell death. So, we determine to evaluate the effect of DNA-PK inhibition on sensitivity of BCP-ALL cells to DNA-damaging agents. In the present study, we investigated the effects of DNA-PK inhibitor (NU7441) on doxorubicin-induced DSBs in BCP-ALL cells.
Methods: NALM-6 and SUP-B15 cells (BCP-ALL cell lines) were treated with doxorubicin in presence or absence of different concentration of DNA-PK inhibitor (NU7441). The apoptosis was assessed using Annexin V-PI staining followed by flow cytometry analysis. Phosphorylated H2AX was detected by immunofluorescence staining. The expression levels of a repertoire of apoptotic and anti-apoptotic proteins were assessed by western blot analysis. qRT-PCR were used to evaluate the gene expression levels.
Results: Here, we show that the DNA-PK inhibitor NU7441 increased doxorubicin-induced apoptosis in BCP-ALL cell lines, correlating with a reduction in DSB repair measured by γ-H2AX foci. NU7441 affected the cell cycle distribution and the cell cycle regulatory molecules in combination with doxorubicin treatment. Doxorubicin-induced DNA-PK phosphorylation was decreased in the presence of NU7441. Apoptosis induction by the combined treatment was associated with marked reduction of Bcl-2 and survivin and a significant increase of Bax mRNA expression levels.
Summary/Conclusion: our data indicate that inhibition of DNA-PK might be an effective approach to enhance the tumor-cell-killing effects of DNA-damaging agents such as doxorubicin in BCP-ALL and may deliver novel, targeted therapy into the clinic.

EPIGENETIC MODULATORS SHOW *IN VITRO* THERAPEUTIC POTENTIAL TO TREAT B CELL ACUTE LYMPHOBLASTIC LEUKEMIA

B. Ribau[1], J. Jorge[2,3], R. Alves[2,3], I.P. Ribeiro[3,4], I. Marques Carreira[3,4], A.C. Gonçalves[2,3], A.B. Sarmento Ribeiro[2,3,5,6,*]

[1]Chemistry Department, Aveiro University, Aveiro, [2]Laboratory of Oncobiology and Hematology and University Clinic of Hematology, Faculty of Medicine, University of Coimbra (FMUC), [3]Coimbra Institute for Clinical and Biomedical Research (iCBR)-Group of Environment Genetics and Oncobiology (CIMAGO), FMUC, [4]Laboratory of Cytogenetics and Genomics, Faculty of Medicine, University of Coimbra (FMUC), [5]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, [6]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: B cell acute lymphoblastic leukemia (B-ALL) is the most frequent hematologic neoplasia in children and is characterized by the accumulation of blast cells that are phenotypically reminiscent of normal stages of B-cell differentiation. Epigenetic alterations, namely DNA methylation and histone modifications, are involved in B-ALL development and progression. Unlike chromosomal translocations or gene mutations, which induce permanent changes in the DNA sequence, hypermethylation of gene promoters is a reversible event that could be targeted with therapeutic agents designed to alter aberrant epigenetic events.
Aims: The aim of this study was to evaluate the therapeutic potential of hypomethylating agents ([DNMTi: Azacitidine (5-AC) and Decitabine (DAC)]) and histone deacetylase inhibitors [HDACi: Panobinostat (PAN) and Vorinostat (SAHA)], in monotherapy and in combination therapy, in *in vitro* models of B-ALL.
Methods: Two B-ALL cell lines, the KOPN-8 and 697 cells, were incubated in the absence and presence of DNMTis and/or HDACis, in monotherapy and in therapeutic combination. Cell viability was determined by the FMCA assay (Fluorometric Microculture Cytotoxicity Assay). Cell death was evaluated by optical microscopy (May-Grünwald-Giemsa staining) and by Flow Cytometry (FC; Annexin V/7-AAD double staining). The hypomethylating effect was evaluated through 5-methylcytosine (5-mC) levels analyzed by FC and the methylation status of 24 tumor suppressor genes was carried out by MS-MLPA. The results were analyzed statistically considering a significance level of 95% ($p<0.05$).
Results: The results showed that 697 cells have more tumor suppressor genes methylated (15/24) than KOPN8 cells (12/24). The studied drugs reduced cell viability in a time-, dose- and cell line-dependent manner, being the 697 cells more sensitive than KOPN-8 cells. B-ALL cells were found to be more sensitive to DAC (IC_{50} 697=10μM; IC_{50} KOPN-8 >15μM) than to 5-AC (IC_{50} 697=15μM; IC_{50} KOPN-8 >20μM), after 72h of treatment. They were also more sensitive to PAN (IC_{50} 697=7.5nM; IC_{50} KOPN-8 >20nM) than to SAHA (IC_{50} 697=750nM; IC_{50} KOPN-8=1000nM). In addition, therapeutic associations of DAC with PAN or SAHA reduced more effectively the cell viability when compared to monotherapy treatments. These drugs induced predominantly apoptosis in 697 cells and apoptosis and necrosis in KOPN-8 cells. Cell death by apoptosis was confirmed by morphological aspects such as blebbing, cellular contraction, and nuclear fragmentation. Moreover, SAHA induced cell cycle arrest in phase S and G_0/G_1, respectively in 697 and KOPN-8 cells. Finally, both DNMTi and their association with PAN induced a decrease in 5-mC levels and induced demethylation of at least two tumor suppressor genes (697: *TP73*, *KLLN*, *MGMT*, and *CD44*; KOPN8: *MGMT* and *STK11*).
Summary/Conclusion: Our results suggest the therapeutic potential of epigenetic modulators in the treatment of B-ALL in monotherapy and in the usefulness of the association of DNMTi with panobinostat. However, the therapeutic efficacy may depend on the methylation profile.
This work was supported by CIMAGO and by the FCT through the fellowship SFRH/BD/51994/2012.

Georgi", Plovdiv, [5]Laboratory of Hematopathology & Immunology, National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: The cryptic translocation t(12;21)(p13;q22) and the respective *ETV6-RUNX1* fusion gene, is the most common genetic abnormality in childhood acute lymphoblastic leukemia (ALL), accounting for 20%>25% of the cases, while it is a very rare finding in adolescents and adults with ALL, with an incidence of ≤1%. Additional chromosome abnormalities are detected in more than two thirds of cases, however the t(4;9)(q21;p24) has not been reported so far. This abnormality that results in the formation of *SEC31A-JAK2* fusion gene has been previously reported as the first recurrent *JAK2*-associated translocation in classical Hodgkin lymphoma. To the best of our knowledge only two other cases of t(4;9)(q21;p24) have been reported so far-in a patient with ALL, with unknown *ETV6-RUNX1* status and in a patient with undifferentiated lung carcinoma.
Aims: To present for the first time a rare case of t(4;9)(q21;p24) in an adolescent with a molecularly defined *ETV6-RUNX1*-positive B-ALL.
Methods: A 19-old male was admitted to the hospital because of pancytopenia and elevated serum lactate dehydrogenase levels, tested in relation to complaints of acute thoracic back pain.
Results: On admission, the physical exam was unremarkable. The initial laboratory tests revealed white blood cell counts of $1.6x10^9$/l with no blasts; a hemoglobin level of 90 g/l and platelet counts of $10x10^9$/l. On aspirate smear, the bone marrow was markedly hypercellular with a subtotal infiltration with lymphoblasts. Flow cytometry of bone marrow detected a blast cells population accounting for 48.3% of all cells with the following phenotype: Syto41+/CD45dim+/CD19+/CD10+/ CD20-/CD34+/CD38+/ CD58+. Conventional cytogenetic analysis demonstrated an abnormal karyotype: 45,XY,-4, der(9)t(4;9)(q21;p24),14ps+[5]/46,XY,14ps+[15], while molecular analysis using qualitative reverse transcription polymerase chain reaction with two different sets of primers revealed the presence of *ETV6-RUNX1* (short type) transcripts. Based on these data a diagnosis of *ETV6-RUNX1*-positive B-cell precursor ALL was made and treatment was initiated according to the ALL-IC BFM 2009 protocol. At day 33 a complete hematological remission was registered with a minimal residual disease of 0,003% detected by flow cytometry. ETV6-RUNX1 transcripts gradually decreases up to undetectable levels. Currently, our patients is still in complete hematological and molecular remission 2 years after treatment discontinuation.

Summary/Conclusion: In this study we report on a t(4;9)(q21;p24) in a male adolescent patient with B-ALL, also positive for the short type of *ETV6-RUNX1* transcipts. The presence of this rare additional abnormality, that is recurrent for another hematological malignancy, was not associated with specific clinical, morphological or immunophenotypic features and it did not affect the characteristic favorable prognosis associated with *ETV6-RUNX1.*

HIGH EXPRESSION OF PARTITION-DEFECTIVE 3 (PARD-3) IS ASSOCIATED WITH ADULT B CELL ACUTE LYMPHOBLASTIC LEUKEMIA

X. Yan*, J. Zhang, J.-M. Zhang, L.-X. Wu, X.-J. Huang, K.-Y. Liu, G.-R. Ruan

Institute of Hematology, Peking University People's hospital, Beijing, China

Background: The partition-defective 3 (PARD-3) gene is essential for the disassembly of the tight/ adhesive junctions and epithelial-mesenchymal transition (EMT) which is critical for tumor spreading. Previous research has shown that PARD-3 protein expression is frequently lost in primary esophageal squamous cell carcinoma(ESCC). In the progression of non-small-cell lung cancer (NSCLC), PARD-3 has also been verified to contribute to EMT, invasion, and chemoresistance in NSCLC. The effect of PARD-3 expression on adult B-cell acute lymphoblastic leukemia (ALL) has not been identified.
Aims: The purpose of this study was to investigate the transcriptional level of PARD-3 in adult B cell acute lymphoblastic leukemia.
Methods: A real-time quantitative reverse transcription-polymerase chain reaction assay based on Taq-Man fluorescence methodology was used to quantify the PARD-3 mRNA copy number in the bone marrow cells from patients with adult leukemia. Normal marrow samples from the allogeneic stem cell transplantation donors were served as control. Informed consent was obtained for every marrow sample.

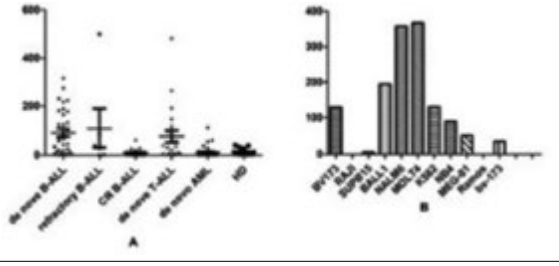

Figure 1.

Results: Expression levels of the PARD-3 in leukemia patients and normal donor marrow are shown in Figure 1. These results showed that the relative levels of PARD-3 gene expression in marrow from 32 newly diagnosed B-cell ALL (median 92.84%; range 0.002% 316.201%) was significantly higher than those of marrow from the 20 healthy donors (median 13.74%; range 2.93% 41.15%; *P*=0.004). Significant PARD-3 mRNA over expression was found in the *de novo* B-cell ALL patients compared with 32 treated B-cell ALL patients (median 10.46%; range 0.415% 64.489%) who achieved complete remission or 32 *de novo* AML (median 11.638%; range 0.021% 114.169%; *P*<0.0001). The expression levels of PARD-3 was higher in 6 refractory/relapsed B-cell ALL patients (median 110.315%; range 1.276% 499.772%) than that of newly diagnosed B-cell ALL, but no statistical significant difference was observed (*P*=0.72). Besides, no statistical significant difference was observed in 32 newly diagnosed AML (median 11.638%, range 0.021% 114.169%) and 20 healthy donors (*P*=0.72), but it was higher in BALL-1 and NALM6 cells from B cell ALL cell lines than in other cells from AML cell lines (Figure 1).
Summary/Conclusion: These observations suggest that PARD-3 is overexpressed in B-cell acute lymphoblastic leukemia and may play a role in the pathogenesis of B-cell acute lymphoblastic leukemia.

PB1616

NOTCH1 KNOCKDOWN PROMOTES THE GROWTH OF AND UPREGULATES NOTCH2 EXPRESSION IN JURKAT T-ALL CELLS

Y. Okuhashi[1,2,*], S. Tohda[2]

[1]Department of Medical technology, Tokyo University of Technology, [2]Department of Laboratory of Medicine, Tokyo Medical and Dental University, Tokyo, Japan

Background: NOTCH signaling is crucial for the growth of T-lymphoblastic leukemia (T-ALL) cells. We have previously reported that treatment with γ-secretase inhibitors (GSIs), which block NOTCH activation, suppresses the growth of several T-ALL cell lines. However, while GSI-XXI inhibited the proliferation of KOPT-K1 cellspromoted that of Jurkat cells, although both of these T-ALL cell lines harbor *NOTCH1*-activating mutations.
Aims: To elucidate the mechanism underlying the promotion of Jurkat cell growth by NOTCH inhibition.
Methods: KOPT-K1 and Jurkat cells were transfected with small interfering RNA (siRNA) targeting *NOTCH1* (siN1) or *NOTCH2* (siN2), or control siRNA (siCont) using the pipette tip chamber-based electroporation system. The effects of *NOTCH* knockdown on mRNA and protein expression were examined by quantitative RT-PCR and immunoblotting, respectively. Cell growth was assessed in three-day cultures by a colorimetric WST-8 assay, and the relative cell number was determined based on optical density measured using an ELISA plate reader and expressed as the percentage of the mean absorbance value normalized to that of siCont-transfected cells.
Results: Transfection with siN1 and siN2 selectively inhibited the expression of NOTCH1 and NOTCH2 (mRNA and protein), respectively, both in KOPT-K1 and Jurkat cells. *NOTCH1* and *NOTCH2* knockdown suppressed the growth of KOPT-K1 cells to 60% and 67%, respectively, but promoted that of Jurkat cells to 158% and 152%, respectively, of control. In Jurkat cells, *NOTCH1* knockdown abolished the expression of cleaved NOTCH1 fragment (active form of NOTCH1), downregulated HES1 and MYC, but slightly increased NOTCH2 levels, whereas *NOTCH2* knockdown slightly upregulated the levels of cleaved NOTCH1 fragment, HES1, MYC, and NOTCH1. In KOPT-K1 cells, *NOTCH1* knockdown decreased the expression of cleaved NOTCH1 fragment and HES1, while slightly increasing that of NOTCH2, whereas *NOTCH2* knockdown did not affect the expression of other proteins. The knockdown of *NOTCH1* and *2* did not affect the level of mTOR, Hedgehog, and Wnt signaling-related proteins in both cell lines.

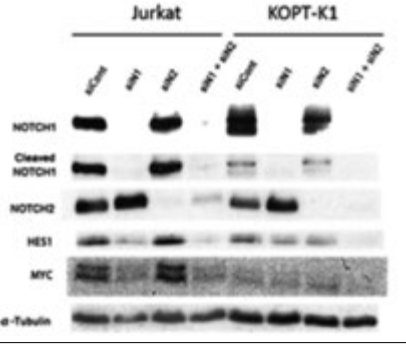

Figure 1.

Summary/Conclusion: In this study, we confirmed our previous findings that GSI-XXI treatment suppressed the growth of KOPT-K1 cells while promoting that of Jurkat cells using *NOTCH1*- and *NOTCH2*-specific siRNA. It is well known that NOTCH activation is oncogenic and promotes the growth of T-ALL cells. However, in Jurkat cells NOTCH obviously exerted the opposite effect. Interestingly, the knockdown of NOTCH2, similar to that of NOTCH1, affected the growth of the two cell lines, although they do not have *NOTCH2*-activating mutations. Furthermore, in Jurkat cells, we observed an interesting phenomenon that NOTCH1 knockdown upregulated NOTCH2 and vice versa, which might be related to the cell proliferation due to NOTCH suppression although this mechanism can not fully answer the question in the aim of this study. The underlying molecular mechanisms and the biological significance of the effect need to be further elucidated. Our results contribute to understanding of the role of NOTCH signaling in T-ALL cells and should promote the development of novel NOTCH-targeting therapies against T-ALL.

C-MYC INHIBITION BY SMALL MOLECULE INHIBITOR 10058-F4 CAUSES APOPTOTIC CELL DEATH AND ENHANCESVINCRISTINE INDUCED CYTOTOXICITY IN PRE-B-ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

N. Sheikh-Zeineddini*, N. Riyahi, M. Sayyadi, D. Bashash

Department of Hematology and Blood Banking, School of Allied Medical Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: In spite of impressive advances in therapeutic approaches, some of the patients with acute lymphoblastic leukemia (ALL) experience a bone marrow relapse with the approximate morbidity and mortality rate of 60%. Since aberrant expression of c-Myc contributes to the unlimited proliferative potential of malignant lymphoblasts, and may confer resistance to chemotherapeutic drugs, inhibition of c-Myc proto-oncogene is proving to be a daunting task for clinicians.
Aims: To assess the anti-tumor effect of c-Myc inhibition in ALL, Nalm-6 cells were treated with the different concentrations of small molecule inhibitor of c-Myc, 10058-F4.
Methods: MTT, Trypan blue, annexin/PI staining, cell cycle analysis, caspase-3 activity, and BrdU cell proliferation assay coupled with analysis of gene expression by using quantitative real-time PCR were applied to examine the effects and molecular mechanisms of action of 10058-F4.
Results: Our results indicated that c-Myc inhibition using 10058-F4 resulted in a considerable growth suppressive effect in Nalm-6 cells mostly through p73-mediated G1 arrest. Moreover, we found that the cytotoxic effects induced in inhibitor-treated cells were likely due to the induction of a caspase 3-mediated apoptosis, as revealed by the increased percentage of Annexin-V and Annexin-V/PI double positive cells in the drug-treated group. Noteworthy, the resulting data showed that combination of 10058-F4 and vincristine produced synergistic anticancer effects and provided an enhanced therapeutic efficacy in pre-B ALL-derived Nalm-6 cells.
Summary/Conclusion: Our study not only indicated the potential application of single agent of 10058-F4 in Nalm-6 cells but also outlined the therapeutic efficacy of the inhibitor in combination with the common chemotherapeutic drugs in pre-B ALL.

PB1618

FOXP3 KNOCKDOWN INHIBITS THE PROLIFERATION AND REDUCES NOTCH1 EXPRESSION OF T- LYMPHOBLASTIC LEUKEMIA CELLS

S. Yonekura*, M. Itoh, E. Shiratori, M. Ohtaka, S. Tohda

Laboratory medicine, Tokyo Medical and Dental University, Tokyo, Japan

Background: Forkhead box P3 (FOXP3) is a master transcriptional factor of regulatory T-cells (Tregs). Recent studies have shown that FOXP3 expression is associated with growth inhibition of various solid tumor cells such as gastric cancer and ovarian cancer. However, the role of FOXP3 in T-cell acute lymphoblastic leukemia (T-ALL) cells is not known. It was also reported that NOTCH signaling promoted the expression of FOXP3 in Tregs. However, little is known about the effects of FOXP3 expression on NOTCH expression in T-ALL cells.
Aims: To elucidate the effect of *FOXP3* knockdown on the proliferation and NOTCH expression of T-ALL cells.
Methods: The two T-ALL cell lines Jurkat and KOPT-K1, harboring an activating *NOTCH1* mutation, were transfected with small interfering RNA (siRNA) against *FOXP3* or control siRNA using an electroporation system. Cell growth was assessed in five-day cultures with a colorimetric assay. The relative cell number was determined based on optical density measured using an ELISA plate reader and expressed as the percentage of the mean absorbance value normalized to that of control cells. Cell morphology was examined in cytospin preparations from the cells cultured for 6 hours. They were stained with Wright's stain and observed under a microscope. The effects of *FOXP3* knockdown on mRNA expression were examined by quantitative RT-PCR.

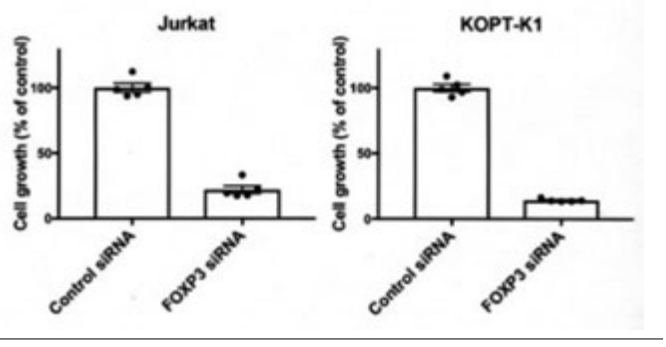

Figure 1.

Results: Transfection with *FOXP3* siRNA significantly reduced the *FOXP3* expression to 29% and 45% in Jurkat and KOPT-K1 cells, respectively. By *FOXP3* knockdown, cell growth was significantly suppressed to 22% and 14% in Jurkat and KOPT-K1 cells, respectively. Observation of cytospin preparations indicated that apoptotic cells with nuclear condensation and apoptotic bodies appeared in both cells. The expression of *NOTCH1* was significantly reduced to 56% and 60% compared with that of control in Jurkat and KOPT-K1 cells, respectively. *HES1* expression was significantly reduced to 52% and 34% in Jurkat and KOPT-K1 cells, respectively.
Summary/Conclusion: *FOXP3* knockdown suppressed the growth and induced apoptosis of the two T-ALL cell lines. This suggests that FOXP3 supports the growth of T-ALL cells although this can not be generalized in T-ALL because we just examined only two cell lines. We think that the role of FOXP3 on cell growth can diverge in different types of cancer. *FOXP3* knockdown downregulated *NOTCH1* expression in T-ALL cells. The observed growth suppression can be partly related to the downregulation of NOTCH1 signaling because NOTCH1 plays a role in the growth of some T-ALL cells. The underlying molecular mechanisms and the biological significance of the effect need to be further elucidated. Then, FOXP3 may be a potential therapeutic target in T-ALL.

PB1619

CENTAUREA ALBONITENS EXTRACT ENHANCES THE THERAPEUTIC EFFECTS OF VINCRISTINE IN LEUKEMIA CELLS BY INDUCING APOPTOSIS

F. Bahmani[1,*], A. Gharehbaghian[2], S. Esmaeili[3], D. Bashash[2,] N. Dehghan-Nayeri[2]

[1]Hematology and blood banking, Abadan school of medical science, Abadan, [2]hematology and blood banking, [3]Traditional Medicine and Materia Medica Research Center, shahid beheshti university of medical science, Tehran, Iran, Islamic Republic Of

Background: Drug-induced toxicities and dose-related side effects are the major challenges in the conventional cancer therapy by the chemo drugs. On the other hand, herbal derivatives have obtained a great research interest in the field of therapeutic applications because of their more favorable specifications including less toxicity, cost-effective and more physiologically compatible than the chemical drugs. *Centaurea* genus is one of the current medicinal plants, which has used in traditional medicine, However, there are rare studies to examine its anticancer properties against hematologic malignant cells.
Aims: For this purpose, we evaluated methanolic extract prepared from *Centaurea albonitens* Turrill extract (CAE) alone and in combination with Vincristine (VCR) for its potential cytotoxic effects in NALM-6, REH, NB4 and KMM-1 cell lines using the various approaches.
Methods: In this experimental study, to explore the effects of CAE and CAE/VCR on hematologic malignant cell lines, the cells were treated with increasing concentrations of extract and drug. Their cytotoxic and anti-proliferative effects were evaluated using trypan blue, MTT assay and DAPI staining. moreover, we performed annexin V/PI staining, cell cycle analysis, Caspase-3 activity assay and real-time RT-PCR to examine the mRNA expression level of BAX, BCL-2, p21 and c-MYC to further investigate how CAE and CAE/VCR exert their cytotoxic properties.
Results: In this study, we demonstrated *Centaurea albonitens* extract (CAE) induces cytotoxicity through G0/G1 phase arrest followed by apoptosis in a dose- and time- dependent manner, although with varying efficiency. Interestingly, MDBK normal cells didn't exhibit significant cytotoxicity after CAE treatment. Moreover, we found that low dose of CAE enhances anticancer effects of VCR in pre-B ALL cell lines (NALM-6 and REH). Further investigations validated synergistic anticancer activities of VCR and CAE through inducing apoptosis without significant cell cycle arrest.
Summary/Conclusion: Taken together, our results demonstrated for the first time that the methanolic extract of *Centaurea albonitens* can be considered as a potential anticancer agent and/or an enhancer of chemotherapeutic sensitivity of VCR.

PB1620

MINIMAL RESIDUAL DISEASE ANALYSIS BY FLOW CYTOMETRY IN CHILDHOOD ACUTE LYMPHOBLASTIC LEUKEMIA

I. Frikha[1,*], Y. Fakhfakh[1], N. Louati[2], S. Hdiji[1], H. Mnif[2], M. Medhaffer[1], M. Elloumi[1]

[1]Hematology, Hedi Chaker Hospital, Sfax, Tunisia, [2]Regional transfusion center, Habib Bourguiba Hospital, Sfax, Tunisia, Sfax, Tunisia

Background: The prognosis of acute lymphoblastic leukemia (ALL) in children

is greatly improved by identification of prognostic factors and better stratification in risk group. Through this study we specify the interest of the minimal residual disease (MRD) by flow cytometry in patients treated for ALL.
Aims: In our study, we evaluated the response of treatment in acute lymphoblastic leukemia of child by analyzed of minimal residual disease with flow cytometry.
Methods: In our study we are interested at the results of MRD performed by flow cytometry (CMF) on two points: Day 36 (TP1) and Day 63 (TP2), in children treated for ALL according to the protocol EORTC 58951 from January 2015 to June 2017. MRD is considered positive when TP1>10^{-2} and TP2>10^{-3}. Then we observed the impact of the MRD on relapse.
Results: We collected 45 cases of ALL who received an MDR response assessment. These are 33 boys and 12 girls (sex ratio=2.75). The median age at diagnosis was 8 years (2- 29 years). There are 32 cases of B phenotype and 13 cases of T phenotype. The median rate of WBC was 11G / L. Two patients are classified LR, 18 AR1, 13 AR2 and 12 HR. 44 patients (98%) achieved a complete remission after induction and one patient was in therapeutic failure. TP1 was done for 40 patients (89%), TP2 achievement rate was 78% and 67% of patients have the 2 points (TP1 and TP2). For the patients who had TP1: 2 were positive and relapsed, 27 patients were negative of which 9 (24%) relapsed (p=0.061). Of the 35 patients who had TP2, 9 were positive, of which 3 (33%) relapsed and 26 had TP2 negative, 7 of them (27%) relapsed (p=0.033). Of the 38 TP1 negative patients, 28 had a second point among them 6 patients had TP2 positive, of which 4 patients (67%) relapsed.
Summary/Conclusion: The MRD study is currently an element determinant in the prognosis of ALL. In our series, this study was conducted by CMF for lack of molecular biology. It shows an interest in the occurrence of relapse as well as in the literature. We plan to expand this study and make it protocol for all our patients and especially the involved in the therapeutic attitude.

PB1621

ADDITIONAL CYTOGENETIC ABNORMALITIES IN ADULT PATIENTS WITH PHILADELPHIA CHROMOSOME POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

O. Zotova[1,*], A. Lukianova[1], M. Valchuk[1], I. Vanko[1], Z. Maslyak[1], Y. Karol[2], Z. Misharina[3], V. Loginsky[1]

[1]SI «Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine», [2]5th Clinical City Hospital, Lviv, [3]SI «National Centre for Radiation Medicine, NAMS of Ukraine», Kyiv, Ukraine

Background: Philadelphia chromosome (Ph), the result of a reciprocal translocation involving chromosomes 9 and 22: t(9;22)(q34;q11), is the most frequent genetic aberration in adult acute lymphoblastic leukemia (ALL) and is found in 15-30% patients. Additional chromosomal abnormalities are often found (~50%) in association with t(9;22)(q34;q11). The most common are: additional copy of Ph-chromosome (extra Ph), deletions del(22q) and del(7q), monosomy 7, trisomy 8 and others. Conventional chemotherapy programs that have been effective in other ALL cases have been unable to induce response in adults with Ph-positive ALL. Use of imatinib mesylate and other tyrosine kinase inhibitors as part of treatment have greatly improved the rates of complete hematologic and molecular remission in these patients. Imatinib interim therapy might improve the curative potential of allogeneic stem cell transplantation.
Aims: Aim of this study was to detect additional chromosomal abnormalities in adult patients with Philadelphia chromosome positive ALL and determine frequency of them.
Methods: Cytogenetic investigations of bone marrow and/or peripheral blood cells from 50 newly diagnosed adult patients with ALL were performed. The methods of conventional cytogenetics (GTG) and fluorescence *in situ* hybridization (FISH) were used.
Results: Cytogenetic investigations were performed in 50 newly diagnosed patients with ALL. Chromosomal aberrations of various kinds were found in 32 (64%) cases. According to the karyotype analysis patients were classified by risk groups: the group of patients with unfavorable cytogenetic markers (hypodiploidy, t(4;11)(q21;q23), t(9;22)(q34;q11), multiple changes (≥3)), the intermediate risk group without significant prognostic markers and the group with favorable prognostic factors (t(12;21)(p13;q22), high hyperdiploidy). Ph-chromosome was found in 8 (16%) cases. Five patients (62,5%), except for abnormal ones, had one or more normal metaphases in their karyotype. Of 8 patients with Ph-positive ALL, 3 (37,5%) had only Ph-chromosome, whereas other 5 (62,5%)-had additional cytogenetic abnormalities. Spectrum of additional chromosomal aberrations was as follows: extra Ph-chromosome and trisomy 8 (2 cases), extra Ph-chromosome and del(7)(q31) (1 case), trisomy 21 (1 case), high hyperdiploidy (57 chromosomes, extra Ph, trisomies X, 2, 4, 6, 8, 11, 14, 17, tetrasomy 21) (1 case). Cytogenetic investigations at relapse were performed in one case. Secondary chromosomal abnormalities in association with t(9;22)(q34;q11), both structural and numerical, were detected in this case, namely 1-2 additional copies of Ph, deletion del(1)(q24), trisomies 3, 6, 8 and marker chromosome. Presence of the additional/secondary chromosomal aberrations is the sign of clonal evolution and progression of disease and appears to have a significant deleterious effect on outcomes post allogeneic stem cell transplantation.
Summary/Conclusion: In our study frequency of Philadelphia chromosome in patients with ALL was 16%, which is comparable to the data reported in the literature. The most common additional chromosomal abnormalities in association with t(9;22)(q34;q11) were: extra Ph (80%) and trisomy 8 (60%). Presence of the additional/secondary chromosomal aberrations in Ph-positive cells is the sign of clonal evolution and disease progression.

PB1622

METHANOLIC EXTRACT FROM AERIAL PARTS OF ARTEMISIA ANNUA L. INDUCES CYTOTOXICITY AND ENHANCESVINCRISTINE INDUCED ANTICANCER EFFECT IN PRE-B ACUTE LYMPHOBLASTIC LEUKEMIA CELLS

P. Mashati*, S. Esmaeili, N. Dehghan-Nayeri, D. Bashash, M. Darvishi, A. Gharehbaghian

Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: Since the time immemorial, medicinal herbs have been broadly used as primary source for treatment of cancer, either applied individually or as adjuvant with conventional treatments. Nowadays, a remarkable attention has been drawn towards the effective therapeutic characteristic of natural products targeting cancerous cells.
Aims: This study aimed to investigate the anti-cancer effect of Artemisia annua extract (AAE), a medicinal Chinese herb alone and in combination with a microtubule binding agent used in ALL treatment, vincristine (VCR), in B-Acute lymphoblastic leukemia (ALL) Nalm-6 and Reh cells.
Methods: Cytotoxic activity of AAE and VCR was determined using MTT assay in Nalm-6 and Reh cell lines and synergism was evaluated using the CompuSyn software. Caspase 3 activity and Annexin/PI staining was performed for apoptosis assessment. The expression level of apoptosis-related genes, caspase 3, Bax and Bcl-2 were determined using real time-PCR. One-way ANOVA and post hoc Tukey multiple comparisons were used for statistical analysis.
Results: We found that treatment of the leukemic cells with increasing concentrations of this extract reduced (30 and 40 µg/ml) the viability and growth of the cells through caspase 3-dependent apoptosis after 48 h. Interestingly, the growth inhibitory activity of the extract after 48 h was more potentiated when combined with 0.1 and 1 nM (VCR), compared with either agent alone. Moreover, real-time PCR analysis showed that VCR-induced apoptosis was augmented by AAE through alteration of Bax and Bcl-2 mRNA expression, as the most substantial indicators of apoptosis.
Summary/Conclusion: Overall, owing to nontoxic nature of AAE and its explicit role in enhancing VCR effectiveness, our study provides a new insight into the development of novel combinatorial approach in ALL using natural herbs; however, more investigation, including clinical trial, is warranted to indicate the effectiveness of this extract in the treatment of acute lymphoblastic leukemia.

PB1623

THE ROLE OF PTEN AND ITS PSEUDOGENE PTENP1 IN THE PROLIFERATION OF PTEN-NULL JURKAT T-ALL CELLS

Y. Okuhashi[1,2,*], S. Tohda[2]

[1]Department of Medical technology, Tokyo University of Technology, [2]Department of Laboratory Medicine, Tokyo Medical and Dental University, Tokyo, Japan

Background: NOTCH/HES and AKT/mTOR pathways play important roles in the growth of T-lymphoblastic leukemia (T-ALL) cells. We have previously reported that treatment with γ-secretase inhibitor (GSI)-XXI, which prevents NOTCH activation, suppressed the growth of some T-ALL cell lines such as KOPT-K1, but promoted that of Jurkat cells, although both cell lines harbor activating *NOTCH1* mutations. Given that Jurkat cells are *PTEN*-null, whereas KOPT-K1 cells are *PTEN*-wild type and that a NOTCH target HES1 downregulates PTEN expression, we hypothesized that the interplay among PTEN/AKT, NOTCH and its related pathways may regulate the growth of Jurkat cells.

Aims: To elucidate the mechanism underlying the induction of Jurkat cell growth by GSI, we examined the role of *PTEN* and its pseudogene *PTENP1* reported to act as a tumor suppressor in some cancers.
Methods: Cells were transfected with small interfering RNAs targeting *PTEN* (siPTEN) and *PTENP1* (siPTENP1), or control siRNA (siCont) by electroporation and analyzed for mRNA and protein expression by quantitative RT-PCR and immunoblotting, respectively. Cell growth was examined by a colorimetric WST-8 assay in three-day cultures; optical density (OD) was measured using an ELISA plate reader and cell growth was calculated as the percentage of the OD value normalized to that of siCont-transfected cells. To inhibit NOTCH activation, cells were treated with GSI-XXI.
Results: PTEN mRNA and protein were detected in KOPT-K1 cells but not in Jurkat cells. In KOPT-K1 cells, transfection with siPTEN inhibited *PTEN* mRNA and protein expression but did not affect cell growth; however, the proliferation of siPTEN-treated cells was slightly promoted by GSI treatment. In Jurkat cells, both siPTEN and siPTENP1 suppressed cell growth to 74% and 69% of control, respectively. Furthermore, transfection with siPTEN increased the expression of NOTCH, mTOR, WNT, and HEDGEHOG signaling proteins such as NOTCH1, cleaved NOTCH1, NOTCH2, MYC, AKT, p-AKT, p-mTOR, S6K, p-S6K, CTNNB1, p-CTNNB1, and GLI1 in Jurkat cells, but not in KOPT-K1 cells as shown in Figure 1.

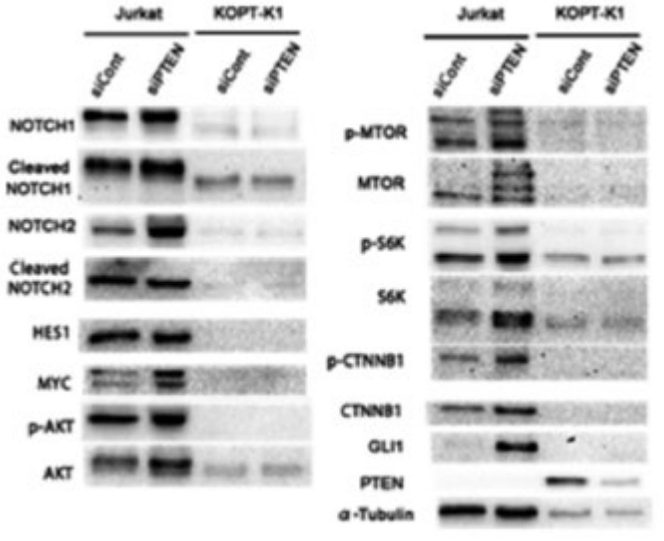

Figure 1.

Summary/Conclusion: Our study resulted in three interesting findings. First, siPTEN transfection suppressed the growth of PTEN-null Jurkat cells. One possible explanation is that siPTEN might bind to *PTENP1* mRNA which has high sequence homology to *PTEN* mRNA; this notion is supported by the fact that transfection with siPTENP1 also suppressed Jurkat cell proliferation. Second, the inhibition of Jurkat cell growth by siPTEN was accompanied by the upregulation of cell proliferation-inducing proteins in NOTCH, mTOR, WNT, and HEDGEHOG pathways. This seeming discrepancy may be related to our previous finding that GSI treatment promoted the growth of Jurkat cells, *i.e.*, that NOTCH activation apparently has suppressive effects on Jurkat cell proliferation. It is reported that *PTEN* expression is modulated by binding of some microRNAs and that *PTENP1* transcript acts as a decoy for microRNA binding; therefore, siPTEN might downregulate *PTENP1*, which might affect the level of these growth-related microRNAs and cell growth. Third, GSI treatment promoted the proliferation of *PTEN*-knockdown KOPT-K1 cells similar to that of *PTEN*-null Jurkat cells, suggesting that cell growth stimulation by GSI may be associated with PTEN deficiency. Although our findings are not consistent with well-known mechanisms of NOTCH signaling, elucidation of these phenomena should further development of effective NOTCH-targeting therapies against T-ALL.

PB1624

THE DETECTION OF P2RY8-CRLF2 FUSION IN ACUTE LYMPHOBLASTIC LEUKEMIA

D. Sae-Chua*, T. Siriboonpiputtana, N. Limsuwanachot, B. Rerkamnuaychoke, S. Pakakasama

Pathology, Ramathibodi Hospital, Bangkok, Thailand

Background: Acute lymphoblastic leukemia (ALL) is recognised as the most common cancers in childhood and a major cause of sickness and death in adults. Recently, *CRLF2* rearrangements were frequently identified in Ph-like acute lymphoblastic leukemia with the aggressive disease phenotype.
Aims: In this report, we performed a conventional RT-PCR method to detect *P2RY8-CRLF2* fusion which known as the most common *CRLF2* rearrangements in Ph-like ALL in childhood.
Methods: Conventional RT-PCR was performed to analyse *P2RY8-CRLF2* fusion in RNA isolated from bone marrow samples of 87 newly diagnosed childhood ALL patients. The *P2RY8-CRLF2* fusion sequence was subsequently confirmed by using Sanger sequencing technique.
Results: We found that 2 out of 87 patients (2.3%) are positive for *P2RY8-CRLF2* fusion. Additionally, one patient with *P2RY8-CRLF2* fusion was affected with Down syndrome (trisomy 21). Sequencing analysis on *P2RY8-CRLF2* fusion sequences in both two positive samples revealed that the fusion breakpoint is located at 111 nucleotides upper the start codon of *P2RY8* sequence (XM_011545631.2) and 2 nucleotides before the start codon of *CRLF2* sequence (NM_022148.3).
Summary/Conclusion: We could detect a *P2RY8-CRLF2* fusion by using a simple RT-PCR technique. Furthermore, *P2RY8-CRLF2* fusion sequence was conserved in our tested samples. In recent future, we are going to deeply investigate the function of *P2RY8-CRLF2* fusion in the initiation of Ph-like ALL in both *in vitro* and in mouse model.

PB1625

NOTCH PATHWAY AS A THERAPEUTIC TARGET IN ACUTE LYMPHOBLASTIC LEUKEMIA

J. Jorge[1,2], A. Pires[2], R.S. Alves[1,2], A.C. Gonçalves[1,2], A.B. Sarmento-Ribeiro[1,2,3,4,*]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR)-Group of Environment Genetics and Oncobiology (CIMAGO), [2]Laboratory of Oncobiology and Hematology, Faculty of Medicine, University of Coimbra (FMUC), [3]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, [4]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), Coimbra, Portugal

Background: Acute Lymphoblastic Leukaemia (ALL) is a malignant disease of hematopoietic system in which early lymphoid precursors proliferate and replace the normal hematopoietic cells, affecting both linages, B and T cells (B-ALL and T-ALL). NOTCH pathway is an evolutionary conserved signalling pathway that plays a significant role in cell fate decision during development, stem cell self-renewal and differentiation in haematopoiesis. Deregulation of NOTCH signalling was already reported in haematological disorders and various solid tumours, namely in T-ALL, were activating *NOTCH1* mutations are present in more than half patients, playing a significant role in its pathogenesis. Therefore, modulation of NOTCH signalling pathway, for example with gamma-secretase inhibitors, might provide a potential novel therapeutic approach in ALL.
Aims: In this context, the aim of this study was to evaluate the NOTCH pathway as a therapeutic target in ALL, using a -secretase inhibitor in two *in vitro* models of ALL.
Methods: For this purpose, we used two different ALL cell lines, CEM a T-ALL and KOPN-8 a B-ALL cell line. These cells were incubated in the absence and presence of increasing concentrations of the -secretase inhibitor, GSI-XXI (20μM-50μM). Cell viability and proliferation were assessed by trypan blue exclusion assay. Cell death was evaluated by optical microscopy and flow cytometry (FC) using annexin V/propidium iodide double staining and JC-1 probe to assess mitochondrial membrane potential. Apoptotic protein levels (BAX and BCL-2) and cell cycle distribution were also evaluated by FC. The expression levels of *CCND1*, *CCNB1*, *CCNE1* and *NF- B* genes were determined by RT-PCR. Results were considered statistically significant when $p<0,05$.
Results: Our results suggest that GSI-XXI reduced cell proliferation and viability in a dose- and cell type dependent manner with an IC_{50} at 24h of approximately 40μM for CEM and 30μM for KOPN-8 cells. This compound induced cell death mainly by apoptosis in both cell lines confirmed by morphological analysis, mediated by an increase in BAX/BCL-2 ratio and a decrease in mitochondrial membrane potential. The analysis of cell cycle also revealed a significant arrest in G0/G1 phase in CEM cells. This analysis also showed a sub-G1 peak in KOPN-8 treated cells, which correspond to DNA fragmentation a typical feature of apoptosis. Finally, GSI-XXI did not induce significant changes in the expression levels of *CCND1*, *CCNB1*, *CCNE1* and *NF- B* genes.
Summary/Conclusion: In conclusion, if these results can be translated to clinical practice, they suggest that NOTCH pathway and -secretase inhibitors, like GSI-XXI, might be a good therapeutic approach in acute lymphoblastic leukaemia patients.

Acute lymphoblastic leukemia – Clinical

EXPERIENCE OF TREATMENT OF ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN OF WESTERN UKRAINIAN SPECIALIZED CHILDREN'S MEDICAL CENTRE, LVIV

O. Dorosh[1,*], I. Tsymbalyuk-Voloshyn[1], R. Polishchuk[1], O. Troyanovska[2], O. Vorobel[1], O. Kozlova[1], A. Stepanyuk[1], L. Skoropad[1], L. Dubey[3], K. Bodak[1]

[1]Department of Hematology and Intensive Chemotherapy, Lviv Regional Council Public Institution "Western Ukrainian Specialized Children's Medical Centre", [2]Assistant, Department of Pediatrics, Danylo Halytskyy Lviv National Medical University, [3]Professor, Department of Pediatrics and Neonatology, Faculty of Postgraduate Education, Danylo Halytskyy Lviv National Medical University, Lviv, Ukraine

Background: Acute lymphoblastic leukemia is a frequent disease in childhood. An analysis of the efficacy of standard programs chemotherapy for ALL treatment is an important part of introducing new methods for treatment in the future.
Aims: Analysis of the results of 25 years treatment period of acute lymphoblastic leukemia (ALL) in children.
Methods: The results of the treatment from February 1993 to January 2018 according to the standard chemotherapy programs ALL-BFM'90/95, ALL IC-BFM2002, ALL IC-BFM2009, INTERFANT'99/06 were analyzed in 370 patients with ALL at the age from 0 to 18 years. The program "Statistica for Windows 8.0" (Statsoft, USA) was used for the above mentioned analysis. The function event-free survival (EFS) and overall survival (OS) from the first diagnosis to death for any reason is calculated by the Kaplan-Mayer method. Comparison of survival between groups – by using the Cox's-F-test.

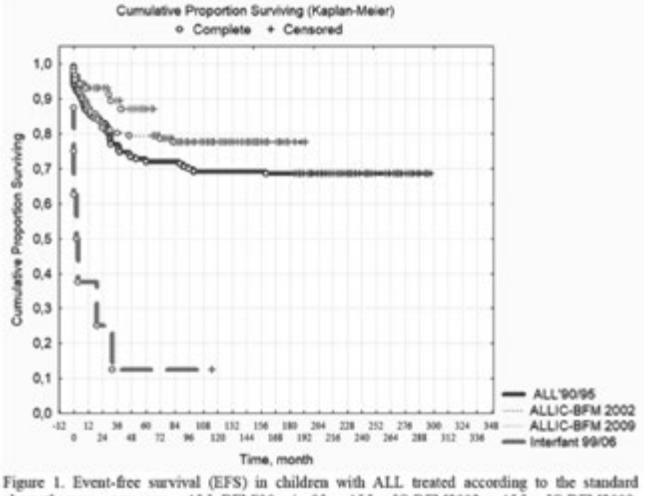

Figure 1. Event-free survival (EFS) in children with ALL treated according to the standard chemotherapy programs ALL-BFM'90 / 95, ALL IC-BFM2002, ALL IC-BFM2009, INTERFANT'99/06

Figure 1.

Results: From February 1993 to October 2002 143 (38,65%) patients received treatment based on programs ALL-BFM'90/95 (group 1); from November 2002 to June 2012-131 (35,41%) patients-ALLIC-BFM2002 (group 2); from June 2012-88 (23.78%) patients – ALLIC-BFM2009 (group 3) correspondingly. Children under the age of 1 year (8 persons) from August 2008 were treated according to INTERFANT'99/06 programs (group 4). EFS in group 1 is 68,0% with a median observation time (MO) for 219 months, in group 2-77,6% with MO 110 months, in group 3-85,2% with MO 38 months, in group 4-12,5% of MO 12,5 months (Figure 1). The sstatistically significant improvement of EFS indexes in group 3, the worst results in children under 1 y.o. ($p<0,05$) was found. The EFS for middle-risk group (MR) patients in the 1st group was 71,0%, in the 2nd group-83,7%, and in the 3rd group-90,5%. The EFS for the high-risk group (HR) patients in the 1st group was 50,0%, in the 2nd –55,6% and in the 3rd group-73,9%. The OS in the entire sample is 78,2%. The relapse of ALL was diagnosed in 53 (14,32%) persons. 34 (9,19%) children died, of which 11 patients (32,35%)-from septic complications before achieving remission of ALL, 19 children (55,88%)-from septic complications in the 1st remission during intensive chemotherapy, 1 HR-group patient-from post-transplant complications, 1 patient in long-lasting remission (160 months)-from the fulminant course of viral hepatitis B, two patients (5,88%) of secondary tumors. Secondary malignancy has been reported in 5 (1,35%) children. Astrocytoma, meningioma, secondary acute myeloid leukemia (AML) have been successfully treated, oligodendroglioma and secondary myelodysplastic syndrome with transformation in to AML was a reason of lethal consequence. 8 persons from the HR-group in the 1st remission had allo- (abroad), including 2 patients-for whom allo-BMT was a second therapeutic line for treatment of secondary AML.
Summary/Conclusion: The BFM international group's treatment programs of ALL show constantly increasing high effectiveness. Results of treatment in children of the first year of life are unsatisfactory and require improvement of therapeutic approaches. A rare, remote consequence of the treatment of ALL in children is secondary neoplasms, which should be kapt in mind by first-contact doctors and specialists.

PB1627

VENOUS THROMBOEMBOLISM IN PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL) TREATED WITH ERYASPASE (L-ASPARAGINASE ENCAPSULATED IN RED BLOOD CELLS)

Y. Bertrand[1,*], E. Radu[2], I. El-Hariry[2], R. Larson[3], D. Douer[4]

[1]CHU, [2]Erytech Pharma, Lyon, France, [3]University of Chicago, Chicago, [4]University of Southern California, Los Angeles, United States

Background: L-asparaginase (ASNase) is a key drug in the treatment of ALL. Its toxicity includes venous thromboembolism (VTE) which can be serious and potentially fatal. The reported prevalence of VTE among children and adults with ALL ranges between 1% and 37%. The rate is dependent on cofounding factors such as higher age, presence of indwelling venous catheters, the use of prophylactic antithrombin replacement or anticoagulation, inclusion of asymptomatic cases, and other risk factors unrelated to the use of ASNase. ASNase leads to serum asparagine depletion, inhibiting the synthesis of anti-coagulation factors such antithrombin III (AT), protein C, and protein S, which leads to increase in thrombin generation and risk of TE. ASNase is derived from *E. coli* (native or the long acting pegylated forms) or *Erwinia chyrsanthemi* bacteria. Eryaspase is an investigational product under development that uses a novel system to deliver native *E. coli* ASNase encapsulated within donor-derived matched red blood cells (RBCs) by a proprietary osmotic-based method. The aim is to improve the tolerance and prolong the activity of this enzyme. After eryaspase infusion, plasma asparagine is actively transported into RBCs, where it is hydrolyzed. As a result, asparagine in the plasma is depleted. ASNase activity of eryaspase is longer that the native *E. coli*. RBC encapsulation is done at GMP facilities in a process that typically takes 24 hours from obtaining donor-matched RBC to shipment of the product to the investigator's center. Eryaspase is delivered directly to the Investigator for immediate transfusion over 1 hour.
Aims: We are reporting on the occurrence of VTE after eryaspase treatment in patients with ALL, given the use of RBC and its distinct manufacturing process.
Methods: Integrated safety data from 5 studies of eryaspase in ALL were retrospectively analyzed using MedDRA coding. Treatment with eryaspase was in combination with chemotherapy during induction and consolidation phases. The cut-off date for analysis was 28 Feb 2017.
Results: A total of 125 patients were included in this series, with median age of 20 years (range, 2-77). Treatment was generally well tolerated. 8 (6.4%) patients (7 adults; one child) had VTE; 6 (4.8%) were serious events. VTE was considered related to eryaspase in 6 (4.8%) patients. The most common event was reported as venous thrombosis (n=6 (4.8%)). None of the events had a fatal outcome. Decreased AT was found in 35 (28%) of the patients. In a subset of patients randomized to eryaspase (n=26) or to native ASNase (n=28), laboratory coagulation abnormalities were observed in 11.5% and 71.4% during induction, respectively.
Summary/Conclusion: The risk of VTE with eryaspase treatment in our ALL patients was low and seen mostly in adults. The low incidence of these events may be related to decreased incidence of impaired coagulation parameters. We conclude that eryaspase is not associated with an increased rate or severity of VTE toxicity.

PB1628

TIROSINE KINASE REARRANGEMENTS IN PH-NEGATIVE ACUTE LYMPHOBLASTIC LEUKEMIA-A FISH APPROACH

T. Garrido*, M.J. Soares, A. Barbosa, M.L. Amorim, P. Gomes, F. Trigo, J.E. Guimaraes

Hospital Sao Joao, Porto, Portugal

Background: "Ph-like" acute lymphoblastic leukemia (ALL) is a subtype of B-cell precursor ALL characterized by a poor outcome and various kinase-activating alterations. These include rearrangements of *CRLF2*, *JAK2* or *EPOR*, fusions involving *ABL*-class genes, mutations activating *JAK-STAT* or *Ras* signaling pathways, and other less common fusions. There are reports that suggest that the poor outcome of these patients (pts) may be improved with Tirosine Kinase (TK) inhibitors.
Aims: In this study we aimed to identify genomic rearrangements of some of the most frequent key tyrosine kinase genes in Philadelphia chromosome-negative (Ph-) and BCR-ABL1–negative (-) ALL adult patients.
Methods: We selected 39 consecutive B-ALL adult patients out of 93 diagnosed in our centre from 2009 to 2017, all of which were Ph(-) and BCR-ABL1(-), without translocations involving 11q23 (*MLL* gene) detectable by conventional cytogenetics. Fluorescent *in situ* hybridization (FISH) analysis was performed using break apart probes for *CRLF2*, *ABL1*, *ABL2*, *JAK2* and *CSF1R* genes on the diagnostic samples. Retrospective analysis of patients' records was performed.
Results: Twenty-two (56.4%) pts were female, with median age at diagnosis of 41 years old [17; 71]; 19 (48.7%) were young adults (<40 years old). Ten (25.6%) pts had hyperleukocytosis (>30x10^9/L) and three (7.7%) had central nervous system involvement. Conventional cytogenetic analysis was successful in 31 patients: 22 (56%) had normal karyotype, 3 (9.7%) complex karyotype, 2 (6.5%) hyperdiploidy and 2 (6.5%) hypodiploidy. TK rearrangements were observed in 7 (18%) pts: 4 (10%) *CRLF2*, 2 (5.1%) *ABL1* and 1 (2.6%) *CSF1R*. No patient had *ABL2* or *JAK2* rearrangements. Of the 39 cases, 10 (27%) had copy number gains of one or more genes, including ABL2 and JAK2. None of the patients with TK rearrangements had complex or hypo/hyperdiploid karyotype. All patients were eligible for intensive chemotherapy protocols (31 HOVON100; 4 HyperCVAD; 4 CLGC). Thirty-three (84.6%) obtained complete remission (CR) after induction, 4 (10.3%) were refractory, and 1 patient died during induction. Sixteen (41%) pts proceeded to allogeneic stem cell transplantation, 14 in first CR. Ten (25.6%) pts relapsed and 15 (38.5%) died (5 in CR). Those patients with TK rearrangements (7) showed inferior median time-to-relapse (9 *vs* 34 months; p=0.003), 5-year disease-free survival (0% *vs* 65.1%; p=0.016) and 5-year overall survival (0% *vs* 66.5%; p=0.012).
Summary/Conclusion: Our study demonstrated that, among the Ph(-) ALL patients, those with TK rearrangements had inferior outcome. In a real life perspective, and in the absence of gene-expression profiling or next-generation sequencing, FISH analysis seems like a reliable and cost-effective screening method to identify known rearrangements probably responsible for unfavorable "Ph-like" behavior and potentially targetable with TK inhibitors.

PB1629

MANAGEMENT OF ADULT ACUTE LYMPHOBLASTIC LEUKEMIA WITH A PEDIATRIC-BASED REGIMEN: A SINGLE CENTER EXPERIENCE

P. Kaloyannidis*, N. Al Mokhtar, A. Sayyed, E. Shaibani, K. Bakhit, S. Al Harbi, R. Alomeri, O. Abduljalil, M. Abdulbaqi, S. Kanfar, M. Kawari, A. Suhebeh, J. Apostolidis, H. Al Hashmi, K. Al Anezi

Adult Hematology and Stem Cell Translantation Department, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Adult patients (pts) diagnosed with acute lymphoblastic leukemia (ALL), are considered to have dismal outcome compare to pediatric/adolescent pts. The last two decades the incorporation of pediatric therapeutic protocols in adults–ALL treatment, resulted in promising response and survival rates, however their use still remains an experimental approach, not representing the standard of care for adult-ALL pts.
Aims: In the present study we retrospectively evaluated the outcome in terms of toxicity, complete remission (CR) achievement and overall (OS) and progression free survival (PFS), in 52 adult-ALL pts adult pts who treated with a pediatric-ALL protocol.
Methods: From January 2008 to December 2017, the Children Cancer Group-1961(CCG-1961) protocol which includes Doxorubicin, Vincristin, Asparaginase, Methotrexate and Cytarabine in induction remission (InRe) and consolidation phases, was applied in 34 males and 18 females, with a median age of 21 (16-54) years. Patients with concurrent malignancies or severe co-morbitities were excluded. In 42 the malignant cells were B- and in 10 T-origin. Two pts had CNS involvement, 8 had >50000/mm^3 WBCs in the peripheral blood, while 11 found to have poor risk cytogenetic or molecular abnormalities. As per protocol instructions, candidates for allogeneic stem cell transplantation (alloSCT) considered only pts with either minimal residual disease (MRD) post InRe phase or relapsed disease. All patients received antibacterial, antiviral, anti-PCP and antifungal prophylaxis Disease response was assessed at day +28 after treatment initiation. The Kaplan-Meir and log-rank tests were used for the statistical analysis.
Results: Currently, 52 pts completed the InRe and consolidation arm and 11 are in ongoing treatment. Two pts discontinued early the treatment (during the consolidation phase) because of either severe liver toxicity or intolerable mucositis (grade4). The grade 3 observed toxicities, which did not compromise the treatment plan, were febrile neutropenia in 40 (75%), liver dysfunction (elevation of liver enzymes by 3-fold) in 32 (60%), peripheral neuropathy in 4 (7%), mucositis in 7 (14%), thrombosis in 6 (11%) which was mostly venous catheter related, cardiac toxicity in 3 (6%) while 7(14%) required admission in intensive care unit. No pt experienced mortality related to the treatment protocol. In a total 46 pts were evaluated for disease response while in 6 the assessment was not avaiable; 43 (85%) were estimated to be in CR. Three (6%) had refractory disease while 11(25%) relapsed during or after protocol completion; 5/14 succumbed early due to disease refractoriness and 9 were finally able to undergo alloSCT and currently 4/9 (45%) are alive and disease free. The 2 pts who experienced severe toxicity and intolerability during consolidation treatment, underwent early alloSCT and currently are alive and well. The 11 pts with unfavorable cytogenetic/molecular abnormalities, based on protocol instructions, were not allografted in CR1 and continued with the as per protocol scheduled treatment. Five (45%) are currently alive without disease evidence. The 10-years OS and PFS (including the alloSCT treatment) are 60% and 40% respectively.
Summary/Conclusion: Our study showed that the application of the CCG-1961 pediatric protocol in adult pts is feasible, offering CR rates of 85% and long term survival of 60%. However, its toxicity seems to be considerable. Prospective well organized trials with large series of patients are needed to define the role of intensive pediatric protocol in the treatment of adults-ALL.

PB1630

FEASIBILITY AND RESULTS OF BONE MARROW TRANSPLANTATION IN HIGH RISK ACUTE LYMPHOBLASTIC LEUKEMIA FOR CHILDREN AND YOUNG ADULTS

I. Frikha[1,*], M. Medhaffer[1], N. Ben Abdeljalil[2], S. Hdiji[1], I. Ben Amor[1], S. Laddab[2], F. Kallel[1], O. Kassar[1], M. Ghorbel[1], T. Ben Othmen[2], M. Elloumi[1]

[1]Hematology, Hedi Chaker Hospital, Sfax, Tunisia, Sfax, [2]Hematology, Bone Marrow Transplantation center, Tunis, Tunisia, Tunis, Tunisia

Background: The majority of children with acute lymphoblastic leukemia (ALL) can be definitively cured through the use of risk-oriented chemotherapy protocols. However, there are still subsets of children with ALL in whom the probability of survival with chemotherapy alone remains unsatisfactory, because of the high chance of disease recurrence. In this study, we analyzed the feasibility and results of allogenic stem cell transplantation for high-risk ALL of children and young adults.
Aims: In this study, we analyzed the feasibility and results of allogenic stem cell transplantation for high-risk ALL of children and young adults.
Methods: Between January 2000 and December 2015, 72 patients (27%) aged less than 30 years, with high-risk ALL in first complete remission treated with a frontline EORTC 58951 pediatric protocol, underwent allogeneic stem cell transplantation (HSCT). For these patients, we studied the indication of the allograft, the search of HLA intra-familial sibling donor, the feasibility and the results of the allograft performed at the National Center for bone marrow transplantation in Tunis.
Results: Seventy patients with high risk ALL were eligible for allogenic SCT. Among them 57 patients (81%) who realized the HLA study and 34 (60%) had at least one HLA-identical siblings donor. The allograft has been performed for only 18 patients (32%): 2 patients had relapsed before allograft, five patients had a severe infection with impaired general condition and the others patients had refused allograft SCT. With a median follow-up of 6 years, 11 allografted patients (61%) are still alive in complete remission (RC), 4 patients have relapsed (at 7, 9, 10 and 12 months). The transplant-related mortality was 17%. Among the 45 patients who were not allografts, 18 were living in CR (40%), 8 had died in post induction chemotherapy, and 17 had relapsed (38%).
Summary/Conclusion: In our study, despite the presence of HLA-identical siblings donor in 50% of cases, bone marrow allograft was proposed for only 28% of patients less than to Western series 60% of cases (HLA-identical sibling, a matched unrelated donor or cord blood). Allogenic stem cell transplantation in high risk acute lymphoblastic leukemia of child give interesting responses with 2/3 of patients are alive without relapse in our study, comparable to the literature (60 to 70% at 5 years). To further improve the

results, it is necessary to expand donor sources such as matched unrelated donor and cord blood transplantation.

PB1631

SUCCESSFUL ALTERNATIVE TREATMENT OF RELAPSED ADULT ACUTE LYMPHOBLASTIC LEUKEMIA WITH DENDRITIC CELLS CYTOKINE-INDUCED KILLER COMBINED WITH RITUXIMAB-BASED REGIMEN

J. Huang*, X. Xiao, X. Ye

Hematology, the Fourth Affiliated Hospital, College of Medicine ,Zhejiang University, Yiwu, China

Background: Relapsed ALL in adult carries a dismal prognosis despite intensive treatment.
Aims: In this report, successful alternative treatment containing rituximab and infusion of Dendritic cells-CIK is described in a case of early relapsed B cell ALL patient who could not tolerate intensive chemotherapy.
Methods: A 52-year-old man first presented with persisting fever and weakness in May. 2014. A blood test showed decreased levels of white blood cell($1.8*10^9$/L) and platelets ($63*10^9$/L). Bone marrow aspirate revealed 72 percent primitive blast cells, and immunophenotypic analysis showed that the blast cells expressed CD10, CD19, CD22, CD79a and human leukocyte antigen D–related. No cytogenetic abnormalities were detected by G-banding analysis. Similarly, MLL gene rearrangement, BCR/ABL1, ETV5/RUNX1 were also negative. Diagnosis of B-lymphoblastic leukemia NOS was made on basis of 2016 update revision of WHO classification criteria. The patient received VDCLP regimen consisting of vindesine, idarubicin, cyclophosphamide, asparaginase and dexamethasone. Finally, he achieved complete remission (CR) with 3.5% blast cells in bone marrow. However, severe side effects induced by induction therapy including febrile neutropenia, hyperglycemia and hepatic toxicity were followed. After high-dose methotrexate combined with asparaginase and MA consolidation therapy, neutropenia lasted for 2 months, during which he suffered pulmonary infection, sepsis and liver dysfunction. He refused to receive any maintenance therapy for significant complications.
Results: Six months later, the patient presented with fatigue and petechiae with a short CR1. Bone marrow with 31% blast cells was consistent with relapsed B cell ALL (CD19+, CD20+, CD10+, CD22+) (Fig). Treatment approaches for this patient in poor performance status is limited. DC-CIK was chosen as therapeutic choice. Subsequently, rituximab combined VDLP regimen was adopted, and he got second remission. Thereafter, four times consolidation therapy including rituximab were processed, during which seven cycles of DC-CIK cells infusion (each (4–6) × 109 CIK cells) were also accomplished. After that he received rituximab alone every 3 months for a year, and took thioguanine and methotrexate tablets at intervals of immunotherapy until March 11, 2017. Impressively, the patient has been in bone marrow remission for 30 months since last relapse.

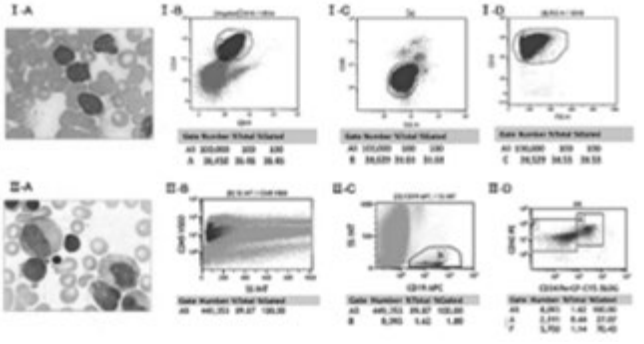

Figure 1.

Summary/Conclusion: High reinduction mortality, chemotherapy resistance and disease recurrent are impediments to successful management in relapsed ALL patients. The advantage of DC-CIK therapy is no adverse reactions, because CIK cells' anti-tumor activity is perforin mediated and various receptors were involved. Recent studies demonstrated that rituximab, anti-CD20 monoclonal antibody, may play a critical role in improvement of CIK-mediated cytotoxicity to leukemia cell. In this case, initiating DC-CIK therapy before chemotherapy help to improve the tolerability in patients with significant complications. To the best of our knowledge, it's the first report on DC-CIK combined with rituximab-based regimen for recurrent ALL. *Acknowledgment: The research was supported by funding of the Science and Technology Department of Zhejiang Province, China (2016C33160), and Yiwu public technology research projects, Zhejiang Province, China (2016-S-05). SERUM LEVELS OF CYTOKINES AND ADHESION MOLECULES IN NEWLY DIAGNOSED B-CELL PRECURSOR ACUTE LYMPHOBLASTIC LEUKEMIA AND IN COMPLETE REMISSION, AND THEIR ASSOCIATION WITH OVERALL SURVIVAL

J.M. Horacek[1,2,*], T. Kupsa[1,2], J. Vanek[3], L. Jebavy[1,2], P. Zak[2]

[1]Department of Military Internal Medicine and Military Hygiene, University of Defence, Faculty of Military Health Sciences, [2]Department of Internal Medicine IV-Hematology, University Hospital and Charles University, Faculty of Medicine, [3]Department of Informatics and Quantitative Methods, University of Hradec Kralove, Faculty of Informatics and Management, Hradec Kralove, Czech Republic

Background: Dysregulated production of cytokines and adhesion molecules has been implicated in the onset and progression of various types of leukemia. Further knowledge gained from multiple cytokine and adhesion molecule evaluation could help to improve treatment outcomes.
Aims: The aim of this study was to evaluate serum levels of selected cytokines and adhesion molecules in newly diagnosed B-cell precursor acute lymphoblastic leukemia (B-ALL) and in complete remission, and their association with overall survival.
Methods: A total of 40 newly diagnosed B-ALL patients (median age 49, range 19–75 years, 27 males) were included in this study. Serum samples were taken at diagnosis and in complete remission. We evaluated serum levels of 12 cytokines and 5 adhesion molecules. From cytokines, we measured Interleukins (IL-1α, IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10), Interferon-γ (IFN-γ), Tumour Necrosis Factor-α (TNF-α), Epidermal Growth Factor (EGF), Vascular Endothelial Growth Factor (VEGF) and Monocyte Chemotactic Protein-1 (MCP-1). From soluble adhesion molecules, we measured E-Selectin (E-SEL), L-Selectin (L-SEL), P-Selectin (P-SEL), Intercellular Adhesion Molecule-1 (ICAM-1) and Vascular Cell Adhesion Molecule-1 (VCAM-1). All analytes were measured by biochip array technology on Evidence Investigator analyzer (Randox). Correlations between analytes and overall survival were evaluated separately in both clinical situations. Statistical evaluation was done by a professional statistician using software R 3.4.3 (R Core Team 2017). Probability values (p)<0.01 were considered statistically significant.
Results: At diagnosis of B-ALL, we found significantly higher levels of IL-6, IL-8, IL-10, TNF-α, E-SEL, L-SEL, ICAM-1, VCAM-1 ($p<0.01$) and significantly lower levels of EGF, P-SEL ($p<0.01$) in comparison with complete remission. Serum levels of other evaluated analytes were without significant differences. In complete remission, EGF correlated with P-SEL ($r=0.755$; $p<0.001$) and IL-1α with IL-4 ($r=0.612$; $p=0.007$). Other correlations between analytes did not reach statistical significance. Inferior overall survival was associated with higher IL-2 level at diagnosis ($r=0.448$; $p=0.003$) and higher L-SEL levels in complete remission ($r=0.410$; $p=0.001$).
Summary/Conclusion: Conclusion: Our results show that serum levels of some cytokines and adhesion molecules are significantly altered in newly diagnosed B-ALL, reflecting activity of the disease. In our cohort of B-ALL patients, we found statistically significant correlations between inferior overall survival and higher IL-2 levels at diagnosis and higher L-SEL levels in complete remission. Better understanding of leukemia microenvironment is essential for development of new treatment approaches. Further studies in this field are warranted. This work was supported by a long-term organization development plan 1011 (FMHS) and by program PROGRES Q40/08.

PB1633

EPIDEMIOLOGICAL EVALUATION, MANAGEMENT AND OUTCOME OF ACUTE LYMPHOBLASTIC LEUKAEMIA PATIENTS AGED MORE 65 YEARS IN A REAL LIFE SETTING. A SINGLE CENTER EXPERIENCE

E. Borlenghi[1,*], F. Schieppati[1], A. Passi[1], C. Cattaneo[1], E. Cerqui[1], V. Orlando[1], M. Sciumè[1], A. Sottini[2], G. Rossi[1]

[1]Hematology, [2]Laboratorio CREA, Spedali Civili, Brescia, Italy

Background: Acute Lymphoblastic Leukaemia (ALL) is considered rare in elderly patients (pts) but its frequency may be increasing, particularly due to the longer life expectancy of the general population. Management of

older pts is an unmet medical need. Significantly lower rates of complete remission, higher early mortality and poorer survival are observed in older compared with younger pts (Gokbuget, 2017). The potential benefit of using moderately intensive chemotherapy protocols for Ph/BCR-ABL-negative ALL and the combination of tyrosine kinase inhibitors (TKI) with chemotherapy in Ph/BCR-ABL positive ALL is debated.
Aims: To analyze the frequency, characteristics and outcome of older pts with ALL consecutively diagnosed at a single Institution receiving treatments of different intensity.

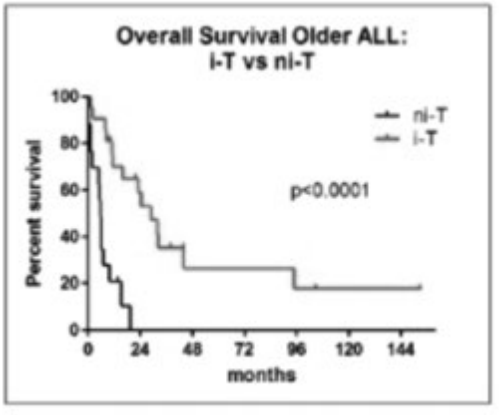

Figure 1.

Table 1.

	total	ni-T	i-T	P (Fisher exact test)
Pts number	38	17	21	
Age (median)	73 (65-88)	75 (71-88)	70 (65-79)	ns
Performance status ECOG > 2	16/38 (42%)	9/17	5/21	0.09
CR n° (%)	27/38 (71)	8/17 (47%)	19/21 (90)	0.0049
Relapse n° (%)	62.9%	6/8 (75%)	9*/19 (47.3%)	ns
Median survival mo (range)	11.1 (1-153)	5,7 (1-15)	29 (1-153)	<0.0001
			*2/9 molecular relapse	

Methods: Of 172 ALL pts diagnosed at our Institution between Jan 2000 to Dec 2017, 38 were ≥65 y old (22%). Median age was 73 y (65-88), F/M was 17/19, performance status according to ECOG was 2 in 13 pts and 3 in 14 pts. Molecular analysis, including AF4/MLL and BCR/ABL transcripts (Ph+), were performed in all pts and karyotype was available in 30 (78.9%). According to clinical judgement, age and molecular status pts received intensive treatment (iT) defined as dose-adjusted chemotherapy (da-CT), + TKI in Ph+ (NILG protocols) (Bassan 2015), or non intensive treatment (niT) *i.e.* steroids, best supportive care (BSC), + TKI alone in Ph+ pts.
Results: According to the year of diagnosis, the number of elderly ALL pts has increased. Between Jan 2000 and Dec 2008, a lower rate of ALL in pts aged ≥65 was observed, compared to the time period Jan 2009-Dec 2017 (6/66, 9% *vs* 32/106, 30.2%, respectively)(p0.001 chi-squared test). According to phenotype, 32 were B-ALL (84.2%), 1 mixed-phenotype (My-ALL) and 5 (12.8%) were T-ALL/lymphoblastic lymphoma. Two pts showed AF4/MLL rearrangements and 14 were BCR/ABL positive, with e1a2 or b3a2 transcript in 10 and 4 pts, respectively. Karyotype was normal in 7 pts, high hyperdiploidy (He) or near triploidy (Ho-Tr), chromosomal translocations [t(9;22) and t(4;11)] and chromosomal deletions were detected in 4, 16 and 3 pts, respectively. ECOG was >2 in 9/17 niT pts *vs* 5/21 iT pts (p0.09 Fisher's exact test). Complete remission and relapse rate were 71% (27/38) and 62.9% (17/27), respectively. Median follow-up of the whole elderly population was 30.5 months (mo) and median survival was 11.1 mo. The main cause of death was disease progression (22/28, 78.6%); other causes were: cardiac (2), myelodysplasia (1), strongyloides infection (1), hepatic failure (1), unknown (1). The characteristics and outcome of iT and niT are summarized in Table 1 and in Figure 1. In particular, median survival of ALL Ph- iT pts was 23,3 mo (1-105 mo) compared to ni-T pts (2 mo, 1-9) (p<0.0001, log-rank test) and median survival of ALL Ph+ iT pts (TKI+da-CT) was 32.4 mo (8-153) compared to ALL Ph+ niT (TKI alone) (6.8 mo, 2-15)(p 0.014 log-rank test). Autologous stem cell transplantation (ASCT) was performed in 7 pts, 4 Ph+ and 3 Ph- (1 MLL/AF4, 1 T-ALL, 1 with HoTr K). Five pts were in molecular CR at the time of ASCT (4 Ph+ and 1 MLL/AF4), two pts were in cytogenetic CR, not available molecular data.
Summary/Conclusion: A non-negligible number of pts is diagnosed with ALL over the age of 65, with an incidence that is progressively increasing (27.5% of ALL population). In our experience, intensive treatment including da-CT with TKI in Ph+ pts with or without ASCT was feasible and tolerated, also in a population-based setting, and improved survival both in Ph- but also in Ph+ ALL pts.

PB1634

SPECTRUM OF ASPARAGINASE-INDUCED ADVERSE REACTIONS IN PEDIATRIC PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

M. Elshinawy[1,2,*], A. Al Rawas[1], Y. Wali[1]

[1]Pediatric Hematology, Sultan Qaboos University Hospital, Muscat, Oman, [2]Pediatric Hematology, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: Asparaginase is an essential drug for treatment of pediatric acute lymphoblastic leukemia (ALL). It acts by enzymatic cleavage of L-asparagine amino acid into aspartic acid and ammonia, thus depriving the leukemic cells from L-asparagine, resulting into cell death. Three preparations are available; the native asparaginase derived from *Escherichia coli (E. coli*-asparaginase), a pegylated form (PEG-asparaginase) and a product isolated from *Erwinia chrysanthemi, i.e.* Erwinia asparaginase. Owing to its easier administration and less frequent injections, our patients receive PEG-asparaginase as a standard of care.
Aims: To review the clinical presentations, radiological characteristics, management and prognosis of asparaginase-related adverse reactions in Omani children with ALL.
Methods: A retrospective cohort study of all children diagnosed with ALL who developed asparaginase-induced adverse effects while being on chemotherapy during the period January 2006 through January 2018.
Results: Out of 198 pediatric patients with ALL, 11 children (8 males and 3 females) developed severe asparaginase-related adverse effects, constituting 5.6% of the total number of patients. Severe full blown pancreatitis was encountered in only one patient (0.05%). He is an 11 year-old male which has survived this stormy mishap, but developed permanent diabetes mellitus that required lifelong insulin therapy. He has never been exposed to any further doses of asparaginase, and then went into complete remission. Two patients developed severe anaphylactic reaction, and then shifted to erwinia asparaginase with no recurrence. Notably, eight of our patients developed asparaginase-related cerebral venous sinus thrombosis, evidenced by contrast-enhanced cerebral MRI. The mean duration of stroke diagnosis was (6±2.1) days after the last asparaginase injection. All were managed conservatively with anticoagulation using unfractionated and/or low molecular weight heparin. Two of these patients have had a recurrence upon re-challenge, despite concomitant prophylactic heparin. Remarkably, seven patients (7/8) survived without any neurological sequelae. Unfortunately, a 30 month-old boy developed permanent right-sided hemiplegia secondary to extensive superior sagittal sinus thrombosis, which has been uniquely associated with massive left-sided fronto-parietal hemorrhage and midline shift (Figure). This patient required ICU admission and underwent a pressure-relieving craniectomy surgey. It has been planned not to expose him to any further asparaginase doses. In addition to these severe reactions, 23 patients developed mild to moderate asparaginase-related side effects in the form of transient hyperglycemia that required insulin therapy in 17 patients, local skin reaction at the site of injection in 3 patients and transient urticarial skin rash in 3 patients as well.

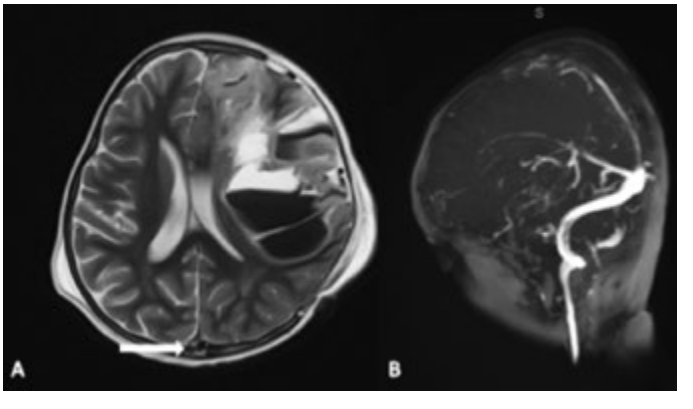

Figure 1.

Summary/Conclusion: Most of asparaginase-induced adverse reactions are transient and self-limited. However, a high index of suspicion is needed for early detection of intracranial thrombotic complications. Contrast-enhanced

magnetic resonance venography (MRV), or CT venography are the modalities of choice. Early diagnosis, discontinuation of asparaginase and prompt initiation of anticoagulation are mandatory steps to prevent permanent neurological deficits.

PB1635

FLOW CYTOMETRIC MINIMAL RESIDUAL DISEASE DETECTION IN B-ACUTE LYMPHOBLASTIC LEUKEMIA: EVALUATION OF TWO COMMERCIAL KITS

A. Ahn[1,*], C.-J. Park[1], Y.-U. Cho[1], S. Jang[1], E.-J. Seo[1], H. Kim[2], K.-N. Koh[2], H.-J. Im[2], J.-J. Seo[2]

[1]Department of Laboratory Medicine, [2]Department of Pediatrics, University of Ulsan College of Medicine and Asan Medical Center, Seoul, Korea, Republic Of

Background: Minimal residual disease (MRD) is an important independent prognostic factor that can identify poor responders among patients with B-acute lymphoblastic leukemia (ALL). The fundamental principle of the detection of MRD by flow cytometry is that leukemic cells show altered patterns of antigen expression. There are ongoing efforts to standardize MRD quantification using flow cytometry to improve accuracy and reproducibility, because hematogones that may morphologically resemble the leukemic cells of B-ALL are often increased in regenerating marrow following chemotherapy or hematopoietic stem cell transplantation.
Aims: The aim of this study was to evaluate two commercial kits for flow cytometric MRD detection in B-ALL.
Methods: 50 bone marrow aspirates with less than 5% leukemic cells by conventional morphology from treated 30 pediatric patients with B-ALL were obtained. MRD was measured using two commercial kits for flow cytometeric MRD detection; DuraClone RE ALB Tube (Beckman Coulter, Miami, USA) and BCP-ALL-MRD (Cytognos SL, Salamanca, Spain). The main methodological approach for detecting MRD is to detect antigen over or under expression of DuraClone RE ALB Tube (CD58/CD34/CD10/CD19/CD38/CD20/CD45) and aberrant expression of BCP-ALL-MRD (tube1: CD20/CD45/CD81/CD66c+CD123/CD34/CD19/CD10/CD38, tube2: CD20/CD45/CD81/CD73+CD304/CD34/CD19/CD10/CD38). Acquisition cell numbers of DuraClone RE ALB Tube and BCP-ALL-MRD were $2.0x10^6$ and $5.0x10^6$, respectively. Flow cytometric analysis was performed by manual serial gating according to our protocol. All specimens for MRD detection were negative for by real-time quantitative polymerase chain reaction (RQ-PCR) or fluorescence *in situ* hybridization (FISH) according to genetic abnormalities at diagnosis except 4 bone marrow aspirates (minor *BCR-ABL1* RQ-PCR: positive, normalized copy number: 13.41, 1.25, and 0.25 and% cells with *MLL* deletion, *RUNX1* gain, and *IGH* gain by FISH: 0.50-0.75%).

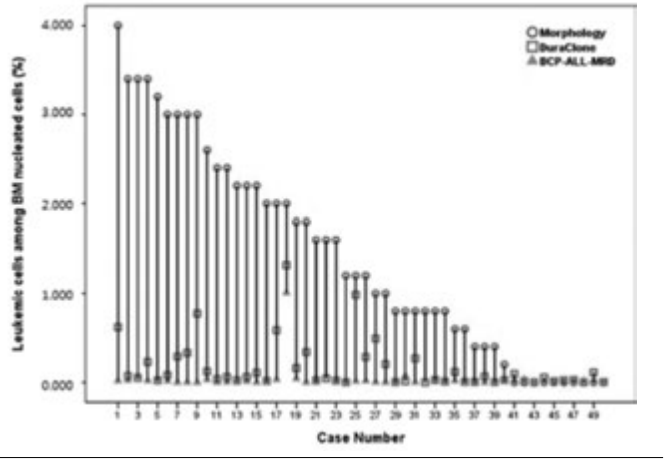

Figure 1.

Results: The median patient age was 7 years (range, 3-20) and the ratio of boy to girl was 1:1. The median time of sample collection was 153.5 days (14-3930) after diagnosis or relapse. The immunophenotype of leukemic cells at diagnosis in all patients showed CD10 positive (cutoff ≥20%) and variable CD34 and CD20 expression. Leukemic cells at diagnosis were all positive for CD58 but variable CD38 expression from negative to bright positive. Aberrant expression at diagnosis was CD66c (13/24, 54%), CD123 (12/24, 50%), CD73 (8/24, 33%), CD304 (1/24, 4%), CD13 (5/29, 17%), CD33 (3/29, 10%), and CD56 (1/29, 3%). The leukemic cell% (mean±SD) were 1.4±1.2% by conventional morphology, 0.166±0.268% by DuraClone RE ALB Tube and 0.034±0.143% by BCP-ALL-MRD (Fig.1, P=0.001 in difference). MRD% by DuraClone RE ALB Tube and BCP-ALL-MRD were well correlated ($P \leq 0.001$). However, the percentage of leukemic cells by conventional morphology show statistical significance with MRD% by DuraClone RE ALB Tube, but not with BCP-ALL-MRD (P=0.024 and P=0.521, respectively).
Summary/Conclusion: Detection of MRD in patients with B-ALL is limited by conventional morphology. For the flow cytometric detection of MRD in B-ALL, the kit detecting antigen over or under expression was adequate, but the kit detecting aberrant expression showed significantly lower level of MRD. It is very helpful for analysis of MRD to know the immunophenotype of leukemic cells at diagnosis.

PB1636

EFFECTS OF IRON OVERLOAD IN CHILDREN WITH ALL

K. Bruslova*, N. Tsvietkova, L. Honchar, S. Iatsemyrskii

Radiation Hematology for Children, SI "National Research Center for Radiation Medicine of NAMS of Ukraine", Kiev, Ukraine

Background: Iron overload of the body is associated with the risk of development of malignant hematologic pathology and frequency of complications in children with ALL and is one of the causes of patients death.
Aims: The goal is to determine the association of serum ferritin (SF) levels in the debut of ALL in children with the nature of complications, the development of relapses and the prognosis of disease course.
Methods: Serum ferritin (SF) has been determined and anemia has been identified in 146 children with ALL before chemotherapy, as well as in the treatment stages. The analysis of obtained data taking into account the ALL variant, presence of complications (bacterial infections, toxic hepatitis, etc.), number of RBC transfusions during treatment, development of resistance to chemotherapy and the number and nature of ALL relapses. Morphological evaluation of dyserythropoiesis manifestations in bone marrow elements was executed and parametrs of porphyrin metabolism (aminolevulinic acid and porphobilinogen) were studied.
Results: Distribution of 146 patients with ALL was performed by initial SF (before start of treatment) levels: up to 200ng/mL had 53 patients (36.3%); from 200 to 500ng/mL, normal-49 (33.6%); more than 500ng/mL-44 (30.1%). Anemia was not found in 15.7% of patients. Anemia with normal SF was found in 41.1% of patients, anemia with low SF in 15.9%, and with SF in 27.4%. More patients with iron excess had pro-B-ALL, smaller number of iros excess children suffered from common- ALL variant (rs=0.48). Bacterial infections were common for patients with SF higher than 200ng/ml, toxic hepatitis and chemotherapy resistance were found more frequently at SF levels higher than 500ng/ml (rs=0.48). The number of erythrocyte transfusions correlated with the development of relapse in children (rs=0.46). There is direct correlation between SF level and the presence of bone marrow relapse in patients (rs=0.44). In cases with SF levels above 500ng/mL, the percentage of sideroblasts and manifestations of dyserythropoiesis were higher in patients with ALL relapses or unfavorable disease course. Excess of iron may be the result of ineffective erythropoiesis, endogenous erythropoietin deficiency, reactive oxygen species levels incrising, and transfusion therapy.The removal of excess iron (reduction of serum ferritin) occurred gradually during the treatment and follow-up of patients, taking into account the established causes. The mean value of SF level before treatment was 784.4ng/mL, after-158ng/mL. Light microscopic examination of the bone marrow revealed increased iron granules in erythroblasts, dyseritropose phenomena.
Summary/Conclusion: The results of the studies have shown that iron overload is a severe complication of ALL. Particular attention is paid to the presence of high initial levels of SF in patients before treatment, the development of complications and the substitution of erythrocytic transfusions, which should be considered as a risk factor for development and unfavorable prediction of ALL course in children.

PB1637

THE TREATMENT OUTCOME OF CHILDREN WİTH ACUTE LYMPHOBLASTIC LEUKEMIA: 20 YEARS EXPERIENCE FROM A SINGLE CENTER IN TURKEY

A. Meral Güneş[1,*], M. Sezgin Evim[1], B. Baytan[1], M. Ertekin[1], S. Güler[2], U. Aygüneş[3]

[1]Departmant of Pediatric Hematology, Uludağ university, Bursa, [2]Pediatric

Hematology, Konya State Hospital, Konya, [3]Pediatric hematology, cumhuriyet University, Sivas, Turkey

Background: Acute lymphoblastic leukemia (ALL) is a malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic marrow cell.
Aims: We retrospectively evaluated the treatment results of children with de nova ALL treated with BFM ALL (1990-1995-2000-2009) protocols between the years 1993 and 2017.
Methods: The overall (OS) and event free (EFS) survivals according to age, initial leukocyte count, immunophenotype, chemotherapy responses (on days 8, 15, and 33), and risk groups were analyzed by Kaplan-Meier survival analysis by SPSS 2009. In total ,MRD(minimal residual disease) analysis was avaliable in 33% (n=141)of children either with flowcytometry or PCR.
Results: The data of 460 children diagnosed as de nova ALL were retrospectively evaluated. Male (291)/Female (169) ratio was: 1.7 and median age was 6.9 years (0.5-17.8). Median follow-up time was 7,7 years. (1-297 months). Children were classified as high risk (28%), medium risk(60.2%), and stantard risk(9.3%) groups.Relapse time was defined according to BFM definition. (Late relapse >30 months, early relaps 18-30 months and very early relapse <18 months from the initial time of diagnosis) Complete remission was achieved in 97% of children. EFS and OS at 5 years were found 78.8 and 82.3%, respectively. Children younger than 6 years old had better EFS and OS (83.7 and 85.2%) than children aged ≥6 years (71.4 and 72.8%)(p=0.23). Patients who had initial leukocyte counts of<20×10^9/L had better EFS and OS (80.6 and 84%) than children with higher initial leukocyte counts (76 and 80.2%)(p=0.22). The majority of the patients were B cell (80.2%) and the rest were T cell ALL(19.8%). EFS for B and T-cell ALL was 84.3 and 76.4%, respectively(p=0.128). Children with a prednisolone good response on day 8 (83,5%) achieved significantly better EFS and OS (80.3 and 84.6%) *vs* (71.2 and 71%)(p=0.025). n children whose bone marrow on day 15 m1 and m2 bone marrow (M1 and M2 bone marrow) had also higher EFS and OS (82.8 and 85.9% *vs* 71 and 77.5%) (p=0.001)than the childrem with m3. Children in the standard-risk and medium-risk groups obtained significantly higher EFS (88.4 and 81.5%) OS (90.7 and 86.6%) compared to the high-risk group (EFS 75.6%, OS 76.6%)(p=0.001). The relapse rate was found 18%. The median relapse time from diagnosis was 29 months.(3-129). Late relapses had higher OS (33.3%) than very early and early relapse cases (15%), respectively (p=0.003). Death occurred in 82 of 460 patients (17.8%). The major causes of death were neutropenic sepsis and relapse disease.
Summary/Conclusion: The high survival rate with BFM based ALL protocols were obtained in our center.These protocols can be succesfully applied in treatment of childhood leukemia in countries with limited sources.

PB1638

ALLOGENEIC STEM CELL TRANSPLANTATION FOR PHILADELPHIA POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

H. Bouarab*, M. Benakli, S. Zerkout, K. Tarhi, F. Mehdid, N. Rahmoune, D. Ait Ouali, M. Baazizi, R. Belhadj, F. Harieche, R.-M. Hamladji, R. Ahmed Nacer

Hematology and Bone Marrow Transplantation, Pierre and Marie Curie Center, Algiers, Algeria

Background: Patients (pts) with Philadelphia-positive acute lymphoblastic leukemia (Ph+ ALL) in first complete remission (CR) are at risk because chemotherapy alone does not allow long-term survival. Hematopoietic stem cell transplantation (HSCT) is considered the most potent post-remission antileukemic therapy.
Aims: We report in this series results of this procedure in 31 pts with Ph+ ALL.
Methods: From January 2012 to December 2016, 31 pts with Ph+ ALL were treated with HSCT (24 sibling HLA-identical, 06 haplo-identical and 01 syngeneic). Twenty four pts (77%) received a tyrosine kinase inhibitor (TKI) during induction therapy. The disease status at transplant: first CR (23 pts), 2nd CR (07 pts), blast phase (01 pt) of whom 16 pts (51%) were in molecular remission. The median age is 29 years (06-49), of whom 08 (32%) are under 18 years of age. The sex ratio is 1.81. The average of last remission-transplant was 4 months (01-12). All pts received chemotherapy conditioning: BAM12 protocol (13 pts) associating Busilvex (dose according to weight in children, 12.8mg/kg in adults), Aracytine 12g/m^2 and Melphalan 140mg/m^2; the TUTSHKA-VP16 protocol (10 pts) associating Busilvex, Endoxan 120mg/kg and Etoposide 15mg/kg; SANTOS protocol (02 pts) associating Busilvex and Endoxan 200mg/kg. Six pts beneficied haplo-identical HSCT including 05 pts with a Chinese protocol combining Busilvex 9.6mg/kg, Aracytine 08g/m^2, Endoxan 3.6g/m^2 and Thymoglobulin 10mg/kg; one pt received a TBF protocole combining Busilvex (9.6mg/kg), Fludarabine (150mg/m^2) and Thiotepa (10mg/kg). All pts received a peripheral blood stem cell transplant obtained after mobilization with G-CSF alone with the average CD34+ cell count 9.88. 106/kg (4.1-41). An additional bone marrow transplant G-CSF primed was used in the 5 pts in haplo-identical HSCT with an average of nucleated cells 5.67. 108/kg (0.5-10.7). GVHD prophylaxis associated Cyclosporine-Methotrexate for sibling HLA-identical HSCT; Cyclosporine-Methotrexate-Cellcept for haplo-identical HSCT (Chinese protocole); Cyclosporine-Cellcept and post-transplantion cyclophosphamide (TBF protocol) and without prophylaxis (syngeneic HSCT). TKI was instituted as prevention for relapse from 3 months after transplant in 21 pts (76%). At December 2017 the minimal follow-up delay is 6 months and the maximal 60 months.
Results: The median duration of aplasia is 15 days (09-29). Neutrophils engraftment was obtained at day 15 (11-29). Transfusions were required with an average of red blood cells: 2,4 units/pt and Platelets concentrates: 1,8 units/pt. No pt showed rejection, VOD or haemorrhagic cystitis. Acute GVHD was observed in 08 pts (25%), including 07 grade III-IV, and chronic GVHD occurred in 07 pts (29%), of which 03 were extensive. CMV reactivation was observed in 08 pts (25%) on average day 46 (28-69). Relapse occurred in 12 pts (38%) within an average of 11 months (3-32) of which 10 pts was in TKI post-transplantation. At December 2017, 17 pts died, of which 08 related to the procedure (TRM: 25%, GVHA 07 pts, acute pancreatitis 01 pt) and 09 pts of relapse. Fourteen pts are alive in complete remission with a median follow-up of 28 months (06-50), including 13 in molecular remission. Overall survival and event-free survival at 57 months are 26.7% and 24.2% respectively.
Summary/Conclusion: Results of HSCT in pts with Ph+ ALL have to be improved. The addition of TKI as a preventive treatment for post-transplant relapses has not been beneficial in our series.

PB1639

THE OVERALL SURVIVAL (OS) OF PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL), DEPENDING ON THE INCLUSION IN CLINICAL TRIAL: THE ACUTE LEUKEMIA (AL) REGISTER AND THE CLINICAL STUDY "ALL-2009"

Z. Akhmerzaeva[1,*], S. Kulikov[1], Y. Chabaeva[1], E. Zotina[2], L. Gavrilova[3], A. Pristupa[4], N. Vopilina[5], E. Borisenkova[6], E. Parovichnikova[1]

[1]National Research Center for Hematology, Moscow, [2]Kirov clinic hospital, Kirov, [3]Mordovia republic hospital, Mordovia, [4]Ryazan regional clinical hospital, Ryazan, [5]Tambov regional clinical hospital, Tambov, [6]Kaluga regional clinical hospital, Kaluga, Russian Federation

Background: Several clinical and population studies have shown a significant impact of the inclusion of patients with AL in clinical studies on their overall and disease-free survival (DFS). In Russia, such data on the effect of inclusion in clinical trials on the effectiveness of therapy for patients with AL are not available yet.
Aims: Evaluation of OS patients with ALL depending on the inclusion in clinical trials in 5 regions of the Russian Federation according to the AL Register and the clinical study "ALL-2009" (NCT 01193933).
Methods: The AL Registry was conducted since Apr 2009 till Dec 2016. 333 AL cases from Kirov, Ryazan, Kaluga, Tambov regions and Mordovia republic were included into analysis. The Russian multicenter "ALL-2009" trial was conducted since Apr 2009 till Dec 2016 and included 330 Ph-negative ALL patients with a median age 28 y (15-55).
Results: The distribution by AL subtypes was following: AML-251 (75,3%), ALL-58 (17,4%), APL-19(5,7%), other-5 (1,5%). Median age was for AML-59y (17-85), ALL-38y (16-80), APL 51y (21-79) years. Gender female/male proportions 184/149. As the "ALL-2009" study had the inclusion criteria of age<55years, among 42 AL Registry patients under the age of 55 years, 20 were registered in the "ALL-2009" study. 22 patients, not included in the study due to comorbidity, were nontheless treated by the same protocol. 16 older patients received deescalated therapy. The 3-year OS of all ALL patients was 47% (median 27.6 months). The 3-year OS with ALL in the group of patients younger than 55 years was 51% (median 27 months); older than 55 years-27%; (median 5 months) (p=0.29). OS in patients from the AL Registry, included in "ALL-2009" study (n=22), constituted 58%. In patients not included in the "ALL-2009" study, but treated according to this protocol (n=20), the 3-year OS was slightly lower-47% than in the patients formally included in the study (p=0.68). OS of ALL patients, depending on the treatment center, differed significantly. OS in federal institutions and regional centers-61% *versus* 46%, respectively (p=0.003).
Summary/Conclusion: OS of ALL patients included and not included in the "ALL-2009" study, but treated according to the protocol, did not significantly differ. This fact demonstrates good reproducibility and effectiveness of treatment protocol. It was shown that the hematological hospital where

the treatment was administered became an independent significant prognostic factor for survival of AL patients.

PB1640

TOLERABILITY OF PEGYLATED L-ASPARAGINASE IN ADULT ACUTE LYMPHOBLASTIC LEUKAEMIA: A SINGLE CENTRE EXPERIENCE

R. Lyne[1,*], J. Allan[2], M. Drummond[3], R. Soutar[4]

[1]Medical School, University of Glasgow, [2]Pharmacy, [3]Haematology, Beatson West of Scotland Cancer Centre, [4]Haematology, University of Glasgow, Glasgow, United Kingdom

Background: Overall survival in Adult Acute Lymphoblastic Leukaemia (ALL) has improved with time, the drug L-Asparaginase is an essential component in ALL treatment protocols, both in paediatrics and adults.
Aims: Compared to paediatric patients, adult patients tolerate intensive chemotherapy regimens less well. This audit investigated the use of PEGylated L-Asparaginase (PEG-L-ASP) in adult ALL chemotherapy regimens and its adverse effects, namely: hepatotoxicity, pancreatitis and hypertriglyceridemia.
Methods: Thirteen patients in the UKALL14 trial and nine in the UKALL2011 trial were studied by case note review retrospectively. These groups allowed age comparison: 30-55 years (UKALL14) and 17-24 years (UKALL2011). Toxicity gradings were calculated using the Common Terminology Criteria for Adverse Effects v4.0 (US Department of Health and Human Services, 2009).
Results: Overall the older patients had higher hepatotoxicity gradings than the younger patients (see Table). More critically, none of the older cohort could complete their proposed schedule because of PEG-L-ASP related toxicity compared to 78% of the younger cohort.

Table 1.

CTCAE Toxicity Gradings			
		Ages 17-24 (9 patients)	Ages 30-55 (13 patients)
Bilirubin Toxicity	Grades 1+2	6	9
	Grade 3	3	2
	Grade 4	0	2
ALT Toxicity	Grades 1+2	2	4
	Grade 3	6	8
	Grade 4	1	1
AST Toxicity	Grades 1+2	5	6
	Grade 3	4	6
	Grade 4	0	0
Mean Toxicity		2.2	2.4

Summary/Conclusion: This audit demonstrated significant toxicity of PEG-L-ASP in patients aged greater than 30 years. Toxicity of PEG-L-ASP has previously been noted in Ph positive adult ALL patients undergoing therapy. Treatment delays are very undesirable in the treatment of ALL. Alternative therapy with non-PEG-ylated L-Asparaginase allows for drug withdrawal if toxicity occurs because of its shorter half life. However, PEG-L-ASP has shown to be beneficial in paediatric and adolescent ALL protocols because of its faster asparagine depletion and more prolonged effects. While the optimum form of L-Asparaginase to use in older adult patients remains under investigation, our clinical practice in light of our findings, has been to revert to conventional asparaginase (Erwinia) in adult patients over 30 years old.

PB1641

A REPORT OF DIFFERENT PURPOSES: BLINATUMOMAB WITH PREVIOUS DEBULKING CHEMOTHERAPY TO REACH OR MAINTAIN RESPONSE

G. Ferrer Garrido[1,*], L. Costilla Barriga[1], B. De Rueda Ciller[1], C. Rodríguez-Vigil Iturrate[2], M. Villalba Montaner[1], E. Salvador Rupérez[1], P. Delgado Beltrán[1]

[1]Hematología clínica, [2]Oncopediatría, Hospital Universitario Miguel Servet, Zaragoza, Spain

Background: Blinatumomab is a bispecific T-cell antibody indicated for the treatment of adult and pediatric patients with Philadelphia chromosome-negative (Ph-) relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL).

Aims: We report 2 cases of response reach and maintenance to blinatumomab.
Methods: Case 1: A 21 years old man who presented peripheral blood (PB): leukocytes 2.4 x 10 3/µL, neutrophils 0.9 x 10 3/µL, hemoglobin 9.7 g/dL, platelets 22 x 10 3/µL. Lymphoblasts 1%. The bone marrow aspirate (BMA) with 35% of lymphoblasts. The immunophenotype (IF) (Table 1), cytogenetic and molecular biology analysis confirmed the diagnosis of B-II or common ALL Ph- (MLL negative). No central nervous system infiltration. He started induction therapy according to the PETHEMA ALL intermediate risk-2008 protocol with vincristine, daunorubicine and prednisone. BMA on day +14 without response, IF with 76% of blasts (Table 1), revealed diagnosis of more aggressive ALL: B-I or pro-B ALL Ph- (MLL negative). Due to it, he started reinduction of the PETHEMA ALL high risk-2011 protocol (Flag-IDA). Meantime an allogeneic stem cell transplant (ASCT) of unrelated donor was proposed. He presented as complications pulmonary fungal infection. On day +34 it showed lack of response, IF similar to the previous one (Table 1). A third line of treatment is proposed, starting blinatumomab after debulking with vincristine and dexamentasone. A Cytokine Release Syndrome (CRS) was reported after 3 weeks of treatment, therefore blinatumomab was delayed until CRS was controlled with conventional treatment. Reevaluation after the first cycle of blinatumomab, PB: leukocytes $2.7x10^3$/µL, neutrophils $1.5x10^3$/µL, hemoglobin 8,7g/dL, platelets $41x10^3$/µL and BMA showed morphological complete remission (CR) and minimal residual disease (MRD) + (Table 1). Finally, the patient died due to a new episode of pulmonary infection. **Case 2:** A 15 years old man, PB: leukocytes $7.8x10^3$/µL, neutrophils $1.2x10^3$/µL, hemoglobin 8.4g/dL, platelets $70x10^3$/µL, lymphoblast: 53%. BMA: 95% of lymphoblast. The IF (Table 1), cytogenetic and molecular biology analysis of the BMA confirmed the diagnosis of B-II or common ALL Ph-, t (1;19) positive. TCF3 positive and MLL negative. No central nervous system infiltration. He started treatment according to the SEHOP-PETHEMA ALL 2013 intermediate risk protocol. Early relapsed with 97% of lymphoblast in BMA. He was treated under the therapeutic recommendations for relapse SEHOP-PETHEMA ALL 2015 without response, with 33% infiltration. Rescue chemotherapy with clofarabine, cyclophosphamide and etoposide, obtaining CR with MRD: 0.01% (Table 1). As complications, febrile neutropenia with bacteremia secondary to E. coli and aspergillosis with orbital, paranasal sinus and pulmonary affectation. Due to the delay of the transplant by infections and MRD: 0.2%, blinatumomab was initiated as a bridging therapy to transplant, being well tolerated. He maintained MRD lower than 0.01% after the first cycle (Table 1). An ASCT of identical HLA brother was performed. Currently in remission and complete chimerism.
Results: The results are shown in Table 1.

Table 1.

PATIENT 1	Blasts % BM

Post SEHOP-PETHEMA 15	33	64	Similar IF
Post Clofa, Cyclo and E	-	0.01	Similar IF
Pretransplant	-	0.2	Similar IF
Post Blina 1 Cycle	-	0.01	Similar IF

Table 1. Diagnosis and re-evaluation BMA studies. Blats % BM: percentage of lymphoblasts. M: % morphology. FC: % flow cytometry. Vin: vincristine. Dex: dexamentasone. Blina: blinatumomab Clofa: clofarabine. Cyclo: cyclophosphamide. E: etoposide.

Summary/Conclusion: According to the published studies, patients with a low tumor load (<50% infiltration) obtain better results than patient with highest tumor (>90%); with CR rate of 72,9% *vs* 21,6%. In the first case, a spectacular response was observed after treatment with blinatumomab with previous debulking therapy. This strategy can be an option for patients with high tumor burden.

PB1642

OSTEONECROSIS DURING ACUTE LYMPHOBLASTIC LEUKEMIA TREATMENT

I. Yaman Bajin[1,*], S. Aytac[2], B. Kuskonmaz[2], S. Unal[2], F. Gumruk[2], M. Cetin[2]

[1]Pediatric Hematology, [2]Hacettepe University, Ankara, Turkey

Background: Avascular necrosis (AVN), also called osteonecrosis or aseptic necrosis is a condition that occurs when there is loss of blood to the bone, an interruption to the blood supply causes bone to die. Approximately 90% of the acute lymphoblastic leukemia (ALL) patients in childhood can be cured with current intensive treatment protocols. But the morbidity associated with ALL treatment become more important everyday because of the increase in the number of long-term survivors. Osteonecrosis is one of the most common therapy-related debiliating side effects of ALL treatment. Incidence and risk factors vary between study groups and therapeutic regimens. Age at diagnosis >10 years and glucocorticoid cumulative doses are known as the most significant risk factors.
Aims: We aimed to analyse the clinical features of the ALL patients diagnosed with osteonecrosis in our department.
Methods: Patients diagnosed with ALL and treated with modified St. Jude Total XV protocol in Hacettepe University, Pediatric Hematology Department between 1 January 2008 and 31 December 2015 were analysed and the patients diagnosed with osteonecrosis during ALL treatment were included the study. The clinical features that may be associated with osteonecrosis among these patients were analysed retrospectively .
Results: There were 208 patients diagnosed with ALL. Nineteen of them (9%) were diagnosed with osteonecrosis. Nine of them were girls, 10 were boys. The median age of this 19 patients at the diagnosis was 11 years (2-18y) and 15 patients were >10 years of age at the diagnosis. The immunophenotyping was found to be T cell leukemia for 6 of the patients and CALLA+ B cell ALL for the others. Four of them were low risk patients while 6 patients were standart risk and 9 were high risk patients. According to Modified St. Jude Total XV protocol 7 days of high dose methlprednisolone (HDMP) added to protocol as an initial treatment and we randomized patients at doses of 10 mg/kg/d or 20mg/kg/d HDMP: not exceeding at maximum 1000 mg methylprednisolone. After the end of 7th day of steroid concomittant chemotherapy was given and the doses were tapered gradually to 5mg/kg/d and 10mg/kg/d in each group respectively. By the 3rd week of treatment steroid dose was tapered to 2mg/kg/d in both groups and continued with this dose till the end of 3rd week of induction phase. Six patients were found to start treatment with 20mg/kg/d HDMP while 7 started with 10 mg/kg/d and the other 6 patients could not receive HDMP because they had high WBC levels at the diagnosis.
Summary/Conclusion: Osteonecrosis is one of the most important morbidities among ALL survivors. According to our study most of the patients were found to be >10 years age and mostly standart or high risk patients compatible with the literature. More studies are needed to identify the therapy-related or non-therapy-related risk factors and determine which patients are under risk to prevent this sequelae.

PB1643

SEQUENTIAL USE OF IMMUNOTHERAPY IN REFRACTORY/RELAPSED B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: CLINICAL EXPERIENCE FROM A SINGLE-CENTRE

N.S. Fracchiolla*, M. Sciumè, G. Reda, R. Cassin, A. Freyrie, M.C. Goldaniga, F.I. Grifoni, E. Tagliaferri, A. Cortelezzi

Oncohematology Division, IRCCS Ca' Granda-Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Despite the significant advances in modern chemotherapy, it remains challenging to treat adult patients with acute lymphoblastic leukemia (ALL). The relapse rate continues to be high, and the outcome at the time of relapse is dismal. In this setting of patients, antibody-based therapies have demonstrated promising single-agent activity.
Aims: We aimed to describe our clinical experience in the sequential use of the bispecific T cell engager blinatumomab and the anti-CD22 antibody-drug conjugate inotuzumab ozoagamicin (IO) in relapsed/refractory B-cell precursor ALL (R/R B-ALL).
Methods: Adult patients with R/R B-ALL initially treated with blinatumomab and then moved to IO for disease reappearance were selected from the institutional database. Clinical data, diagnostic work-up, treatment modalities, and outcomes were extracted.
Results: We identified 3 R/R B-ALL patients who received blinatumomab for a bone marrow relapse after standard chemotherapy. At blinatumomab start, median age was 58 years, male/female ratio was 2:1 and median number of prior chemotherapy lines was 3 (2–4). At diagnosis all patients had a poor-risk disease: 2 patients were Philadelphia chromosome–positive (Ph^+) ALL, while for the remaining one hyperleukocytosis was present at ALL onset and cytogenetic analysis reported 47,XXX [20]. Prior chemotherapies included Hyper-CVAD regimen and pediatric-type therapeutic program proposed by the Northern Italy Leukemia Group; both patients with Ph^+ ALL had already been treated with all available tyrosine kinase inhibitors. Blinatumomab was obtained through an expanded access use and given as continuous IV infusion at a dose of 28μg/m^2/d for 4 weeks, with a 2-week break. The median administered cycle number was 4 (2-5). For all patients complete morphological remission and cytofluorimetric negative minimal residual disease were achieved since the first cycle. Unfortunately, after a median time of 63 days 2 patients had a bone marrow relapse, one of these with CD19- lymphoblasts, while the remaining patient had an extramedullary relapse with lymph-nodes involvement. In all 3 cases blast cells showed CD22s expression by flow cytometry. Only one patient experienced a G2 neurological toxicity which progressively improved with dexamethasone. Expanded access use of IO was started for relapse after blinatumomab treatment. Patients received a combination of vincristine and prednisone to reduce the amount of ALL before IO start. Median time from blinatumomab interruption and IO was 55 days. Patients received IO IV at a dose of 1.8mg/m^2 for the first cycle and then 1.5mg/m^2, divided in three weekly doses, every 3-4 weeks for a median number of 2 cycles (1-4). Again, all 3 patients received complete morphological remission and cytofluorimetric negativity after the first cycle; for the only patient with lymph-node involvement a PET analysis demonstrated absence of active disease. IO was generally well tolerated; 2 patients had a G2 transaminases elevation. Two patients proceeded to allogeneic hematopoietic stem cell transplantation (allo-HSCT); one of this died 4 months after allo-HSCT for ALL progression, while the other one is still alive and in ALL complete remission after 2 months from allo-HSCT. One patient was not candidate to allo-HSCT and we have planned to complete 6 IO cycles.
Summary/Conclusion: This monocentric survey underlined the feasibility and efficacy of sequential use of blinatumomab and IO in R/R B-ALL with the possibility to proceed safely to allo-HSCT.

PB1644

RELAPSES OF ACUTE LYMPHOBLASTIC LEUKEMIA IN CHILDREN ON PROGRAMMED THERAPY

E. Vaskina[1,*], E. Danilova[1], I. Tataurova[1], E. Butina[2], N. Minaeva[1], V. Rosin[3]

[1]Hematology, [2]Immunohaematology, [3]Pathomorphology, Federal State Institute of Science "Kirov research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, Russian Federation

Background: Acute lymphoblastic leukemia (ALL) occupies a leading position in the structure of childhood cancer.The use of long-term multimodal therapy allowed achieving high survival rates. However, 15-20% of patients have got the relapses of the disease, which are the cause of failure of treatment of children with ALL.
Aims: To study the frequency of development of relapses of acute lymphoblastic leukemia in children on programmed therapy.
Methods: 247 patients with newly diagnosed ALL were monitored in the children's hematology department in the period from 1991 to 2017. 36 (15,4%) of children at different stages of observation have relapses. The age of patients ranged from 2 till 18 years (median 8,0 years).
Results: In the first acute period 20 (55,5%) patients were treated with protocol ALL-BFM-90; ALL-MB-2002. ALL-MB-2008. ALL-MB-2015-16 (44,4%). The structure of recurrences was as follows: isolated bone marrow relapse-27 cases, the combined-4, isolated ekstramedullar-12 (33,3%) of the relapses classified as very early, 16 (44,4%) early and 8 (22,2%) late. Antireccurence therapy was conducted in 34 patients, the two did not receive treatment due to refusal of parents. Refractory to therapy was recorded in 6 patients, 4 patients died of various complications and progression of the disease before reaching remission. The second complete remission was obtained in 70% of cases (24 patients). Transplantation of hematopoietic stem cells from an related donor carried in 1 patient, ended lethally,1 patient died of various complications during remission, 9-developed a second relapse (3 patients are alive in one-third complete remission).16 (44%) patients are in long remission.
Summary/Conclusion: The frequency of relapses in patients of ALL was 15,4%(36). 44% patients are in long remission.

PB1645

EVALUATION OF DEMOGRAPHIC, CLINICAL AND LABORATORY FINDINGS OF PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA FOLLOWED UP IN OUR CLINIC BETWEEN 2010 AND 2015

M. Solmaz[1], M. Söker[1,*], K. Yılmaz[1], H. Uzel[1], K. Öncel[1], S. Söker[2]

[1]Pediatric Hematology and Oncology, [2]Histology and Embriology, Dicle University Medical Faculty, Diyarbakır, Turkey

Background: Acute Lymphoblastic Leukemia (ALL) is the most common type of childhood cancers with a survival rate up to 80% thanks to multiple chemotherapies.
Aims: This retrospective study aims to screen patients who had been diagnosed with ALL in the Pediatric Hematology-Oncology Department of the Dicle University Faculty of Medicine between 2010 and 2015; and to reveal the mortality rate by evaluating clinical and laboratory findings, immunophenotypic and cytogenetic characteristics, morphologic features of bone marrow, and evaluating chemotherapeutic response.
Methods: The files of 121 patients who had been diagnosed with Acute Lymphoblastic Leukemia (ALL) and who had been treated with TRALL-BFM 2000 and ALL IC-BFM 2009 protocol in the Hematology and Oncology clinic of Dicle University Faculty of Medicine between 2010 and 2015 were screened retrospectively and included in the study.
Results: Of the children included in the study, 70.2% was in the 1-6 age group and 47.9% was living in the rural area. The most common symptoms during admission were fever, fatigue, pallor and loss of appetite. The most common physical examination symptom was lymphadenopathy during admission. Of the patients, 41.3% was A Rh +, 34.7% was 0 Rh + and 13.2% was B Rh +. Of the patients, 65.3% had a white blood cell count of 0-20,000/mm^3, 71.1% had a hemoglobin value of 7 g/dl and above and 67.8% had a platelet count of 100,000/mm^3 and below. t(9,22) and t (4,11) were positive in 3.3% and 0.8% of the patients, respectively. Of the patients, 78.5% was found to be pB-ALL and 21.5% was found to be T-ALL. TRALL-BFM 2000 protocol had been applied in 57% of patients, whereas ALL IC-BFM 2009 protocol had been applied in 43% of patients. The relapse rate of patients was 5.8% and the overall mortality rate was 11.6%. There was no statistically significant difference in terms of gender, white blood cell count, hemoglobin level, platelet count, immunophenotype and mortality. There was a statistically significant difference between the risk group of the patients and the protocol applied and mortality ($p<0.05$). Of those who lost their lives, 57.1% was high risk group (HRG) patients. Of the relapses, 71.4% was T-ALL. And, TRALL-BFM 2000 protocol had been applied in 85.7% of them. There was a statistically significant difference between the immunophenotype and the protocol applied and relapse ($p<0.05$).
Summary/Conclusion: Considering the age, gender, clinical findings and laboratory results, results obtained were similar to the studies in the literature. We identified the factors affecting overall survival and relapse in patients. The mortality and relapse rates were higher in the patients in the HRG. We found that ALL immunophenotype was effective on mortality and relapse rate. The relapse rate of T-ALL patients was higher than that of pB-ALL patients. In addition, the relationship between mortality and relapse and treatment protocol was investigated. We found that mortality and relapse rates were higher in the patients receiving the TRALL-BFM 2000 treatment protocol compared to the ALL IC-BFM 2009 protocol.

PB1646

USE OF BLINATUMOMAB IN MOLECULAR RELAPSE OF AN INFANT, T(4;11) POSITIVE, ACUTE LYMPHOBLASTIC LEUKEMIA

F. Petruzziello[1,*], G. Giagnuolo[1], G. Beneduce[1], G. Cazzaniga[2], G. Muccioli Casadei[3], P. Stellato[1], B. Donnarumma[1], G. Maisto[1], N. Marra[1], G. Sepe[1], C. Montagnaro[1], F. Messina[1], G. Menna[1], R. Parasole[1]

[1]Pediatric Hemato-Oncology, Santobono-Pausilipon Hospital, Naples, Italy, Naples, [2]Department of Paediatrics, Centro RicercaTettamanti University of Milano Bicocca, Fondazione MBBM, Monza, [3]Research Institute SDN- Synlab Group, Naples, Italy

Background: At present, there is no consensus about how to treat infant with molecular relapse of Acute Lymphoblastic Leukemia (ALL) and t(4;11). "*Watch and wait*" strategy is the actual approach until evidence of hematological relapse for which there is no specific validate treatment.
Aims: We describe the case of a 2-year- and 6-month-old boy, with previous diagnosis (March 2016) of infant pro-B ALL, t(4;11) positive, treated according to the AIEOP INTERFANT 2006 Protocol. The patient resulted good prednisone responder on day +8. Minimal residual disease (MRD) was positive both on day +33 and +78. At the end of Induction, the MLL/AF4 rearrangement was negative. After Consolidation (MARMA cycle), MRD was still positive (Marker 1:<1x10^{-4}; Marker 2:<1x10^{-4}). According to protocol, the patient was not eligible for allogenic hematopoietic stem cell transplantation (HSCT) so, he continued therapy with Reiduction (OCTADAD); at the end of this cycle, MRD was still positive. On October 2016, the patient started Manteinance and MRD, at the first four controls resulted negative. On October 2017, it turned positive and MLL/AF4 rearrangement was again detected with negativity of Central nervous system (CNS). According to protocol, we had to monitor the disease course until a possible relapse. However, the new MRD positivity was pathognomonic of oncoming hematological relapse. The efficacy of Blinatumomab in MRD treatment of adult and pediatric ALL is well established. To avoid child's hematological relapse, at very poor prognosis, and to ensure a treatment option that allow the successful of allogenic HSCT, compassionate use of Blinatumomab was purposed.
Methods: In December 2017, written informed consent was obtained and Blinatumomab was started at the dose of 5mcg/m^2 daily for the first 7days of cycle 1. Then, the dose was increased to 15mcg/m^2 daily. To prevent neurological toxicity, prophylaxis with Levetiracetam was started. Two 28-days cycles of Blinatumomb were performed from December 2017 to February 2018. CNS prophylaxis was performed with 2 intrathecal administration of Methotrexate and Prednisone.
Results: MRD was already negative after 15 days of treatment, and remained negative until the end of the first cycle; at the same time, MLL/AF4 rearrangement resulted absent from day +15. The analysis of MRD and MLL/AF4 rearrangement persisted negative after the second cycle. The patient tolerated well the therapy, enjoying a good quality of life; the only side effect was fever during the first day of drug infusion. At the last clinical check, the child was in good general condition and shows no signs and/or symptoms of disease and he is waiting for allogenic HSCT.
Summary/Conclusion: In this case, the use of Blinatumomab alone allowed the patient to achieve complete molecular response. It is important to underline that, the child fastly obtained complete molecular remission with the use of immunotherapy without using chemotherapy. The use of Blinatumomab resulted active and well tolerated so, it was an excellent bridge to transplant. Blinatumomab in a molecular relapse of infant ALL could be an effective alternative to the current "*watch and wait*" strategy, whereas there is not specific validate treatment in case of hematological relapse.

PB1647

ACUTE LYMPHOBLASTIC LEUKEMIA IN PREGNANCY: A CASE REPORT

A. Zhumagaliyeva[1,*], D. Nurgaliyeva[2], L. Karazhanova[1]

[1]Internal Medicine, Semey State Medical University, [2]Hematology, Emergency hospital of Semey, Semey, Kazakhstan

Background: The frequency of cancer and pregnancy is relatively rare, occurring in about one in 1000 pregnancies. The most common tumors diagnosed during pregnancy are cervical and breast cancer followed by melanoma, leukemia and lymphoma. The conducting of a pregnant patient with malignancy is very challenging and requires a multidisciplinary approach.
Aims: Here, we present a case of acute lymphoblastic leukemia in pregnancy.
Methods: A 29-year-old female at 28 weeks gestation presented to the emergency department with a 7-day history of fatigue, fever, bruising along with nose and gum bleeding. Laboratory investigation revealed a white blood cell count of 77.3x10^3/mm^3, hemoglobin 3.8 (g/dl) and platelets 10x10^3/µl.
Results: A bone marrow biopsy revealed precursor B-cell ALL, 93% blasts with BCR-ABL rearrangement (Philadelphia chromosome) by fluorescent *in situ* hybridization (FISH) in 81% of cells and reverse transcriptase-polymerase chain reaction (RT-PCR) detecting BCR-ABL breakpoint fusion. Cytogenetics showed 46,XX,t(9;22)(q34;q11.2) and immunohistochemistry revealed the following: moderately positive for CD10, CD19, CD22, CD34, CD45, HLA-DR and cytoplasmic Tdt while negative for CD3, CD5, CD11b, CD15, CD20, CD33, CD38, CD56, CD71, CD117, kappa and lambda light chain surface antigen. Ultrasound revealed a single living fetus at 28 weeks with weight corresponding to the 39th percentile and normal amniotic fluid. The solution was made to wait until 30 weeks to deliver the baby via Caesarean section due to an operative risk of hemorrhage and sepsis to the mother if delivered while pancytopenic and to give more time for fetal maturity. The patient was started on intravenous HyperCVAD without any dose reduction. At 30 weeks gestation (2 weeks after initiation of induction therapy), a Caesarean section was performed with the delivery of a baby girl with a weight of 1346 grams corresponding to the 26th to 50th percentile for the gestational age. The baby required transient respiratory

assistance for 10 hours post delivery due to cyanosis and poor respiratory effort. On postpartum day 11 the mother was started on HyperCVAD combination chemotherapy and dasatinib at 50 mg twice a day for 14 days given with each cycle of chemotherapy. She was also given prophylactic intrathecal chemotherapy. Cerebrospinal fluid analysis done after delivery was negative for central nervous system implication. A bone marrow biopsy accomplished after completion of cycle one of high-dose cytarabine and methotrexate revealed normal cytogenetic. BCR-ABL was negative by FISH and PCR detected 0.005% residual BCR-ABL. No blasts in bone marrow biopsy were found and flow cytometry was negative. Currently she is awaiting allogenic bone marrow transplant. The baby continues to do well and has reached normal developmental milestones at 18 months of age.
Summary/Conclusion: Our case represents the feasibility of treating ALL with HyperCVAD during the third trimester of pregnancy with favorable outcomes.

PB1648

PRECURSOR B AND T CELL MALIGNANCIES IN ADOLESCENTS AND YOUNG ADULTS IN QATAR;EPIDEMIOLOGY AND CLINICAL FEATURES

R.Y. Taha*, A.Y. Ellahie, H. El Omri, O.M. Ismail, G. Pittari, H. Elsabah, I. Al Hijji

Hematology-BMT, Hamad Medical Corporation, Doha, Qatar

Background: Precursor B and T cell lymphoid malignancies represent heterogeneous disorders in terms of natural course and outcome especially when comparing pediatric and adult populations, such variation reflects the different biology between these age subtypes. The definition of adolescents and young adults (AYA) is itself controversial and varies in trials .It can be up to age of 40 or even 50. AYA patients with acute lymphoblastic leukemia (ALL) have outcomes that are historically inferior to those of children largely due to the increase frequency of adverse genetic alterations in adults; like the higher frequency of Philadelphia chromosome-positive or the recently described Philadelphia like ALL.
Aims: To report the clinical and prognestic factors of AYA patients diagnosed with precursor lymphoid malignancy in Qatar and establish the age cutoff at which adverse clinical and biological findings are observed.
Methods: This is a retrospective study in the National Centre for Cancer Care and Research which is the only cancer care provider for adults in Qatar. Patients diagnosed with B or T cell ALL or lymphoblastic lymphoma older than or equal 14 year old and who were diagnosed between January 2013 and December 2017 were included. We defined AYA as patients diagnosed at 39 year of age or younger (14-39 year old). we studied the occurence of adverse clinical and cytogenetic variables and compared them in AYA and non AYA groups. White blood cell count (WBC) cutoff at diagnosis of $>100x10^3$/mcl for T cell malignancy and $>30x10^3$/mcl for B cell subtype were considered adverse.
Results: A total of 83 patient were identified,74 males and 9 females (the significant gender variability is due to Qatar demographics were male industrial task force constitute most of the population). Median age at diagnosis was 30 (range15-71). 61 patients were in the AYA group (88% of the cohort) and 22 patients were non AYA. B cell lymphoblastic lineage contributed to 51% of ALL diagnosis in the AYA group and 48% were T cell malignancy. AYA patients with T cell lineage ALL had higher WBC at diagnosis when compared to non AYA (P=0.034).No significant difference in WBC between both groups in B cell subtype. Moreover,AYA patients had significantly lower frequency of (Ph+) ALL than non AYA.(P=0.004), other cytogenetic abnormalities were similar in both groups.
Summary/Conclusion: Our cohort identified 39 year of age as the cutoff at which prognosis differs. There was lack of favorable cytogenetics in all the cohort and predominence of (Ph+) ALL in patients 40 year old or older. Moreover AYA patients with T lymphoblastic malignancy presented with more bulky disease and higher risk features.

Background: Aspergillus flavus is a rare but increasingly common mold fungus. Especially in hematologic malignancies, it is seen as a factor in the neutropenic period when the immunity system is suppressed; and mortality is high in these patients.
Aims: We aimed to present a case of by Aspergillus flavus osteomyelitis with in an adolescent with acute lymphoblastic leukemia (ALL).
Methods: A 14-year-old male patient with ALL was hospitalized with neutropenia on the 30th day of treatment. On the 12th day of neutropenia, treatment with amikacin, meropenem and liposomal amphotericin B was initiated. In this period, the patient developed swelling of the left knee joint. Magnetic resonance imaging (MRI) showed that may be compatible with abscess and osteomyelitis in left femur distal metaphyseal. The patient was operated and intraarticulary washing was performed, the soft tissue / bone curettage materials were sent to pathology and microbiology laboratories. Pathology was again reported as fungal osteomyelitis. Aspergillus flavus was grew from the tissue samplesThe minimum inhibitor concentration (MIC) values for amphotericin B, caspofungin, voriconazole, anidulafungin, itraconazole and posaconazole were >2μg/ml, 0.125μg/ml, 0.064μg/ml, 0.002μg/ml, 0.25μg/ml, and 0.125μg/ml. Amphotericin B in the patient was discontinued and voriconazole was started because the A. flavus strain was resistant to amphothericin B. Progression was seen in the patient's knee MRI with complaints after the second week of voriconazole treatment. For the third time, the patient was treated with curettage and washing with voriconazole. Aspergillus-compatible fungi were seen in specimens taken prior to washing with voriconazole and sent to the mycology laboratory. Although galactomannan antigenemia tests in blood samples were negative during neutropenia, galactomannan antigenemia test was positive in the last joint fluid and tissue sample. However, there was no reproduction in culture. Caspofungin was added to the patient's treatment.
Results: Fungal infections and especially osteomyelitis related to Aspergillus species should be considered in children with ALL and neutropenia.
Summary/Conclusion: It should be kept in mind that A.flavus, which is seen more rarely, may also be resistant to the agent and amphotericin B as a Nosocomial fungal infecion

PB1650

VENA CAVA SUPERIOR SYNDROME IN CHILDREN WITH MEDIASTINAL TUMORS: SINGLE CENTER EXPERIENCE

T. Patiroglu[1,*], A. Ozcan[2], E. Unal[1], M. Karakukcu[1], A. Coskun[3]

[1]Pediatric Hematology, [2]Erciyes University Medical Faculty, [3]Pediatric Radiology, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Vena cava superior syndrome (VCSS) comprises various symptoms of compression of vena cava superior. The resulting increased venous pressure in the upper body may cause edema of the head and neck associated with cyanosis, pletore and distended subcutaneous vessels.
Aims: VCSS is rare in childhood. Therefore, we planned this retrospective study.
Methods: The retrospective study was carried out on the children with mediastinal tumors in the department of pediatric hematology-oncology, Erciyes University Medical School, from january 2010 to december 2017. Diagnostic procedures included hematological investigations, chest radiography, thoracic computed tomography, echocardiography and lymph node or mediastinal biopsy.
Results: 19 (five were female) of 41 patients with mediastinal tumors had VCSS. Mean age of the patients with VCSS was 8.57 years (range:1-17 years). Diagnosis included Hodgkin's disease (HD) in 7,non-Hodgkin's lymphoma (NHL) in 6, acute T- lymphoblastic leukemia in 5, neuroblastoma and anaplastic round cell sarcoma in one each respectively. All the 19 patients had dyspnea, venous distention and mediastinal widening. Two patients with NHL had bilateral pleural effusion. All patients received intravenous corticosteroids (0.6 mg/kg dexamethasone). Furthermore, the patient with anaplastic round cell sarcoma recevied emergency radiotherapy. All patients received chemothepy and followed up in our PHO clinic. No patients died because of VCSS.
Summary/Conclusion: Compression of structures in the superior mediastinum is known as VCSS that it is a medical emergency requiring urgent treatment. In this retrospective study, we found that the most common cause of VCSS was HD as different from literature.

PB1651

BLASTS WITH ABUNDANT CYTOPLASMIC GRANULES: A CASE REPORT OF REFRACTORY GRANULAR ACUTE LYMPHOBLASTIC LEUKEMIA WITH HETEROZYGOUS DELETION OF IKZF1

L. Peng*, L. Ye, Y. Jiang

Department of Laboratory Medicine, West China Second University Hospital, Sichuan University, Chengdu, China

Background: The finding of cytoplasmic granules in blasts is one of main morpholoic features to distinguish AML from ALL. Rarely, significant and thick granules may be presented in cytoplasm of blasts in ALL, known as granular acute lymphoblastic leukemia, indicating a worse prognosis. IKZF1 deletion is an independent prognostic marker in childhood B-cell precursor acute lymphoblastic leukemia.
Aims: Morphology and cytochemical evaluation of peripheral blood or bone marrow aspirate smears are still main examinations to diagnose hematological diseases. To reduce the misdiagnosis and improve the prognosis of granular ALL, it is neccsary to understand its features differed to AML and classic ALL.
Methods: Morphology, flow cytometry, leukemia related fusion genes screen and karyotype analysis were applied in this 12-year-old boy whose white blood cell of peripheral blood rise obviously. csary to understand its features differed to AML and classic ALL.
Results: The peripheral blood and bone marrow blasts showed abundant of cytoplasmic granules(panel a and b; original magnification *1000, Wright-Giemsa stained) and were positive for CD10, CD19, CD20, CD34, HLA-DR, cCD79a, terminal deoxynucleotidyltransferase and CD22(partial). The heavily granulated lymphoblasts in the blastic population of bone marrow aspirate was 53.0%. These blasts were positive for Periodic Acid-Schiff reaction(panel c) but completely negative for myeloperoxidase(panel d) by cytochemical staining. His FAB subtype of morphology was L2. More than 30 leukemia fusion genes were screened and the results were negative. A heterozygous deletion of Exon 4-8 in IKZF1 gene was found. Cytogenetic analysis brought normal karyotype 46 XY. His prognosis was poor with VDLP chemotherapy (vincristine sulfate, daunorubicin, pamnidase, prednisone acetate, dexamethasone) induced chemotherapy was given successively.

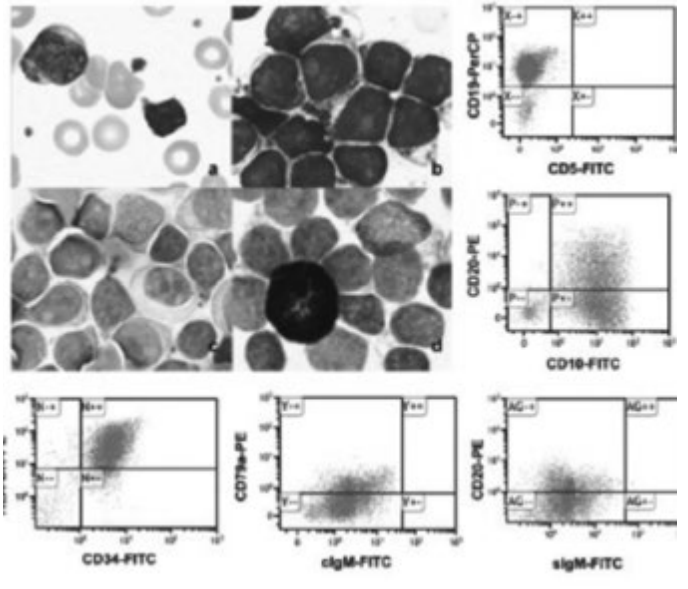

Figure 1.

Summary/Conclusion: Granular ALL is a rare morphologic subtype of ALL which was reported in just over 100 cases. Those large cytoplasmic granules closely mimicked heavily granulated myeloblasts in acute myeloid leukemia. The granules of granular ALL are thought to be the result of dysplastic organella formation, fusion, or degeneration, such as multivesicular bodies or Gall Bodies. Granular ALL may not only cause problematic distinction from myeloid differntiation but also associated with a worse prognosis when compared to other ALL patients. This patient was in a high risk of bad prognosis for granular ALL subtype and heterozygous deletion of IKZF1. We should keep in mind since this ALL subtype may easily be mistaken for acute myeloid leukemia during morphologic evaluation. This potentiality further emphasizes the importance of molecular diagnosis and immunophenotype in the characterization of leukemias.

PB1652

INTRAVENOUS IMMUNOGLOBULIN REPLACEMENT THERAPY IN ACUTE LEUKEMIA PATIENTS

A. Bahadır[1,*], E. Erduran[2], F. Orhan[3]

[1]Divison in Pediatric Hematology-Oncology, [2]Division in Pediatric Hematology-Oncology, [3]Division in Pediatric Allergy-Immunology, Karadeniz Technical Univercity, Trabzon, Turkey

Background: Intravenous Immunoglobulin (IVIG) is widely used in primary immune syndrome cases due to the high risk of infection associated with hypogammaglobulinemia. For the last two decades, immunoglobulin replacement therapy has been used to treat lymphoproliferative diseases which cause secondary antibody deficiency, and also to treat hematological diseases, such as multiple myeloma. In malignancies, iatrogenic hypogammaglobulinemia is associated with chemo-immunotherapy regimens (anti-CD20 therapy), immunosuppressive therapies (steroid, mycophenolate mofetil) and chemotherapeutic agents (cyclophosphamide, fludarabine), and in such patients, serious infection attacks may occur that are associated with the dysregulation of the immune system and hypogammaglobulinemia.
Aims: This study involves the initiation of IVIG prophylaxis in pediatric patients diagnosed with acute lymphoblastic leukemia (ALL) who were treated and followed-up by our team, who had frequent and life-threatening infections and who had decreased immunoglobulin levels when compared to their pre-treatment levels. This report contains the results of our preliminary study.
Methods: Pediatric hematology-oncology patients diagnosed with ALL between 2010 and 2017, presenting with no immunodeficiency at the time of diagnosis and receiving treatment based on the St. Jude Total XV chemotherapy protocol were enlisted in this study. Repetitive infection attacks, multiple neutropenic infection incidences per month, chemotherapy interruptions of longer than one month, age-adjusted drops in immunoglobulin levels below -2SD or by more than half of the immunoglobulin levels at the time of diagnosis were accepted as IVIG prophylaxis initiation criteria. Regular IVIG prophylaxis of 0.5 gr/kg at three-week intervals was initiated for these patients.
Results: Of the five patients, who were enrolled in the program, three were male and two were female. The patients were followed up with a high-risk ALL diagnosis, and that the findings showed that one patient had T-cell ALL and the others had B-cell ALL. The age range of patients was 10 months to six years. It was observed that incidences of neutropenic infection in patients that require hospitalization following prophylaxis decreased, and their treatment continued without interruption.
Summary/Conclusion: After IVIG prophylaxis, incidences of neutropenic infection in our patients were seen to decrease, and as a result of this decrease, our patients were provided with regular and continuous treatment. There are very few studies in the literature that involved IVIG prophylaxis in pediatric leukemia patients with secondary hypogammaglobulinemia. Being a preliminary study at its current stage, the collection of data related to this study is continuing.

PB1653

HEPATITIS C VIRUS INFECTION-ASSOCIATED MACROPHAGE ACTIVATION SYNDROME IN A PEDIATRIC PATIENT WHICH UNDERWENT HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE LYMPHOBLASTIC LEUKEMIA

G. Laccetta[1], M. Menconi[1,*], S. Bernasconi[1], G. Casazza[1], M. Brunetto[2]

[1]Pediatric Department, [2]Hepatology department, Azienda Ospedaliera Universitaria Pisana, Pisa, Italy

Background: Hepatitis C virus (HCV) infection causing Macrophage Activation Syndrome (MAS) in pediatric population has never been reported previously.
Aims: To describe a case of MAS associated with HCV infection in a pediatric patient.
Methods: We describe a case of MAS associated with HCV infection in a girl with acute lymphoblastic leukemia (ALL) which underwent hematopoietic stem cell transplantation (HSCT) and attained viral suppression with ledipasvir/sofosbuvir.
Results: A 13-year-old Ukranian girl with pro-B cell ALL t(4;11)(q21-q23), and HCV-genotype 1 infection (HCV-RNA 629.500 IU/mL) received chemotherapy according to the AIEOP ALL 2000 protocol and a myeloablative allogeneic HSCT from MUD; the engraftment was at day +19 after HSCT (neutrophils 580/μL). At day +22 the patient presented epigastric pain, icteric skin, fever (39°C), vomiting and diarrhea. Blood exams showed

progressive cytopenia (WBC 670/µL, N 120/µL, Hb 9.0 g/dL, PLT 22.000/µL), hypofibrinogenemia (fibrinogen 100 mg/dL), ALT 283U/L, AST 323U/L, hyperbilirubinemia (total bilirubin 11.0 mg/dL, direct bilirubin 10.4 mg/dL), hypertrigliceridemia (tryglicerides 460mg/dL), hyperferritinemia (ferritin 67.769 ng/mL). Blood culture was negative; CMV, EBV Adenovirus-PCR were negative; serology for hepatitis A and HBV-DNA were negative but HCV-RNA was >100.000.000 IU/mL. Clinical examination and abdominal ultrasound revealed hepatosplenomegaly and BOM showed CR for ALL but increased histiocytes and macrophages with hemophagocytosis; no signs of GvHD. MAS secondary to HCV infection was suspected and treatment with high-dose corticosteroids, cyclosporine-A and ledipasvir/sofosbuvir was initiated. At day +38 after HSCT fever disappeared, laboratory exams improved and quantitative PCR for HCV-RNA decreased (19.114.275 IU/mL); after 4 weeks of antiviral treatment HCV-RNA was negative. At day +82 the patient presented fever (39.1°C), headache, left facial droop, right convergent strabismus, aphasia, disequilibrium, gait unsteadiness, absence of deep tendon reflexes, clumsiness of both hands and drowsiness. Brain-MRI showed multiple supra and infratentorial areas of mass-like appearance with central necrosis surrounded by a hyperintense ring; a broad laboratory workup confirmed cerebral reactivation of MAS. Thus, the dose of intravenous corticosteroids was increased and intravenous mannitol was administered to reduce intracranial pressure; phenobarbital and carbamazepine were initiated. The antiviral therapy with ledipasvir/sofosbuvir was discontinued at day +200 (for a total of 6 months). At follow-up, ten months after HSCT the girl developed chronic kidney failure. Twelve months after HSCT the patient is alert, fully oriented, with fluent speech and normal language; she has a permanent left facial droop, a diffuse left lower extremity weakness, reduced deep tendon reflexes and steppage gait on her left. Brain-MRI shows neither new lesions nor an enlargement of the previously described areas; the last quantitative PCR for HCV-RNA is negative and BOM aspirate shows CR for ALL and MAS with full donor chimerism.

Summary/Conclusion: In our case MAS was probably triggered by HCV and the early treatment with ledipasvir/sofosbuvir revealed to be highly effective for HCV infection and well tolerated by the patient; despite viral clearance, HLH persisted over time with permanent neurologic impairment and chronic kidney failure.

A QUARTER OF NRAS POSITIVE PATIENTS CARRY MULTIPLE POINT MUTATIONS, EACH OF THEM LOCALISED SEPARATELY IN DIFFERENT ALLELES

A. Durinikova[1,2,*], I. Jeziskova[2], A. Folta[2], D. Al Tukmachi[1], Z. Kosarova[1], M. Culen[1,2], D. Dvorakova[1,2], N. Tom[1], P. Cetkovsky[3], P. Jindra[4], T. Szotkowski[5], P. Zak[6], J. Mayer[1,2], Z. Racil[1,2]

[1]Masaryk university, [2]University hospital Brno, Brno, Czech republic, Brno, [3]Institute of Hematology and Blood Transfusion, Prague, [4]University Hospital Pilsen, Pilsen, [5]University Hospital Olomouc, Olomouc, [6]University Hospital Hradec Kralove, Hradec Kralove, Czech Republic

Background: With frequency of 11-30% the *NRAS* mutations represent one of the most frequently reported mutations in patients with *de novo* acute myeloid leukemia (AML). Point mutations of the gene are heterozygous and exclusively affect glycine hotspot codons 12, 13 (exon 2) and 61 (exon 3). In some AML patients more than one *NRAS* mutation can be identified. The exact number of patients with multiple point mutations is unclear as well as it is not known whether the multiple point mutations are localised on the same allele of one clone or are carried by separate clones.
Aims: To describe the frequency and type of *NRAS* mutations and to analyse the polyclonality of mutations in selected patients.
Methods: NGS libraries were prepared from peripheral blood samples from the time of diagnosis of 258 consecutive *de novo* AML patients (median age 54 years; range 19-72) by ClearSeq AML panel (Agilent Technologies) and sequenced on NextSeq machines (Illumina). *NRAS* positive samples with a variant allele frequency (VAF) ≥1% according to NGS were verified by *NRAS* StripAssay (ViennaLab). The clonal background of multiple point *NRAS* mutations was analysed using TA Cloning Kit (Thermo Fisher Scientific). Sanger sequencing was used to analyse bacterial clones.
Results: In the studied cohort of AML patients the presence of *NRAS* mutation was identified in 58/258 (22.5%) patients analysed by NGS method. *NRAS* positivity was confirmed in all samples (58/58, 100%) by hybridization strips. One mutation was detected in 42/58 patients (72.4%), in remaining 16/58 (27.6%) patients multiple point mutations were revealed. Two point mutations were detected in 12/58 (20.7%), 3 mutations in 3/58 (5.2%) and 4 mutations in 1/58 (1.7%) patients. In total, 13 different gene aberrations were identified. The most frequent mutations were G12D (23/58 patients; 39.7%), G12S (14/58; 24.1%) and G13D (12/58; 20.7%). The polyclonality of *NRAS* mutations was analysed in two patients. First patient carried three mutations (G12D, G12S, G13D) in two different codons, second patient carried two mutations (G13D, Q61H) in two different exons. Analysis of 111 bacterial clones of the first patient and 112 clones of the second patient did not reveal any double-locus mutants with two mutations in the same allele. Each of the identified mutations was separate in different alleles indicating the presence of more clones.
Summary/Conclusion: More than one fifth of AML patients carry somatic missense mutation in *NRAS* gene and approximately a quarter of them has multiple point mutations. Our results show that each of the multiple point mutations is present separately in the allele and thus likely forms independent clone.

PB1655

ANTITUMOR ACTIVITY OF BIBR1532, A SELECTIVE SMALL MOLECULE INHIBITOR OF TELOMERASE, IRRESPECTIVE OF P53 STATUS OF TUMOR CELLS

A. Pourbagheri-Sigaroodi[1,*], D. Bashash[2], S.H. Ghaffari[3]

[1]Department of Biotechnology, faculty of Advanced Sciences and Technology, Pharmaceutical sciences branch, Islamic Azad University (IAUPS), [2]Department of Hematology and Blood banking, School of Allied Medicine sciences, Shahid Beheshti University of Medical Sciences, [3]Hematology, Oncology and Stem Cell Transplantation Research Center, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: The interweaving between telomerase and immortalization of tumor cells steered treatment strategies into an endless path of targeted therapies. For the nonce and among the overabundance of promising inhibitors, exploitation of potent molecules targeting telomerase turns to be intensively encouraging.

Aims: To assess the anti-tumor effect of telomerase inhibition in cancer, a panel of human tumor cells spanning from solid tumors to hematologic malignancies was treated with the different concentrations of small molecule inhibitor of hTERT, BIBR1532.
Methods: MTT, Trypan blue, annexin/PI staining, cell cycle analysis, caspase-3 activity, and cell-based NF-κB phosphorylation assays coupled with analysis of gene expression by using quantitative real-time PCR were applied to examine the effects and molecular mechanisms of action of BIBR1532.
Results: We found that BIBR1532 exerted a potent cytotoxic effect on all the tested human cancer cells; however, as compared with leukemic cells, solid tumor cells were more resistant to the inhibitor. By investigating the relative sensitivity of leukemic cells to BIBR1532, we failed to identify any relationship between p53 status and cell response to the inhibitor. Our results also indicated that telomerase inhibition using BIBR1532 resulted in a considerable growth suppressive effect in APL-derived NB4 cells, as the most sensitive cell line, mostly through p21-mediated G1 arrest coupled with a caspase-3-dependent apoptosis via suppression of NF-κB. Moreover, the resulting data showed that combination of BIBR1532 and ATRA produced synergistic anticancer effects in mutant p53-expressing NB4 cells.
Summary/Conclusion: Our study not only indicated the potential application of BIBR1532 in both wild-type and deficient p53-expressing cells but also outlined the therapeutic efficacy of the inhibitor as either single agent or in combination with ATRA in APL.

PB1656

INHIBITION OF DNA METHYLTRANSFERASES BY VOLASERTIB IN HMA RESISTANT CELL LINES

S.-H. Ko*, E.-H. Hur, B.-K. Goo, J. Moon, E.-J. Choi, H.-S. Park, K.-H. Lee, J.-H. Lee, J.-H. Lee

Department of Hematology, Asan Medical Center, Seoul, Korea, Republic Of

Background: Resistance to hypomethylating agents (HMA) in myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) is a concerning problem. We established HMA resistant cell lines with overexpression of DNA methyltransferases (DNMTs), which were not suppressed by azacitidine or decitabine. Polo-like kinase 1 (PLK1) is a key cell cycle modulator and is associated with regulation of the PIK3/Akt pathway, which was reported to stabilize DNMTs.
Aims: We evaluated whether volasertib, a PLK inhibitor, might overcome HMA resistance through regulation of PIK3/Akt pathway and DNMTs.
Methods: Cell viability was determined in HMA resistant cell lines (MOLM/AZA-1 and MOLM/DEC-5) and MOLM-13. Specific antibodies including phosphorylated-histone H3 (PHH3), caspase 3, PARP, and XIAP were used to evaluate apoptosis or DNA damage. We also analyzed phosphorylated-Akt (p-Akt), Akt, and DNMTs (DNMT1, 3A, and 3B) by immunoblot assay.
Results: Volasertib effectively inhibit proliferation of MOLM/AZA-1 and MOLM/DEC-5 cells as well as MOLM-13 cells in a dose dependent manner. It also showed superior anti-leukemic effects compared to cytarabine, azicitidine or decitiabine. Volasertib showed a dose dependent increased expression of PHH3, caspase 3, and PARP, and decrease of XIAP. Treatment of volasertib caused decreased expression of p-AKT and all DNMTs (DNMT1, 3A, and 3B). GDC-0941, a PI3K inhibitor, suppressed DNMT1 and DNMT3A as well as p-Akt, but it could not decrease DNMT3B. A combination of volasertib and decitabine showed synergistic effects in MOLM/DEC-5. Anti-proliferative effects of volasertib were sustained in *ex vivo* AML or MDS samples.
Summary/Conclusion: In our HMA resistant models, volasertib effectively inhibited all DNMTs. DNMT1 and 3A seemed to be suppressed via regulation of PI3K/Akt, but suppression of DNMT3B by volasertib might have separate mechanisms. Our data suggest that volasertib with or without decitabine has potential role in overcoming the HMA resistance in patients with AML and MDS.

CD44-HYALURONAN INTERACTION INDUCES VLA-4 CLUSTER FORMATION LEADING TO ENHANCED ADHESION OF AML CELLS ON VCAM-1

J.C. Gutjahr[1,2,*], E. Bayer[1,2], X. Yu[3], J.M. Laufer[4], A. Chigaev[5], D.F. Legler[4], R. Greil[1,2], L. Pleyer[1,2], V. Orian-Rousseau[3], T.N. Hartmann[1,2]

[1]Third Medical Department with Hematology, Medical Oncology, Hemostaseology, Infectious Diseases, and Rheumatology, Oncologic Center, Paracelsus Medical University, [2]Cancer Cluster Salzburg, Salzburg Cancer Research Institute-Laboratory for Immunological and Molecular Cancer Research, Salzburg, Austria, [3]Karlsruhe Institute of Technology, Institute of Toxicology and Genetics, Karlsruhe, Germany, [4]Biotechnology Institute Thurgau, University of Konstanz, Kreuzlingen, Switzerland, [5]Department of Pathology and Cancer Center, University of New Mexico, Albuquerque, NM, United States

Background: The bone marrow niche is critical for maintenance and retention of normal and malignant stem and progenitor cells. Key factors of this process are the adhesion molecule CD44 and the integrin VLA-4, a CD49d/CD29 heterodimer. CD44 comprises a glycoprotein family, which is tightly regulated by alternative splicing of up to 10 exons, thereby influencing the binding capacity of the ligands, particularly hyaluronan. In AML, CD44 has early been suggested as a marker for poor prognosis and leukemia initiating cells but how CD44 standard and variant forms interact with other adhesion molecules and shape the tumor environment is still not understood well.
Aims: Here we aimed to identify the functional interplay between the homing receptors CD44 and VLA-4 in AML primary patient samples as well as AML cell lines and elucidate the influence of therapeutic kinase inhibitors on the signaling cascades involved in the CD44/VLA-4 interaction, which may influence drug resistance and AML engraftment.
Methods: We employed flow cytometry for surface phenotyping of CD44, CD44v6, and CD49d on primary patient samples, and several AML cell lines. Composition of all CD44 variants was further screened by reverse transcription-PCR. Hyaluronan binding capacity was determined by flow cytometric assays and videomicroscopic adhesion assays under shear flow. VLA-4 binding capacity was determined in adhesion assays under shear flow on VCAM-1 substrates. VLA-4 activation was further studied by cytometrical assays determining integrin affinity in real-time and integrin clustering was analyzed by immunofluorescence and quantified using a confocal microscope. Signaling cascades were approached by using a range of src kinase, CD45, PI3K and other kinase inhibitors, among them midostaurin. Short-term adoptive transfer experiments of AML cells in immunodeficient donor mice were used to investigate the individual as well as synergistic role of CD44 and VLA-4.
Results: We demonstrate that CD44, CD44v6 and CD49d are expressed on primary AML cells and on AML cell lines OCI-AML3 and KG-1a at comparable amounts. Hyaluronan binding of AML cells was constitutive, suggesting an activated phenotype, dependent on functional CD44, which correlates with CD44v6 expression. Stimulation of CD44 via hyaluronan induced VLA-4 activation in a specific manner involving CD45, Src kinases, PI3-kinase, and could also be inhibited by midostaurin. CD44-induced inside-out activation of VLA-4 resulted in enhanced adhesion of AML cells on VCAM-1, which was mechanistically based on integrin clustering but not affinity regulation. Pathophysiological consequences are currently investigated using murine models engrafted with primary AML samples.
Summary/Conclusion: Based on our findings we propose that CD44-hyaluronan binding interactions promote clustering of VLA-4, which increases its adhesiveness to VCAM-1, resulting in supportive bone marrow lodgment of leukemia cells. Collectively, our investigations provide a mechanistical description of a novel CD44 function in acute myeloid leukemia, *i.e.* activation of VLA-4, required for leukemia cell recirculation and engraftment in the bone marrow environment.

PB1658

HISTONE DEACETYLASE 1 INDUCED BY NEDDYLATION INHIBITION CONTRIBUTES TO DRUG RESISTANCE IN ACUTE MYELOGENOUS LEUKEMIA

L. Wang[1,*], X.-W. Bi[2], Y.-Z. He[1], Q.-Y. Lai[1], J.-H. Wang[3]

[1]Hematology, ZhuJiang Hospital, Southern Medical University, [2]Sun Yat-sen University Cancer Center, [3]Hematology, GuangDong General Hospital, Guangzhou, China

Background: Neddylation, mediated by an ubiquitin-like molecule, Nedd8 (neural precursor cell expressed developmentally down-regulated 8), plays an important role in the regulation of protein function turnover. The role of neddylation of histone deacetylase 1 (HDAC1) in drug resistance of acute myelogenous leukemia (AML) cells remains unclear.
Aims: This study aimed to investigate the function and mechanism of neddylation of HDAC1 underlying drug resistance of AML cells.
Methods: The expression of HDACs (HDAC1–11) in five cases of refractory AML was compared to that of five cases of remission AML. In the attempt of identify the main role of HDAC1 in the drug resistance of AML, the nondrug-resistant AML cell lines (HL-60 and K562) and primary BMCs of remission AML patients were transfected with pcDNA-HDAC1 to stably express HDAC1. The effects of HDAC1 on the ADM resistance of AML

cells were assessed by the cell viability, apoptosis and ADM-releasing index. Next, we knocked down HDAC1 via the specific RNAi sequence for HDAC1 in HL-60/ADM, K562/A02, and primary BMCs of refractory AML patients and examined the effect of HDAC1 silencing on ADM resistance. To detect the potential mechanism underlying the higher level of HDAC1 in drug-resistant AML cells, we first compared the differential expression of HDAC1 in nondrug-resistant AML cells and drug-resistant AML cells incubated with cyclohexane (CHX), a protein synthesis inhibitor. We next sought to determine the mechanism in the degradation inhibition of HDAC1 protein in drug-resistant AML cells. Finally, an AML cell xenograft mouse model was established and used to evaluate the effect of HDAC1 on the tumor growth in the presence of ADM and Farydak treatment.
Results: The results showed that HDAC1 was significantly upregulated in refractory AML patients, as well as in drug-resistant AML cells (HL-60/ADM and K562/A02). Intracellular HDAC1 expression promoted adriamycin (ADM) resistance of HL-60, K562, and primary bone marrow cells (BMCs) of remission AML patients as shown by increasing cell viability and ADM-releasing index, inhibiting cell apoptosis. Moreover, HDAC1 protein level in AML cells was regulated by the Nedd8-mediated neddylation and ubiquitination, which further promoted HDAC1 degradation. In vivo, HDAC1 overexpression significantly increased ADM resistance; while HDACs inhibitor Farydak markedly improved the inhibitory effect of ADM on tumor growth. Furthermore, HDAC1 silencing by Farydak and/or lentivirus mediated RNA interference against HDAC1 effectively reduced ADM resistance, resulting in the inhibition of tumor growth in AML bearing mice.
Summary/Conclusion: In summary, our findings suggested that HDAC1 contributed to the multidrug resistance of AML and its function turnover was regulated, at least in part, by epigenetic modifications, including neddylation and ubiquitination.

PB1659

EARLY REDUCTION OF WT1 TRANSCRIPT LEVEL DURING INDUCTION CHEMOTHERAPY PREDICTS FOR LONGER RELAPSE-FREE AND OVERALL SURVIVAL IN ACUTE MYELOID LEUKEMIA

L. Girshova[1,*], I. Budaeva[2], E. Ovsiannikova[2], K. Bogdanov[3], T. Nikulina[3], J. Mirolubova[3], D. Motorin[1], A. Zaritskey[1]

[1]hematology, [2]Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russian Federation, [3]Clinical diagnostic laboratory, Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russian Federation

Background: Intensive chemotherapy allows to obtain complete remission (CR) rates ranging from 50 to 80% in adult patients with acute myelogenous leukemia (AML), but relapses still occur in 40–50% of cases. The cause of relapse is the persistence of tumor clones during therapy. The early response to the first course of chemotherapy is a marker of high chemosensitivity. It was shown by AMLCG that bone marrow blast level on day 14th of 1st chemotherapy cycle is predictive for remission rate, OS, RFS. RQ-PCR is much more sensitive than morphology for the identification and quantification of small blast populations in the bone marrow. The Wilms' tumor gene 1 (*WT1*), which is overexpressed in more than 90% of AML, is a useful marker for monitoring MRD. Quantification of *WT1* transcript level in bone marrow (BM) at day 14 induction chemotherapy could more precisely discriminates patients at different risks of relapse than the number of blast cells.
Aims: To determine the clinical significance of *WT1* overexpression level at the day 14th of the first chemotherapy cycle.
Methods: 51 *de novo* AML pts median age 42,7 (range from 16 to 70) with overexpression *WT1* were included in the study. «7+3» and «FLAG» were used for remission induction. Median of follow up was 18 mo. Bone marrow was aspirated prior to the start of chemotherapy and on the 14th day of induction treatment. *WT1* expression was evaluated by the *WT1* ProfileQuant (protocol EAC) kit (IPSOGEN) following the manufacturer's instructions. A value more than 250 *WT1*/10^4 copies ABL was considered abnormal after being compared with samples from healthy donors.
Results: 86,3% (44/51) pts had AML remission. Median of *WT1* level on the 14th day was 617copies/10^4 ABL (range from 3,7 to 19257,7). The remission rate did not depend on the achievement of normal expression of *WT1* on day 14 (p=0.11). However, there was a significant difference in values of *WT1* at day 14±3 in the patients with and without CR (740.0 *vs* 4616.21 copies/10^4 ABL, p=0.0051). Pts with early (less than 6 mo) relapse had overexpression *WT1* at day 14 (>250 WT1/10^4 copies ABL) (88,9% *vs* 0%, *p=0,001* Fisher exact test, two tailed, 100% sensitivity, 78% specificity). RFS and OS were more durable in pts with *WT1* less than 250 copies (42,8mo *vs* 6,3mo, p=0,0003 and not reached median *vs* 10,4mo, p=0,009). There was a correlation between the normalization of *WT1* at day 14 and the risk group (p=0,019). Intermediate risk group was divided into two: the pts with overexpression *WT1* had lower RFS 6,2 *vs* 10mo (p=0.026). 65,7% (23/35) the pts with <10% blasts on the 14th day had overexpression *WT1*. These pts had early (less than 6 mo) relapse: 84,6% (11/13) *vs* 0% (0/7) (p =0,002). The cut-off level of *WT1* transcript level decrease to predict early relapse is 1.1 log. In multivariate analysis including risk group, CR after the first induction course, blast percentage at day 14, level *WT1* at 14 and 28 days, independent prognostic factors for RFS were level *WT1* at day 14 and risk group (HR:8.66; 95% CI: 1,6-46.7; p=0.01 and HR:2.35; 95% CI: 1,0-5.3; p=0.04).

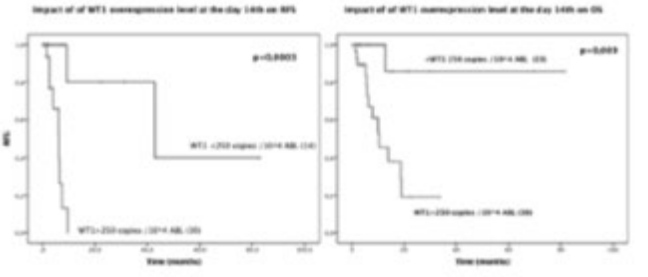

Figure 1.

Summary/Conclusion: *WT1* transcript level on day 14 of the first induction cycle is predictive for early relapse, RFS and OS. It is more sensitive that blast level. *WT1* transcript level can discriminate intermediate prognosis pts into better and poorer prognosis.

PB1660

ANTI-CD CELL-BINDING ANTIBODY MICROARRAY FOR INTEGRATION OF MORPHOLOGY AND IMMUNOPHENOTYPING IN ACUTE LEUKEMIA DIAGNOSIS

O. Fedyanina[1,2], A. Zakirova[1], A. Zadorozhnaya[3], S. Kuznetsova[1,2,*]

[1]Biophysics, National Research Centre for Pediatric Hematology, Oncology and Immunology, [2]Centre for Theoretical Problems of Physico-Chemical Pharmacology, [3]Faculty of Physics, Lomonosov Moscow State University, Moscow, Russian Federation

Background: Acute leukemia diagnosis requires the integration of morphology and flow cytometry data. However, it is not always straightforward due to the difference in the method for blast identification used in both cases.
Aims: To simplify the integration of morphology and immunophenotyping we have developed an anti-cluster-of-differentiation (anti-CD) antibody microarray on a transparent support for leukocyte sorting and a method for preparation of the microarray-bound cells for high-resolution morphology analysis.
Methods: The suspension of mononuclear cells separated by density gradient from bone marrow aspirate is incubated with the microarray in non-mixing conditions. After the unbound cells are washed away the bound cells are dried and flattened in a home-developed cytocentrifuge. The drying/flattening procedure makes the microarray-bound cells morphologically identical to the same cells in a smear and suitable for other standard smear-oriented techniques such as cytochemistry while the leukocytes on the microarray are grouped according to their surface CD antigens. Due to the non-mixing incubation the density of the cells bound to an anti-CD antibody permits to determine the fraction of cells positive for the corresponding CD antigen with high correlation with flow cytometry.
Results: We studied 66 patients with diagnosed acute leukemia of different subtypes and showed that the morphology of the microarray-bound blast cells was identical to the same cells in smears, the percentage of blast cells was in good correlation with the results obtained by flow cytometry and smear analysis and the blast immunophenotype determined as the list of anti-CD antibodies binding the leukocyte population with more than 2% of cells with blast morphology agreed well with flow cytometry results. Then we have compared the blast percentage among anti-CD45-bound bone marrow mononuclear cells for 23 nonneoplastic bone marrow aspirates, 17 samples from patients with chronic myelocytic or myelomonocytic leukemia and 90 bone marrow aspirates from patients with acute leukemias. The threshold for acute leukemia was found to be 25%. Finally we show that morphology and cytochemistry analysis of mononuclear bone marrow cells from patients with suspected acute leukemia bound by anti-CD antibody microarray including monoclonal antibodies against CD1a, CD2, CD3, CD4, CD5, CD7, CD8, CD10, CD11b, CD11c, CD13, CD14, CD15, CD16, CD19, CD20, CD22, CD33, CD41, CD45, CD61, CD64, CD117,

CD235, IgM, HLA-DR and negative control permits to arrive at preliminary diagnosis by FAB classification.

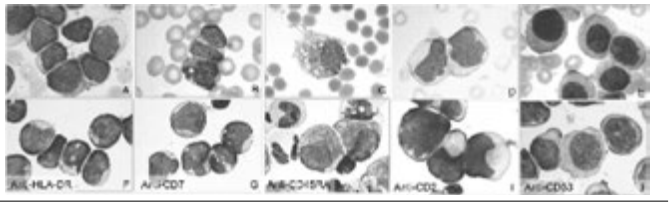

Figure 1.

Summary/Conclusion: The anti-CD morphology microarray can help in integration of morphology and flow cytometry data in differential diagnosis of acute leukemias and is a potentially useful diagnostic tool in resource-poor countries. The work was partially supported by gran #18-015-00272 from Russian Foundation for Basic Research.

LOW-MYELOPEROXIDASE (MPO) MIXED-PHENOTYPE ACUTE LEUKEMIAS (MPALS) IDENTIFIED BY COMBINING CYTOCHEMISTRY AND FLOW CYTOMETRY

E. Kritikou-Griva[1], E. Goumakou[1], S. Papadhimitriou[1], G. Androutsos[1], D. Pavlidis[1], N. Tsagarakis[1], G. Paterakis[2,*]

[1]Laboratory Hematology, [2]Flow Cytometry Laboratory, Department of Immunology, General Hospital of Athens "G. Gennimatas", Athens, Greece

Background: Mixed-phenotype acute leukemias (MPALs) are rare leukemias often presenting with difficulties of classification and treatment. According to the revised WHO 2016 criteria, the identification of their myeloid component still relies on the expression of MPO, yet a new subgroup of otherwise typical B-ALLs with low levels of MPO has been recognized of unknown clinical significance up to now.
Aims: This study is a meta-analysis of our cohort of MPALs, the recent WHO revision taken in account.
Methods: In a total of 700 *de novo* adult acute leukemias 24 (3.4%) were classified as MPAL according to WHO 2008 by multi-color flow cytometry (FC), using CDs 19,79a, 10, 20 as B-lineage markers, CDs 3, 2, 5, 7 as T-lineage and cytoplasmicMPO (cut-off 10%), c13, s13, s33, 117 as myeloid markers. Cytochemical MPO (cut-off 3%) was also evaluated in all cases. Karyotype and FISH defined genetic groups.
Results: 16/24 MPALs were B+M and 8/24 T+M. Discordance of cytochemistry and FC for MPO determination was found at 10/24 MPAL cases (41.7%), that is 9 MPO-positive cases identified only by cytochemistry and 1 only by FC. All discordant cases had isolated low MPO expression (4-20% positive blast cells) and an immunophenotype of Pro-B (5), pre-B (1), common B (1), pre-T (2) and mature T(1) ALL, without any other markers of myeloid differentiation. Interestingly, 3 of these cases clearly co-expressed MPO and lymphoid markers at relapse by FC as well. According to cytogenetic data, 50% of the B+M MPALs were BCR/ABL- or MLL- associated and all but one of the "MPO- discordant" cases belonged to these genetic groups.
Summary/Conclusion: The determination of an isolated low-intesity MPO in MPALs may be challenging, due to the lack of an established threshold for FC and to technical reasons. The WHO 2016 revision draws attention to a group of acute leukemias with B-cell phenotype and low MPO expression of unknown clinical significance. In this study almost 50% of our B+M MPAL cases, all but one being MLL- or BCR/ABL- associated, matched this description and it was the combined cytochemical and FC approach for MPO that disclosed their myeloid component, as well as at a few T-ALLs. In our experience this combination is most helpful for the better identification of these rare MPALs with isolated low MPO.

PB1662

DETECTION OF CALR AND CBL MUTATIONS BY NEXT GENERATION SEQUENCING (NGS) IN ACUTE MYELOID LEUKEMIA (AML) AND MYELODISPLASIC SYNDROME (MDS)

C. Cuéllar[1,*], Y.P. Cánaves[2], E. Onecha de La Fuente[3], J.M. Sánchez[4], I. Rapado[4], J. Martínez López[4], R. Ayala[4]

[1]Hematology, Hospital Universitario de La Princesa, Madrid, Spain, [2]Hematology, Policlínico PAMI I, Rosario, Argentina, [3]Biología Molecular, [4]Hematology, Hospital [12] de Octubre, Madrid, Spain

Background: With the advent of NGS, an extended spectrum of molecular abnormalities has been discovered. However, the correlations between most somatic mutations and clinical characteristics and the underlying mechanisms still need further investigations. In AML, several mutations (FLT3-ITD, NMP1, DNMT3, CEBPA, TET2, IDH1/2) are already described with known implications in prognosis and clinical evolution. However, little is known about CALR and CBL mutations in AML and MDS. As known, Calreticulin (CALR) plays important roles in calcium homeostasis, protein folding, cell proliferation, apoptosis and inmune response. CALR is the second most frequently mutated gene in myeloproliferative neoplasms (MPNs). Casitas B-cell lymphoma (CBL) is an E3 ubiquitin ligase and promotes ubiquitination-directed degradation of target proteins (EGFR, FLT3, KIT, MPL and Src). Loss of E3 ligase activity together with additional gain-of-functions induced by these mutations promote malignant transformation.
Aims: To report and to describe the frequency of atypical mutations in AML ans MDS, focused on CBL and CALR detected by NGS myeloid panel.
Methods: We performed a custom-targeted sequencing panel of 32 genes (all coding regions) implicated in leukemia prognosis, including ASXL1, CBL, DNMT3A, EPOR, ETV6, EZH2, FLT3, HRAS, IDH1, IDH2, JAK2, KDM6A, KIT, KRAS, LNK, MLL, MPL, NRAS, PHF6, PRPF40B, PTEN, RUNX1, SF1, SF3A1, SF3B1, SRSF2, TET2, TP53, U2AF35, VHL, ZRSR2 and CALR, by Ion Torrent Proton System-Thermo Fisher. Kaplan- Meier survival curves and Long-rank test were used for estimation of survival and difference between groups.DNA samples collected between 2012 to 2018 years from a cohort of 335 patients with myeloid pathologies were screened by NGS. Among all studied patients, 190 (53,5%) were male and 165 (46,5%) female. 231 (65,1%) had AML diagnosis, 77 (21,7%) myelodisplasic syndrome (MDS), 42 (11,8%) chronic myeloproliferative syndrome (NMP), 3 (0,8%) medular aplasia and 2 (0,6%) other pathologies.
Results: Out of 77 patients with MDS, 8 (10%) were positive for CBL and 20 (26%) for CALR mutation. There were 20 deaths in the MDS group, none of them had CALR mutation and just one patient had CBL mutation. In NMPS, 2 (4%) patients were positive for CBL and 4 (10%) for CALR mutation. In AML cohort, 13 (5,6%) were CALR positive and 15 (6,5%) CBL positive. 114 (49,5%) of AML patients were deceased, of which 5 (4%) were CALR and 9 (8%) CBL positives These results were not statistically significant (p >0.05). We observed an unusual location of CALR mutation, mostly SNV in exon 5, instead of indels in exon 9, the typical location in NMPs. We detected a hotspot location of mutations in the ring finger domain of CBL similar to the ones described in previous publications. Median OS were 18 months for CALR negative AML group *vs* not reached median OS for CALR positive AML group (p=NS). Median OS were 71 months for CALR negative MDS group *vs* 108 months for CALR positive MDS group (p=NS)

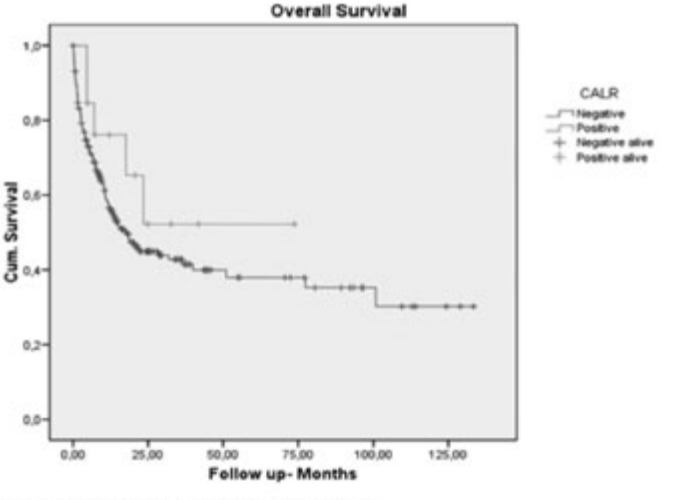

Figura 1. Kaplan Meier curve. OS CALR in AML.

Figure 1.

Summary/Conclusion: These results reveal a possible correlation between CALR gene mutation and prognosis features in AML or MDS patients. Despite of the lack of statistical significance, routine diagnostic approach of this gene could improve prognostic prediction. Moreover, it could be a therapeutic target, leading us to an individualized treatment. On the other hand, we could not find any correlation betweeen CBL mutation and MDS or AML and its prognosis. Therefore, larger controlled studies are necessary to confirm the findings.

PB1663

CLINICAL SIGNIFICANCE OF CONNEXIN 43 AND CONNEXIN 32 AS NEW PROGNOSTIC MARKERS IN ACUTE MYELOID LEUKEMIA

A. Shams[1], D. Gamil[1], M. Fateen[1], A. Seif[1], R. Salama[2,*]

[1]Clinical and Chemical Pathology Department, [2]Clinical Oncology Department, Cairo University, Cairo, Egypt

Background: Acute myeloid leukemia (AML) is the most common type of hematological malignancy. It seems likely that gap junctions are involved in the communication between AML and stromal cells during disease development. Gap junctions consist of arrays of intercellular channels composed of two hemichannels or connexons, one of which is formed by six protein subunits, termed connexins (Cxs). Cxs are a conserved family of transmembrane proteins which regulate the passage of biological molecules and allow the exchange of signaling molecules between the cytoplasm of two neighboring cells. Cx43 is the major component of hematopoietic tissue and Cx32 is found on bone marrow stromal cells.
Aims: The aim of this study was to evaluate the expression of Cx 43 and Cx 32 expression profiles and to correlate their expression with disease severity and other prognostic markers in patients with AML.
Methods: This study was carried out on samples from the peripheral blood of 60 patients with AML. Detection of Cx 43 and Cx 32 expression was performed using real time polymerase chain reaction (RT-PCR)
Results: The cases were divided into 39 males (57.4%) and 21 females (42.6%). Their age ranged between 14 and 82 years with a mean value of 49.68±16.1. Cx 32 expression showed a high median fold change along with a statistically significant difference between *de novo* AML patients and the control group (median Cx 32=18, p=0.009). On the other hand, Cx 43 expression showed a lower median fold in comparison to the control group (median Cx 43=0.6, p=0.013). A lower median fold change was observed in Cx 32 expression (median Cx 32=0.48), and Cx 43 expression (median Cx 43=0.1) in FAB subtype (M3) when compared with other FAB subtypes as (M1, M2, M4, M5).There was a statistically significant difference between the groups (Cx 32, p=0.009; Cx 43, p=0.002, respectively). In addition, CD34 positive AML patients showed a significantly higher level of Cx 32 (median Cx 32=20), and Cx 43 expression (median Cx 43=0.7) against CD34 negative AML patients (median Cx 32= 0.16; median Cx 43=0.7) (Cx 32 p=0.045; Cx 43 p=0.007). No statistically significant difference was found between favorable risk patients and those with intermediate/unfavourable risk in Cx 32 and Cx 43 fold change expression.
Summary/Conclusion: Our results indicate that Cx 43 and Cx 32 may have a role in AML pathogenesis.Further studies needed to evlauate their clinical significance as prognostic factors in AML.

PB1664

THE PROLIFERATION INDEX OF BONE MARROW CELLS FOR DIFFERENTIAL DIAGNOSIS OF CHRONIC MYELOMONOCYTIC LEUKEMIA *VS* ACUTE MONOBLASTIC/MONOCYTIC LEUKEMIAS

P. Leoz*, A. Berkovits, V. Guerri, C. Fernández, S. Barrena, A. López, J. Ciudad, M. Fierro, R. Rivas, M. Santos, A. Orfao, S. Matarraz

Centro de Investigación del Cáncer (IBMCC, University of Salamanca-CSIC), Salamanca, Spain

Background: Overlapping features often hamper the differential diagnosis of chronic myelomonocytic leukemia (CMML) *vs* acute monoblastic/monocytic leukemias (AMML).
Aims: We investigated the proliferation index (PI) of different bone marrow (BM) cell subsets by multiparameter flow cytometry as potentially useful for discrimination of both disease entities.
Methods: The PI (percentage of cycling S+G2/M cells) was studied using a 4-color (CD34/CD45/CD11b/CD13) antibody panel that included the DRAQ5 DNA stain. Thus, a total of 145 BM samples corresponding to healthy subjects (NBM; n=67), CMML (n=31; CMML-1, n=25 and CMML-2, n=6) and AMML (n=47; monoblastic leukemia, n=38 and monocytic leukemia, n=9) were studied for the PI among the more immature BM cell component in each case (*i.e.* CD34+ cells and/or leukemic cells) and also (residual) monocytic, neutrophil and erythroid lineage cells.
Results: As expected in NBN, the highest PI was shown by erythroid cells, followed by $CD34^+$ hematopoietic precursors, neutrophil and monocytic cells (PI of 28%, 15%, 5% and 4%, respectively). Conversely, the analysis of the more immature BM cell component from monocytic leukemias revealed that CD34+ cells from CMML patients had normal proliferation rates (PI of 16% *vs* 15% in NBM), while significantly decreasing in AMML (CD34+) leukemic cells (7% *vs* 15%; p<0.001). In detail, the PI of CD34+ cells from CMML-1 was significantly higher *vs* (CD34+) leukemic cells from monoblastic and monocytic leukemias (PI of 17% *vs* 7% and 4%, respectively; p<0.001), while a similar PI was found among CD34+ cells from CMML-2 *vs* leukemic cells from both groups of AMML patients (PI of 3%; p>0.05). As noted, a tendency to a lower PI of the (CD34+) blast cell compartment is observed from monoblastic to monocytic leukemia (7% *vs* 4%, respectively; p>0.05). In turn, AMML monocytic-lineage leukemic cells depicted a significantly increased proliferation *vs* monocytic cells from both NBM and CMML (PI of 7% *vs* 4% and 3%, respectively; p=0.001). Such overall increased PI was mostly related to the enhanced proliferation of monoblastic leukemia cells, which was almost twice the PI of monocytic cells from all the other groups (PI of 7% *vs* 3%, 3% and 4% for LMMC1, LMMC2 and monocytic leukemia, respectively; p=0.001). Most strikingly, the proliferation of the erythroid-lineage cells was found significantly decreased in AMML, as compared to NBM (PI of 25% *vs* 28%: p=0.02). Interestingly, this was at the expense of erythroid cells from monocytic leukemia, which showed a significantly lower proliferation *vs* all the other groups (PI:15% *vs* 27%, 30% and 23% for monoblastic leukemia, CMML-1 and CMML-2, respectively; p=0.005). No differences were found in the PI of any other residual cell lineage investigated.
Summary/Conclusion: The detection of decreased levels of proliferation, particularly among erythroid cells might help the differential diagnosis of CMML-2 *vs* monocytic leukemia, whereas an enhanced proliferation of leukemic cells is particularly recurrent in monoblastic leukemia *vs* the other monocytic lineage leukemias investigated.

PB1665

BONE MARROW LYMPHOCYTE PROFILE OF HLA-DR NEGATIVE NON-M3 ACUTE MYELOID LEUKEMIA

S. Cingelova[1,*], A. Mlcakova[2], E. Mikuskova[1], L. Demitrovicova[1], I. Oravcova[1,3], V. Mikudova[1], S. Kevicka[1], A. Slobodova[2], J. Gyarfas[1], M. Mego[3,4], L. Drgona[1,3]

[1]Oncohematology, [2]Laboratory Hematology, National Cancer Institute, [3]Faculty of Medicine, Comenius University, [4]Oncology, National Cancer Institute, Bratislava, Slovakia

Background: The impact of the bone marrow microenvironment on the behaviour of hematopoietic neoplasms is being increasingly studied. Human Leukocyte Antigen (HLA) Class II molecules play an essential role in presenting antigenic peptides to regulatory T-cells and in the generation of an immune response. HLA Class II molecules are expressed on acute myeloid leukemia (AML) blasts at diagnosis in most cases of non-M3 AML. The biological and clinical significance of HLA-DR antigen loss is not known.
Aims: We aimed to study a bone marrow lymphocyte profile (infiltrating lymphocytes) of HLA-DR negative non-M3 AML and possible association with bone marrow blast percentage and treatment outcome.
Methods: A total of 73 newly diagnosed patients with non-M3 AML admitted at National Cancer Institute Bratislava, Slovakia, between years 2012 and 2017 were included in this study. A diagnosis of AML was made based on the results of morphology, immunophenotype and genetics. An association between immunophenotypic characteristics of bone marrow blasts, bone marrow lymphocyte profile and blast percentage was evaluated by Kruskal-Wallis one-way ANOVA test, and for overall survival evaluation and response rate were used log-rank test and Fisher exact test, respectively, for multivariate analysis Cox regression and logistics regression models with AML genetic risk group, as appropriate.
Results: Patients were immunophenotypically characterized as HLA-DR positive (65 pts, 89%) or HLA-DR negative (8 pts, 11%). HLA-DR negativity was associated with CD11b negativity (100%) and CD34 negativity (62.5%). HLA-DR negative patients had significantly higher bone marrow blast percentages (median 92.2% *vs* 63.3%, *P*=0.005), lower bone marrow lymphocyte count (median 3.5% vs.8.0%, *P*=0.01) and lower bone marrow T-lymphocyte count (median 2.5% *vs* 6.8%, *P*=0.007), with no significant difference in B-lymphocytes or NK-cells. Infections rate, overall survival and treatment response rate showed no significant differences between the HLA-DR negative and the HLA-DR positive group.
Summary/Conclusion: HLA-DR antigen loss is not frequent in myeloid leukemogenesis, and may represent mechanism of immune escape. HLA-DR negative AML cases have bone marrow lymphocyte profile distinguishable from those of typical AML, which needs further investigation. Understanding the role of the immune microenvironment in the behaviour of AML is of great importance, especially with the success of immunomodulatory treatment.

IN VITRO AND *IN VITRO* MODELS OF ACUTE MYELOID LEUKEMIA USING CRISPR/CAS9 SYSTEM

E. Gonzalez[1,*], A. Rosal-Vela[1], B. de Matteo[1], M. Ibañez[2,3], A. Liquori[1,4], A. SanJuan[5], C. Sargas[1], M. Boluda[1], C. Martínez[1], M. Llop[4,6], L. Cordón[4,7], E. Barragan[4,6], A. Neef[1], G. Sanz[2], M.Á. Sanz[2], J.M. Millán[8,9], R. Vázquez[8,9], J.V. Cervera[10]

[1]Research Group in Hematology, Instituto de Investigación Sanitaria La Fe, [2]Hematology Service, Hospital Universitario y Politécnico La Fe, Valencia, [3] CIBER de Oncología (CIBERONC), [4]CIBER de Oncología (CIBERONC), [5]Research Group in Hematology, Instituto de Investigación Sanitaria La Fe, Madrid, [6]Molecular Biology Service, Hospital Universitario y Politécnico La Fe, [7] Flow Cytometry Lab, Hematology Service, [8]Research Group in Molecular, Cellular and Genetic Biomedicine, Instituto de Investigación Sanitaria La Fe, Valencia, [9]CIBER de Enfermedades Raras (CIBERER), Madrid, [10]Hematology Service, Instituto de Investigación Sanitaria La Fe, Valencia, Spain

Background: Acute Myeloid Leukemia (AML) is a complex heterogeneous disease produced by clonal expansion of undifferentiated myeloid precursors, resulting in impaired hematopoiesis and bone marrow failure. Whole-genome sequencing and advances in next-generation sequencing have increased our knowledge of the molecular heterogeneity of AML, and have these insights been translated into improved disease classification. The *IDH2*^{R172} mutations have been proposed to constitute an independent subgroup into this classification, different from the rest of mutations in this gene. For understanding the role of these mutations in the leukemia progress and for the development of specific therapies is necessary to create new AML models. The CRISPR/Cas9 system has allowed a great advance in genome engineering due to its easy design and use in different model organisms. With this system is possible to develop AML models with single mutations or introduce them progressively to characterize the acquired driver mutations detected in patients.
Aims: We want sought to develop *in vitro* and *in vivo* models of AML using the CRISPR/Cas9 system to introduce *IDH2* mutations. Objectives: Development of an easy and fast method to produce guide sequences; Introduce *IDH2*^{R172K} mutation in leukemia cell lines; Introduce *IDH2*^{R172K} and *IDH2*^{R140Q} mutations in the nematode *Caenorhabditis elegans*. Due to the homology between the gene in model organism and humans this is feasible (the R172 and R140 amino acids are conserved).
Methods: To do the *in vitro* model, we have developed a fusion PCR system for generating constructs with the sgRNA sequences and the pU6 promoter, and optionally, adding the GFP reporter. These constructs were transfected in the broadly used HEK293 cells, and these constructs are able to cut the target genes. After a series of optimizations we have used these constructs in leukemia cell lines that express Cas9 to produce our model. Furthermore, we used ribonucleoprotein (RNP) complex in cells without Cas9 expression to compare the efficiency of the different procedures. We have also introduced the *IDH2*^{R172K} and *IDH2*^{R140Q} mutations in *C. elegans.* To do so we prepared a mix with RNP and an oligonucleotide, as an editing template carrying the desired mutation, were injected along with a gRNA against a gene which produces easy-to-see phenotypes, as a marker of edition. With a PCR with specific primers we isolated homozygote worms with each mutation.
Results: With the optimization in HEK293 cells we selected the best sgRNA combination to modify *IDH2* gene (20% of efficiency). Interestingly, we obtained the same efficiency in NB4 cell line which contained an insertion that induces constitutive expression of Cas9. The RNP complex was used in the NB4 cell line with 8% of efficiency. In future experiments we will introduce *IDH2* ^{R172K} using these two methodologies. On the other hand, the marker phenotype let us isolate those worms that were efficiently edited, among which we were able to isolate worms carrying *IDH2* ^{R172K} or *IDH2*^{R140Q} mutations.
Summary/Conclusion: The CRISPR/Cas9 technology represents a high biomedical revolution that has already been used in multiple fields. Specifically, this system can be used to elucidate the functional and cooperating effect of the mutations detected in patients with AML. We have used this technique to develop two AML models in which we can introduce mutations detected in patients in a sequential way, study the effect in the leukemic phenotype and could be a promising platform to test new drugs against this disease.

PB1667

APPLICATION OF THE GENEREADER NGS SYSTEM AND QIAACT MYELOID DNA UMI PANEL IN DETECTING RELEVANT MUTATIONS FOR MYELOID LEUKEMIA RESEARCH, INCLUDING FLT3 ITDS

V. Laloux[1,*], O. Biglia[2], A. Bona[2], S. Lafi[2], F. Charifi[2], L. Schauser[3], J. Larsen[3], D. Lueerssen[4], V. Gupta[3], J. Lauber[5], S. Hughes[4]

[1]QIAGEN, Courtaboeuf, [2]HalioDx, Marseille, France, [3]QIAGEN, Aarhus, Denmark, [4]QIAGEN, Manchester, United Kingdom, [5]QIAGEN, Hilden, Germany

Background: Myeloid malignancies comprise many different subtypes amongst which myeloproliferative neoplasms (MPN), myelodysplastic syndrome (MDS), myelodysplastic/myeloproliferative neoplasms (MDS/MPN) and acute myeloid leukemia (AML), are associated with somatic mutations acquired in around 20-30 key genes. To detect these relevant myeloid malignancy-related genetic variants, a targeted enrichment approach coupled to NGS analysis nicely complement the individual biomarker tests to provide a comprehensive mutational overview. The QIAact Myeloid DNA UMI Panel in combination with the QIAGEN GeneReader™ NGS System provides an integrated solution to simultaneously interrogate many candidate genes for actionable mutations, from as little as 40 ng input DNA, shortening test time and enabling simplification of lab operations. The QIAact Myeloid DNA UMI Panel is a 25-gene targeted sequencing panel for markers of known significance to clonal myeloid malignancies, allowing reliable and sensitive detection of single nucleotide variants (SNV) and large Insertion/Deletion (InDel) mutations.
Aims: To assess the QIAact Myeloid DNA UMI Panel performance in combination with the QIAGEN GeneReader NGS System.
Methods: Following the advice from key opinion leaders in the field of blood cancer disorders, the QIAact Myeloid DNA UMI Panel has been designed to detect relevant mutations throughout the most informative genes linked to myeloid disease. A key feature of the panel is the addition of a unique molecular index (UMI) to tag individual molecules prior to target enrichment by PCR. This enables sequencing and PCR bias correction, allowing sensitive detection of mutations (e.g. below 1% MAF for *JAK2* (exon 12, 13, 14 & 15) & *KIT* (exon 8, 9, 10, 11 & 17). To assess the assay performance, control samples and blood and bone marrow samples were used. Following target enrichment, libraries were sequenced on the GeneReader™ NGS system and mutations identified using the QIAGEN Clinical Insight (QCI™) Analyze software suite, adjusted to specifically support variant calling in this assay.
Results: Complex mutations like the 52 bp deletion CALR type 1 variant, FLT3 ITDs up to 121 bp insertion and NPM1 insertions were efficiently identified. Limit of detection testing using the power of UMIs demonstrated uniform amplification and sequencing coverage to consistently detect mutations with a 1% MAF and below for JAK2 and KIT (KIT D816V variant can be detected at 0.2%), and 5% for all the other genes covered by the panel. Overall mutational variants were correctly called, resulting in >99% concordance with an alternative testing technology.
Summary/Conclusion: The QIAact Myeloid DNA UMI Panel in combination with the QIAGEN GeneReader NGS System offer a fully integrated sample to insight solution. The optimized chemistry allows superior analytical sensitivity in accurately detecting highly relevant genetic alterations for myeloid malignancy research.

ANTI-LEUKEMIC EFFECTS OF VOSAROXIN, AN ANTI-CANCER QUINOLONE DERIVATIVE, ON HYPOMETHYLATING AGENT-RESISTANT CELLS

H.-S. Park*, E.-H. Hur, B.-K. Goo, J. Moon, S.-H. Ko, E.-J. Choi, K.-H. Lee, J.-H. Lee, J.-H. Lee

Department of Hematology, Asan Medical Center, Seoul, Korea, Republic Of

Background: Although two hypomethylating agents (HMAs), azacitidine and decitabine, are widely used for treatment of patients with myelodysplastic syndrome (MDS) and elderly acute myeloid leukemia (AML), most patients eventually experience resistance to the agents. Vosaroxin, an anticancer quinolone derivative, acts as a topoisomerase II inhibitor, and improved survival in a phase 3 study of vosaroxin in combination with cytarabine in relapsed/refractory AML.
Aims: We investigated anti-leukemic effects and mechanism of action of vosaroxin in HMA resistant cells.
Methods: We established three HMA resistant cell lines: MOLM/AZA-1 and MOLM/DEC-5 from MOLM-13 (AML/MDS cell line [*Oncotarget* 2017;8:11748]), and THP/DEC-2 from THP-1 (AML cell line). Cell viability was performed using Celltiter-glo luminescent cell viability assay (Promega, WI) and Operetta high-content imaging system (PerkinElmer, MA). The cell cycle distribution was determined by propidium iodide staining and flow cytometry. The proteins of apoptosis and cell cycle regulator were detected with immunoblot assay using specific primary antibodies.

Results: Vosaroxin caused dose-dependent inhibition of HMA resistant cells as well as MOLM-13 and THP-1 cells, and IC50 values of vosaroxin were significantly lower than those of azacitidine or decitabine. Vosaroxin induced increase of nuclear size in all cell lines except MOLM-13, in which DNA fragmentation was induced. DNA flow cytometric analysis exhibit G2/M arrest by vosaroxin. The immunoblotting showed increase of p53 and p21 expression in MOLM-13, MOLM/AZA-1 and MOLM/DEC-5 cells, increase of CDK2 and CDK4 expression, and decrease of Rb expression. Synergistic effects with combination of vosaroxin with decitabine were found in THP-1 and THP/DEC-2. Vosaroxin exerted *in vitro* anti-leukemic effects in 20 of 26 bone marrow samples from MDS patients.
Summary/Conclusion: Our preclinical studies demonstrated excellent anti-leukemic activities of vosaroxin in our HMA resistant models, and the effects seem to be attributed to cell cycle regulation of vosaroxin.

ASYNCHRONOUS MONOCYTIC MATURATION PATTERN IN AML WITH NPM1 MUTATION

M.Á. Álvarez Juárez[1,*], I. Carmona Zabala[1], I. Martín Rubio[1,]
J. Galán Vega[1], C. Escolano Escobar[1], F. Herrera[1], A. Yeguas Bermejo[2], N. Somolinos de Marcos[1], A.M. Hernández-Sánchez[3], L. Benito Parra[1], M.C. Monteserín[1], L. García Alonso[1], F. Oña Compán[1], J.A. García Vela[1]

[1]Hematology department, Hospital Universitario de Getafe, [2]Hematology department, Fundación Jiménez Díaz, Madrid, [3]Hematology department, Hospital Quirón Salud, Málaga, Spain

Background: Associations between immunophenotypic findings (IF) and genetic abnormalities have been proved for specific subtypes of AML harboring recurrent cytogenetic abnormalities. Mutation of the nucleophosmin gene (NPM1) is observed in approximately 30% of cases of AML, and is recognized as a distinct entity in the World Health Organization classification. It most commonly falls in the M1/M2 (myeloid) or M4/M5 (myelomonocytic/monocytic) FAB categories and it is associated with a favorable prognosis (although this effect is decreased in the context of concomitant FLT3-ITD mutations). There is evidence that some cases of NPM1-mutated AMLs are often negative for CD34 and HLA-Dr, showing an acute promyelocytic leukemia-like (APL-like) phenotype although there is limited information about the monocytic pattern of differentiation in these cases.
Aims: To describe the immunophenotypic pattern of the monocytic population in NPM1-mutated AMLs.
Methods: We included BM samples of 9 cases of NPM1-mutated AML (in the absence of the PML-RARA rearrangement). Staining of BM was performed as previously described using the next six-colour combinations of monoclonal antibodies: acute leukemia orientation tubes CD38/CD34/HLA-Dr/CD117/CD19/CD45 and cyMPO/cyCD79α/HLA-Dr/cyCD3/CD34/CD45, monocytic tube CD35/CD64/HLA-Dr/CD14/CD300e/CD45, granulocytic tube CD16/CD13/HLA-Dr/CD10/CD11b/CD45 and erythroid tube CD36/CD105/HLA-Dr/CD117/CD71/CD45. A minimum of 1 million of cells were acquired in a FACSCanto flow cytometer (Becton Dickinson, San Jose, CA, USA) using the FACSDiva software (BD). For data analysis the Infinicyt software (Cytognos, Salamanca, Spain) was used. Monocytic cells were identified by their expression of CD64. As previously described (Matarraz S, *et al.*, 2014) early monocytic cells (CD117low, HLA-Dr++, CD64+, CD14-, CD35- and CD300e-) sequentially acquire reactivity for CD14 and CD35 (promonocytes) and subsequently also for CD300e (mature monocytes). After selecting CD64++ cells (in monocytic cases and also in the residual monocytic cells in the myeloid cases) we identified mature monocytes by their expression of CD300e and in this target population we explored the expression of CD14 and CD35.

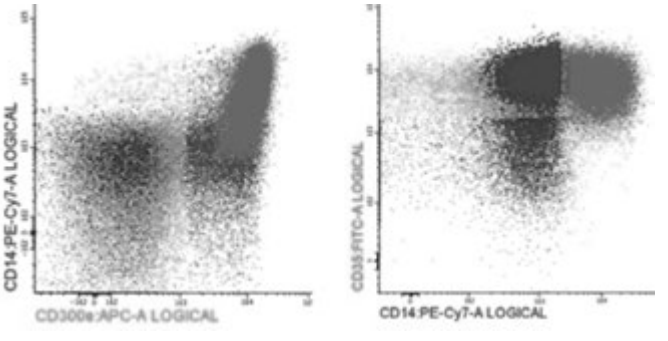

Figure 1.

Results: The cohort included 5 females and 4 males (F: M ratio=1.25), with a medium age at diagnosis of 66 years (range 42-87 years). 5 (55%) cases showed co-mutation of FLT3-ITD. 6 cases (66%) showed morphologic and immunophenotypic evidence of monocytic differentiation, while 3 (33%) of them showed ganulocytic differentiation. All cases were negative for CD34 and 2 were negative for HLA-Dr (22%) showing an "APL-like" phenotype. All cases studied showed an asynchronous maturation in the monocytic population and the expression of CD300e preceded that of CD14 and/or CD35. The average percentage of the studied population was 4.6%, with a range between 0.3% and 14% (violet population; figure 1).
Summary/Conclusion: Our results confirm previous observations regarding the asynchronous maturation in the monocytic population in NPM1-mutated AML (Matarraz S, *et al.* 2014). These preliminary results must be confirmed in a series with more cases. The expression of CD123, CD25 and CD99 should be included in future studies to explore whether their reactivity associated with the asynchronous pattern here described, can predict the association between NPM1 and FLT3 mutation.

JQ1 TREATMENT OF U937 CELL LINES OF STAT-5 SIGNAL TRANSDUCTION PATHWAYS RESEARCH

M. Liangming*

Hematology, Shan Xi Da Yi Hospital, Taiyuan, China

Background: The purpose of study is to detect change of FAK and PAK1, thus to observe the regulation of the STAT-5 signal pathway in the acute myeloid leukemia cell line (U937) which is managed by the bromo domain inhibitors-JQ1.
Aims: The purpose of study is to detect change of FAK and PAK1, thus to observe the regulation of the STAT-5 signal pathway in the acute myeloid leukemia cell line (U937) which is managed by the bromo domain inhibitors-JQ1.
Methods: With the different concentration of JQ1 to treat U937 cells, the inhibition rate of cells was detected at different times by using tetramethazolazole blue experiment (MTT). The rate of Cell apoptosis was detected by flow cytometry. The mRNA expression of level about FAK and PAK1 were detected by real-time fluorescence quantitative (rt-PCR). And the expression of stat-5 protein which was analyzed by Western Blot in each group.
Results: JQ1 can effectively inhibit the proliferation of cells and induce cellular apoptosis, and the apoptosis rate of cells is significantly much more obvious in the high group than the low one. This feature show that a time-dose dependence. JQ1 can also reduce the expression of mRNA about FKA and PAK1 with U937 cell, whenever the concentration of it. The result of Western Blot show that the abnormal expression of STAT-5 in the control group was much more higher than that in the experimental group.
Summary/Conclusion: JQ1 can effectively inhibit the growth of U937 cells by influenting proliferation and cell apoptosis. Its effect mechanism may be through to influent the expression of FAK and PAK1, thus to influent the STAT-5 signal pathway (the pathway of cell proliferation).

THE ROLE OF NA/H EXCHANGE I AS A THERAPEUTIC TARGET TO OVERCOME CYTARABINE RESISTANCE IN ACUTE MYELOID LEUKEMIA

J.-W. Cheong[1,*], S.Y. Hyun[2], E.J. Na[3], H. Chung[1], J.E. Jang[1,]
S.-J. Kim[1], J.S. Kim[1], Y.H. Min[1]

[1]Internal Medicine, Yonsei University College of Medicine, [2]Internal Medicine, Yonsei University Wonju College of Medicine, [3]Avison Biomedical Researcch Center, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Na/H exchanger 1 (NHE1), an important participant in the precise regulation system of intracellular pH (pHi), is known to be involved in pathological processes of the neoplastic disease.
Aims: In this study, we evaluated the intracellular (pHi) and NHE1 expression in acute myeloid leukemia (AML) cell lines, and whether it contributes the resistance to cytarabine (AraC).
Methods: We evaluated the pHi and NHE1 expression in AML cell lines AraC sensitive OCI-AML2 (AS-OCI) and AraC resistant OCI-AML2 (AR-OCI) cells. To modulate the NHE1 activity, the NHE1 inhibitor, 5-(N, N-hexamethylene) amiloride (HMA), and NHE1 activator, phorbol 12-myristate 13-acetate (PMA), were used. The level of apoptosis and proliferation induced by NHE1 inhibitor or activator with/without AraC was assessed at 24 hr after treatment by the annexin V assays and the CCK-8 assay.

Results: The pHi of AR-OCI cells was significantly higher than AS-OCI cells (7.839 *vs* 7.589, P=.045). Compared with AS-OCI cells, AR-OCI showed significantly higher NHE1 expression by western blot analysis, and NHE1 mRNA levels (1.565 *vs* 0.039, P<.01) by qRT-PCR. After 24hr treatment with HMA 10 ~ 30 μM, the proliferation of leukemic cells was inhibited, and the apoptosis was induced in a concentration-dependent manner, and higher concentration of HMA (30 μM) could induced apoptosis on most of AR-OCI cells. When treated by PMA with various concentration form 0.1 to 10 uM, proliferation of leukemic cells was inhibited in a concentration-dependent manner, but apoptosis was not induced. The addition of HMA 10 μM that concentration did not cause apoptosis of AR-OCI cells when treated alone to AraC treatment resulted in a significant increase in the fraction of apoptosis in AR-OCI cells (P<0.001) as compared with that of AraC treatment alone (26.33% *vs* 7.11%, P<.001). Also, the addition of PMA 1 μM to AraC treatment resulted in a significant increase in the level of apoptosis in AR-OCI cells as compared with that of AraC treatment alone (45.70% *vs* 7.11%, P<.001). These findings suggest that NHE1 plays an important role in resistance mechanism to AraC in AML cell line and NHE1 might be potential therapeutic target to overcome chemoresistance in AML. To elucidate the detailed signaling pathway after modulation of NHE1 activity, further experimental studies have been proceeding.

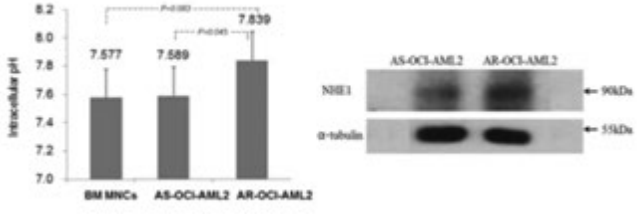

Figure 1.

Summary/Conclusion: These findings suggest that NHE1 plays an important role in resistance mechanism to AraC in AML cell line and NHE1 might be potential therapeutic target to overcome chemoresistance in AML. To elucidate the detailed signaling pathway after modulation of NHE1 activity, further experimental studies have been proceeding.

THE EFFECT OF THE CRM1 INHIBITING COMPOUND KPT-330 ON P53 ISOFORM PROFILE

E. Hajjar[1,*], V. Andresen[1,2], A. Sulen[1], S.M. Hjelle[1,2], S. Knappskog[3], J.-C. Bourdon[4], B.T. Gjertsen[1,2]

[1]Center for Cancer Biomarkers (CCBIO), Department of Clinical Science, University of Bergen, [2]Department of Internal Medicine, Hematology Section, Haukeland University Hospital, [3]Department of Clinical Science, Oncology Section, University of Bergen, Bergen, Norway, [4]Division of Cancer Research, University of Dundee, Dundee, United Kingdom

Background: The tumor suppressor *TP53* is in average mutated in about 50% of solid cancers, however, over 90% of newly diagnosed AML patients express wild type *TP53*. This could indicate different levels of dysfunctionality of the p53 protein in AML, dependent on mutational status and genetics. At least 12 different protein isoforms of p53 have been described and we have previously reported that the p53 isoforms p53β and p53γ influence full-length p53 (FLp53) function and therapy response in AML. We found that *FLT3-ITD*, a poor prognostic marker for survival in AML, correlated with expression of FLp53. In contrast, mutated *NPM1*, a prognostic marker for longer survival, correlated with p53 isoforms β and γ expression. Chromosome region maintenance 1 (CRM1) is the sole nuclear exporter for several tumor suppressor proteins including p53. CRM1 is frequently overexpressed in AML associated with poor survival. Karyopharm Therapeutics has developed several selective inhibitors of nuclear export (SINE) of proteins dependent of CRM1 for nuclear export, including KPT-330, Selinexor; currently in clinical trials for treatment of AML.
Aims: To study the effect of KPT-330 on FLp53 and p53 isoforms in AML cells.
Methods: The effect of KPT-330 on p53 isoform protein expression was studied in p53 wild type AML cell lines. The p53 expression patterns were analysed using 2-dimensional gel electrophoresis (2DE) followed by image analysis using Gel2de software which apply pixel-by-pixel Spearman rank correlation between pixel intensity and external biological parameters. In addition 1-dimensional immunoblot (1D), quantitative PCR (qPCR), immunofluorescence and flow cytometry was performed.
Results: The OCI-AML3, MOLM-13 and MV4-11 p53 wild type cell lines were characterized for p53 mRNA isoform profile (FLp53, p53β, p53γ and p53Δ133) by qPCR with the p53 null cell line HL-60 as a negative control. KPT-330 treatment for 24h of OCI-AML3, MOLM-13 and MV4-11 increased total p53 protein expression as demonstrated by 1D immunoblotting. Two dimensional gel electrophoresis immunoblotting followed by Gel2de correlation analysis to increasing dosage of KPT-330 resulted in positive correlation to FLp53 expression and negative correlation to p53β/γ isoform expression. However, no significant changes were found on the FLp53 or p53 isoform mRNA levels by qPCR. We found that the p53β protein is degraded following KPT-330 treatment through the proteosomal pathway. We are currently investigating the effect of KPT-330 on the p53Δ133 isoforms and the p53 isoform profile following cellular differentiation caused by 72h KPT-330 treatment, including changes in subcellular localization. Finally, the p53 isoform profiles of primary AML cells before and after KPT-330 *in vitro* treatment will be studied and correlated towards mutational status and drug sensitivity.

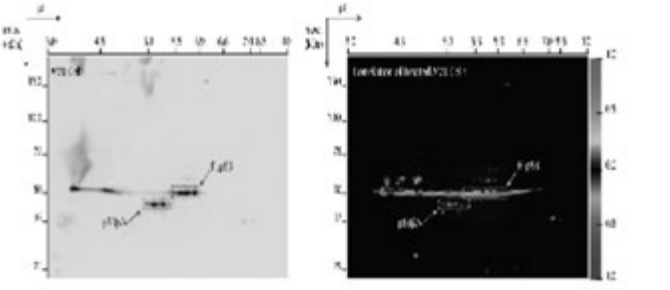

Figure 1.

Summary/Conclusion: Treatment with KPT-330 influences the p53 isoform expression profile at the protein level, where FLp53 increase and the p53β/γ decreases where p53β is degraded through the proteasome. The response of AML patients towards KPT-330 treatment could be dependent on the p53 isoform profile and be closely related to p53 dysfunction.

PHARMACOLOGICAL INHIBITION OF WIP1 SENSITIZES ACUTE MYELOID LEUKEMIA CELLS TO MDM2 INHIBITORS

M.C. Fontana[1,*], J. Nanni[1], A. Ghelli Luserna di Rorà[1], A. Padella[1], S. Bruno[1], G. Marconi[1], C. Papayannidis[1], M. Abbenante[1], S. Soverini[1], M. Cavo[1], G. Simonetti[1], G. Martinelli[2]

[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Institute of Hematology "L. e A. Seràgnoli", Bologna, [2]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) IRCCS, Meldola, Italy

Background: *PPM1D* (wild-type p53-inducible protein phosphatase, WIP1) is a serine\threonine phosphatase involved in negative regulation of cellular stress response pathways, leading to the suppression of p53. *PPM1D* mutations appeared to have oncogenic properties in many solid cancers, but their role is still unknown in acute myeloid leukemia (AML).
Aims: The aim of this study is to investigate whether the inhibition of WIP1 (GSK2830371, WIP1i) could increase the sensitivity to MDM2 inhibitor (Nutlin-3a) in order to restore p53 activity and obtain a novel therapeutic strategy for AML patients.
Methods: *in vitro* WST-1 cell-viability and Annexin V-PI apoptosis assays were performed on AML cell lines (MOLM-13, MV-4-11) and AML primary cells. The number of primary samples' viable cells was detected by Trypan Blue Exclusion Dye (Sigma-Aldrich). Whole Exome Sequencing (WES) and targeted Next Generation Sequencing (NGS) were performed to investigate the mutational state of *PPM1D* in newly diagnosed AML patients.
Results: WIP1i and Nut-3a reduced the cell viability as single agent in all the treated cells in a time and dosage-dependent manner. The IC50 values in TP53-wild type (wt) cells showed that MOLM-13 (10 mM) are more sensitive than MV-4-11 (20 mM) to WIP1i. Combination index analyses by WST1-proliferation assay confirmed that WIP1i and Nut-3a had a synergistic effect (C.I.<1) in both cell lines (Figure 1 A). Annexin V/PI staining performed after treatment with different concentration of Nut-3a (0.5 mM for MOLM-13, 15 mM for MV4-11) and WIP1i (10 mM for MOLM-13, 20 mM for MV4-11) demonstrated that the combination significantly increased the number of apoptotic cells in comparison to single agents. In particular, after 48 hours of incubation with Nut-3a and WIP1i as single agents, the percentage of apoptotic cells was 34.4% and 21.4% for MOLM-

13 and 17% and 18% for MV-4-11, respectively; while the combination induced 53.1% and 62.3% of apoptotic cells (Figure 1B). Moreover, we observed a decrease of G2/M phase cells induced by single agents, enhanced by the combination of drugs in both cell lines and, in particular, MV-4-11 were characterized by an increasing percentage of S phase cells allowing us to hypothesize that the apoptotic death induced by the combination of drugs occurs when cells are blocked in S phase. AML primary cells were also tested by Tripan Blue: we detected that the powerful combination of drugs on bone marrow AML samples at diagnosis was 5 mM of Nut3a plus 20 mM of Wip1i leading to life/death ratio of 0.77 *versus* 1.5 of single agents. Finally, by WES and targeted-NGS, 7 mutations have been detected in 2/37 and 4/96 patients at diagnosis. One patient harbored a truncating mutation on exon 6 (S468X), confirmed to be gain of function by Western Blot (WB), thus increasing the inhibition of p53; while mutations affecting exon 1 did not reveal any protein overexpression.

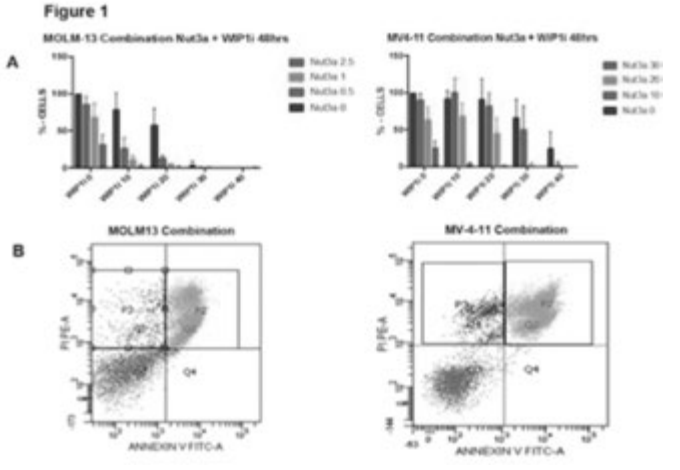

Figure 1.

Summary/Conclusion: We hypothesize for the first time that the pharmacological inhibition of WIP1 could potentiate the sensitivity to MDM2 inhibitors (Nut-3a, *e.g.* Idasanutlin) in AML patients, suggesting an important role of *PPM1D* in leukemia. Further studies will help to confirm these preliminary data: in particular, Gene Expression Profiling and WB will identify the proteins playing roles in the biological alterations induced by WIP1i alone and in cooperation with Nut-3a.

STRATEGIES OF AFFECTING CELLULAR LOCALIZATION TO OVERCOME RESISTANCE IN FLT3-ITD-POSITIVE AML CELLS

U. Schnetzke*, M. Fleischmann, M. Fischer, A. Hochhaus, F. Heidel, S. Scholl

Klinik für Innere Medizin II, Abteilung für Hämatologie und Internistische Onkologie, Universitätsklinikum Jena, Jena, Germany

Background: FLT3-ITDs (internal tandem duplication) represent the most frequent molecular aberration in acute myeloid leukemia (AML) associated with an inferior prognosis. The pattern of downstream activation by this constitutively activated receptor tyrosine kinase is influenced by the localization of mutated FLT3 depending on its glycosylation status. Different pharmacological approaches can affect FLT3-driven oncogenic pathways by distinct compartmentalization of FLT3-ITD.
Aims: The objective of this study was to investigate the effects of either valproic acid (VPA) or tunicamycin on the localization of FLT3-ITD. We sought to investigate different susceptibility of mutated FLT3 towards combination treatment-*e.g.* with inhibitors of heat shock proteins (HSP)-dependent on both the localization of activated FLT3 and the subtype of FLT3-ITD variants.
Methods: Murine Ba/F3 leukemia cell lines were stably transfected with distinct FLT3-ITD variants resulting in IL-3-independent growth (Arreba-Tutusaus *et al.* Leukemia 2016). Signal transduction after exposing cells to VPA, tunicamycin and/ or the HSP inhibitor 17-AAG was characterized by Western blotting, MTS assay and flow cytometry analysis of apoptosis, cell cycle and surface expression of FLT3.
Results: Treatment of Ba/F3-FLT3-ITD cells with VPA is associated with a significant increase of FLT3-ITD surface expression that depends on FLT3 protein synthesis. In contrast, incubation with tunicamycin leads to intracellular retention of FLT3-ITD by inhibition of its glycosylation as an important mechanism of post-translational modification. Of note, allocation of FLT3 to different cellular compartments by VPA or tunicamycin is accompanied by distinct activation of oncogenic signaling pathways. In detail, VPA is associated with an increase of AKT and ERK phosphorylation while enhanced STAT5 activation can be observed following treatment with tunicamycin. Importantly, sequential combination of either VPA or tunicamycin with the HSP inhibitor 17-AAG demonstrates additive effects that are restricted to the treatment with tunicamycin and 17-AAG.
Summary/Conclusion: We can demonstrate the impact of VPA on cell surface stabilization of FLT3-ITD that results from FLT3 biosynthesis and is associated with an enhanced activation of the AKT and ERK pathway. Combination treatment suggests that the unglycosylated form of FLT3 is more susceptible to HSP inhibitor treatment. Thus, allocation of FLT3-ITD to different cellular compartments might represent a promising therapeutic strategy to overcome tyrosine kinase inhibitor resistance in FLT3-ITD-positive AML.

PB1677

LNCRNA BALR-2-CDK6 AXIS INFLUENCES METABOLIC STATUS AND CELL DIFFERENTIATION OF ACUTE MYELOID LEUKEMIA

V. Bisio[1,*], C. Tregnago[1], G. Borella[1], M. Benetton[1], T. Fernando[2], D. Rao[2], F. Locatelli[3], G. Basso[1], M. Pigazzi[1]

[1]SDB department, Università degli Studi di Padova, Padova, Italy, [2]Path & Lab Med, UCLA, Los Angeles, United States, [3]Department of Pediatric Hematology and Oncology, IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy

Background: Non-coding RNA (ncRNAs) genes are at least as frequent as protein-coding genes in the human genome; however, our knowledge on their function is still preliminary. Their emerging role as new players in cancer development and therapy response is widely supported by several scientific reports.
Aims: Here, we aim to investigate BALR-2 involvement in pediatric acute myeloid leukemia (AML).
Methods: We retrospectively analyzed by RQ-PCR bone marrow samples of 132 children with *de novo* AML harboring different genetic abnormalities (CBF,MLL, and NUP98 rearrangements, FLT3-ITD, other rare translocations and patients without any recurrent molecular abnormality) diagnosed between 2002-2014 in one of the AIEOP centers and treated according to AML-2002/01 protocol. We compared patients' gene expression signatures (n=58, HTA affymetrix 2.0) with either high (4th quartile) or low expression (1st+2nd+3rd quartiles) of BALR-2, and used gene set and single sample enrichment analysis (GSEA, ssGSEA) to search biological differences. AML cell lines with different BALR-2 expression (high and low) were used to perform *in vitro* experiments.
Results: The expression of BALR-2 was found higher in all AML samples as compared with those collected from healthy volunteers. Moreover, we did not find any correlation between BALR-2 expression and any specific genetic subtype. We subdivided patients by using BALR-2 expression quartiles and found that patients with higher BALR-2 expression (4th quartile, n=32) had worse, although not statistically significant, EFS when compared to that of patients allocated to the 1st+2nd+3rd quartiles (n=100), butwe observed that the 4th quartile was enriched for patients who did not reach complete remission (CR) after induction therapy (28% *vs* 12%, p=0.03). Supervised clustering analyses showed that cases belonging to the 4th quartile (n=18) clustered separately from the remaining quartiles (n=40), irrespectively of the genetics. In particular, we found that patients with high BALR-2 (4th quartile) had 57 coding and 12 non-coding RNAs significantly differentially expressed (Fold Change|2|, p<0.01), and an upregulation of processes regulating mitochondrial mass and activity was found (p<0.05). We silenced BALR-2 in SHI-1 AML cell line (high BALR-2 expression) and revealed a decrease of mitochondrial mass by TOM20 staining (p<0.001), an enhanced mitochondrial depolarizion by JC1 staining, and an higher sensibility to FCCP after 6 and 24h of BALR-2 knockdown. We further

investigated CDK6, being chromosomally adjacent to BALR-2, and demonstrated a positive correlation of these genes expression levels (Pearson correlation>0.7, p<0.05). Silencing of BALR-2 *in vitro* reduced CDK6 mRNA and protein levels, as well as phospho-RB, its direct target. Noteworthy, we observed BALR-2 depletion increasing myelomonocytic differentiation, with CD11 and PU.1, both Runt-related transcription factor (RUNX1) targets, being upregulated. In agreement with these findings we showed that additional 81 RUNX1 target genes were down-regulated in patients with high BALR-2 (4th quartile) and-CDK6 expression.
Summary/Conclusion: Taken together, our data suggest that pediatric AML may have a broad heterogeneity in metabolic requirements and capacities as well as mitochondrial energetic through BALR-2 expression. We also highlight a cis-regulatory transcriptional relationship between BALR-2 and CDK6 linked to myeloid differentiation to be further dissected.

PB1678

GENOMIC-DRIVEN TRANSLATIONAL AND METABOLIC PERTURBATIONS IN ACUTE MYELOID LEUKEMIA CELLS UNDER THE SELECTIVE PRESSURE OF BROMODOMAIN INHIBITION IN THE HYPOXIC MICROENVIRONMENT

G. Simonetti[1,*], S. Bruno[1], C. Onofrillo[2], C. Papayannidis[1], G. Marconi[1], M. Cavo[1], L. Montanaro[2], G. Martinelli[3]

[1]Department of Experimental, Diagnostic and Specialty Medicine, "Seràgnoli" Institute of Hematology, [2]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Bologna, [3]Istituto Scientifico Romagnolo per lo Studio e Cura dei Tumori (IRST) IRCCS, Meldola, Italy

Background: The hypoxic microenvironment plays a crucial role in survival and chemoresistance of leukemia stem cells (LSC) in acute myeloid leukemia (AML) and shapes cell metabolism. The inhibitor of bromodomain–containing (BRD) proteins (BETi), which is effective against AML cells in normoxia, targets the transcriptional program controlled by MYC, a crucial gene controlling LSC biology and metabolic functions under hypoxia.
Aims: To investigate the role of the hypoxic microenvironment on the selective pressure of BETi treatment on AML models with different genomic background.
Methods: AML cell lines (OCI-AML3: *NPM1* and *DNMT3A* mutated, Kasumi-1: t(8;21), H-60: MYC-amplified, MOLM-13, NOMO-1: MLL-driven, KG-1) were treated for 16 or 48h with the BETi GSK1215101A (250 nM or 500 nM) after 4h-adaptation to hypoxia. Downstream analyses were performed on Kasumi-1 and OCI-AML3 cells after 16h of treatment in order to allow cell adaption to the pharmacological pressure, while avoiding massive cell death. Gene expression profiling was carried out on actively translated mRNAs isolated by polysome profiling (Affymetrix) and enrichment analysis was performed by GSEA (Broad Insititute). The metabolic profile was obtained by Liquid Chromatography-Tandem Mass Spectroscopy (Metabolon).
Results: BETi induced a dose-dependent reduction of cell viability at 48h in AML cell lines (15%>35% decrease at 250 nM and 25%>65% decrease at 500 nM) except for HL60. Kasumi-1 was the most sensitive model. The treatment caused a significant arrest in the G_0/G_1 phase of the cell cycle in OCI-AML3, Kasumi-1, HL-60 and KG-1 cells and induction of apoptosis in NOMO-1 and Kasumi-1. Kasumi1 and OCI-AML3 showed a different translational profile, the latter being more active under steady state conditions. Hypoxia and BETi reduced the translational rate of both lines, as determined by a decrease of disome-polysome peaks height. This associated with BETi-mediated downregulation of a ribosome pathway signature (p<0.001). Downregulation of the MYC transcriptional program was enriched in the translatome of both lines under hypoxia (p<0.001). The two models shared a core translational program of 86 differentially expressed genes. Additional 881 and 168 genes were altered at translational level in Kasumi-1 and OCI-AML3 cells, respectively. Moreover, the cell type strongly influenced the metabolic profile in response to hypoxia and drug treatment. Hypoxic Kasumi-1 cells showed reduced lactate levels upon treatment, which may be due to a drug-dependent decrease in lactate dehydrogenase activity and decreased asparagine levels, along with downregulation of a gene signature of alanine, aspartate and glutamate metabolism (p<0.001), including asparagine synthetase (1.5-fold decrease, p<0.01). OCI-AML3 showed a significant increase of both reduced (3.9-fold) and oxidized (2.6-fold) forms of glutathione under hypoxia, which were confirmed by colorimetric assay.
Summary/Conclusion: AML cell lines are sensitive to BETi under hypoxia, which strengthens the drug effects on MYC expression and highlights novel potential dependencies. The consequences on leukemic cell metabolism suggest pathways to be exploited for combination therapies in genomic-driven approaches.

PB1679

JAGGED-1 EXPRESSION IN MESENCHYMAL STROMAL CELLS HAS DISTINCT EFFECTS ON FLT3 MUTATED LEUKEMIA CELLS

M. Wobus*, M. Fusenig, K. Heidel, H. Altmann, M. Bornhäuser

Hematology/Oncology, Medical Faculty, University Hospital TU Dresden, Dresden, Germany

Background: Acute myeloid leukemia (AML) is a disease characterized by an increase in immature myeloid blasts in the bone marrow (BM) as a consequence of the loss of normal differentiation and uncontrolled proliferation of malignant hematopoietic stem and progenitor cells (HSPCs). As for normal HSPCs, the interaction with the surrounding BM microenvironment, *e.g.* with mesenchymal stromal cells (MSCs), mediated by cell surface proteins is important for leukemic cell fate and characteristics such as proliferation, survival and drug resistance. Amongst them, Notch pathways play an important role by regulating the crosstalk between leukemia cells and stromal microenvironment (Seke *et al.* 2012). Recently, we described the HSPC supportive effect of expression of Notch ligand Jagged-1 (Jag1) in MSCs (Duryagina *et al.* 2013).
Aims: Here, we aim to investigate specific effects of Jag1 expression in MSCs on leukemia cells.
Methods: MSCs were isolated by density gradient centrifugation and plastic adherence of mononuclear cells from healthy donors and AML patients (n=10) and were characterized by flow cytometry, Western blot and ELISA. The hTert immortalized MSC line SCP-1 with Jag1 over-expression or expression of dominant negative mastermind 1 (dnMAML1), in which Jag1 signaling of MSCs is blocked, has been described recently (Duryagina *et al.* 2013). AML cell lines MV4-11 (FLT-ITD positive) or OCI-AML3 (FLT3 wildtype) were co-cultured with the different SCP-1 cells and were analyzed by proliferation, adhesion and survival assays as well as by quantitative real-time PCR.
Results: MSCs of AML patients expressed common cell surface molecules, such as CD73, CD90, CD105, CD44, CD146 and CD166 but with higher variations than normal MSCs. Expression of the Notch ligand Jag1 was decreased in AML MSCs (detected in 3 out of 10 samples). The proliferation and adhesion capacity of MV4-11 cells was clearly decreased to about 35% on a SCP-1/Jag1 monolayer in comparison to wildtype and dnMAML1 cells. Addition of the g-secretase inhibitor DAPT partly rescued this effect confirming an involvement of Notch signaling. For OCI-AML3 cells no difference in proliferation and adhesion could be detected on the different SCP-1 layers. Treatment of MV4-11 cells with the tyrosine kinase inhibitor PKC412 (Midostaurin) or Ara-C increased the number of apoptotic and dead cells as detected by Annexin-V/PI staining in co-culture with SCP-1/Jag1 cells, suggesting that Jag1 over-expression can reverse the niche protective effect at least in part. Co-culture of MV4-11 cells on SCP-1/Jag1 cells caused a stronger induction of the Notch signaling pathway as shown by higher Hes-1 (20-fold) or Hey-1 (15-fold) mRNA expression levels than co-culture with SCP wildtype cells, whereas in OCI-AML3 this increase was significantly lower (2.5- and 1.5-fold, respectively). Whereas co-culture of AML cells caused inhibited secretion of SDF-1 by stromal cells, the co-culture of AML cells on SCP-1/Jag1 cells caused increased expression of CXCR4 mRNA in leukemia cells and accordingly 2- to 3-fold higher SDF-1 expression and secretion in the stromal cells in comparison to SCP-1 wildtype co-cultures. Again, these effects were much weaker in OCI-AML3 cells suggesting a role of FLT3 mutation.
Summary/Conclusion: In summary, we have demonstrated that the Jag1/Notch/Hes-Hey1 axis cause tumor inhibiting effects in FLT3 mutated AML cells. The different effects of Jag1 expression in MSCs on leukemia and normal hematopoietic cells may serve as prognostic marker and open a new therapeutic window.

PRO-APOPTOTIC EFFECTS OF A METABOLIC-ORIENTED TREATMENT IN ACUTE MYELOID LEUKEMIA

C. Banella[1,2,*], G. Guerrera[3], G. Catalano[1], D.F. Angelini[3], M. Divona[4], S. Travaglini[1], L. Battistini[3], M.T. Voso[1], F. Lo Coco[1,2], N.I. Noguera[1,2]

[1]Biomedicine and Prevention, Tor Vergata University, [2]Neuro-Oncohematology, [3]Neuroimmunology, Santa Lucia Foundation, [4]Policlinico Tor Vergata, Roma, Italy

Background: Alteration of metabolic pathways induced by tumors may represent a potential target for therapeutic intervention. Acute myeloid leukemia (AML) mainly affects elderly subjects unfit for intensive chemotherapy in most cases. While AMLs have been extensively characterized in terms of genetic profile, little is known about their metabolic profile. Several agents currently tested in clinical trials interfere with metabolic pathways, including ascorbic acid (ASC), which is a potent pro-oxidant when used at high doses, and the anti-diabetic drug Buformin®.
Aims: To characterize metabolic pathways in different AML subsets and to assess the efficacy of Buformin® in combination with ASC in these tumors.
Methods: Using RQ-PCR and western Blot we analyzed in primary blasts from 50 AML patiens the expression levels of 7 metabolic enzymes: *HK1*, *HK2*, *PKM2* and *LDH,* active in glycolysis control; *PDH* and *PDK,* involved in the synthesis of acetyl-CoA; and the regulators of fatty acid oxidation (FAO) CPTA1 and CT2. We measured oxygen consumption (OCR) and media acidification (ECAR) in cell cultures, by using the Seahorse XF Analyzer. We then studied the effects of metabolic-interference treating with Buformin® and ASC in different tumor cell lines: PR9 which derive from U937 cells and are PML-RARA-inducible, U937 transfected with the RUNX1-RUNX1T1 oncogene, OciAML3 AML2 cells, all AMLs and U87MG cells (glioblastoma). Buformin® was tested at 100 μM and 500 μM and ASC at 1mM concentrations. Apoptosis was assessed by flow cytometry using annexin and propidium-iodide staining.
Results: In patients with AML overexpression of *PDH* and *CT2* mRNA was detected in primary Acute Promyelocytic Leukemia (APL) cells, as compared to other AML subtypes. *CT2* overexpression was confirmed at the protein level and in PR9 cells. Concerning the metabolic activity, we demonstrated a decrease in glycolysis and a clear increase of mitochondrial respiration in the presence of PML-RARA, concomitant with the increase of *PDH* levels. In addition, increased levels of FAO were observed in association with *CT2* overexpression. Conversely, expression of the RUNX1-RUNX1T1 transcript in inducible systems resulted in induction of glycolysis and mitochondrial respiration. In the presence of PML/RARA, Buformin® blocked the mitochondrial respiration and the consequent production of ATP in the Krebs cycle. ASC, alone or in combination with Buformin®, produced a slight increase in the cellular glycolytic capacity. Conversely, in RUNX1-RUNX1T1-positive cells, Buformin® shut down respiration, while in combination with ASC markedly decreased cellular glycolytic capacity. Treatment of both cell lines with Buformin® and ASC, blocked FAO, indicating that the cytotoxic effect could be partly due to the depletion of energy content. The pro-apoptotic effect was confirmed in primary blasts from seven AML patients by flow cytometry (p=0.01, Figure 1). The series also included one case characterized by the rare PLZF-RARa transcript, which is ATRA and ATO resistant.

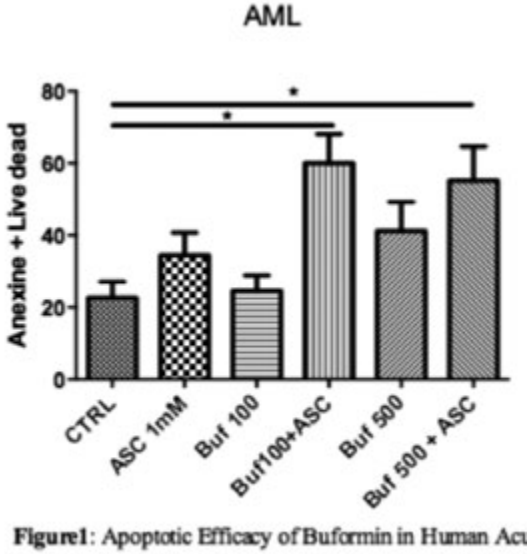

Figure1: Apoptotic Efficacy of Buformin in Human Acute Myeloid Leukemia Cells. Cooperation with Ascorbic Acid.

Figure 1.

Summary/Conclusion: Our data provide insights on metabolic changes in AML subtypes and indicates the possibility of a metabolically-oriented therapy in these diseases. Although further studies are required to confirm these observations, our data suggests that the Buformin®-ASC combination could be tested as an innovative and cost-effective therapeutic option in AML patients unfit for intensive chemotherapy.

PB1681

EXPLORATORY BIOMARKER ANALYSIS IN AML PATIENTS TREATED WITH ORAL SYK INHIBITOR ENTOSPLETINIB (GS-9973)

V. Munugalavadla[1,*], A. Joshi[1], A.R. Walker[2], T. Lin[3], M.D. Minden[4], H.E. Croswell[5], X. Tian[1], S.D. Patterson[1], A.V. Rao[1], Y. Pan[1]

[1]Gilead Sciences, Inc., Foster City, [2]The Ohio State University, Columbus, [3]University of Kansas Medical Center, Kansas City, United States, [4]Princess Margaret Cancer Centre, Toronto, Canada, [5]Bon Secours St. Francis Health System, Greenville, United States

Background: Acute myeloid leukemia (AML) is an aggressive hematopoietic malignancy characterized by diverse genetic and molecular abnormalities which contribute to poor response and survival rates. Spleen tyrosine kinase (SYK) signaling induces cell survival and proliferation by activating multiple pathways including chemokine regulation. Entospletinib (ENTO), an oral selective SYK inhibitor, is currently in clinical trials in AML. Previously we have shown that ENTO treatment inhibited BCR-mediated chemokines such as CCL3 and CCL4 in CLL patients (Sharman J *et al.*, 2015). This retrospective longitudinal systemic biomarker analysis aims to understand the effects of SYK inhibition by ENTO during lead-in monotherapy and induction chemotherapy (IC) in untreated AML patients (NCT02343939).
Aims: (1) Explore the pharmacodynamic (PD) effects of ENTO during monotherapy lead-in on systemic biomarkers related to SYK and or AML disease (2) Correlate baseline biomarkers with complete remission (CR) rates and various molecularly defined AML sub-groups [*NPM1*, *FLT3-ITD/TKD* and *KMT2A/*mixed lineage leukemia gene rearrangements (*MLL-R*)].
Methods: Longitudinal plasma samples [baseline, 6hr post dose on day 1, day 8, and day 14 during ENTO monotherapy and post induction chemotherapy] from AML patients treated with ENTO monotherapy for up to 14 days and subsequently in combination with induction chemotherapy (7+3; cytarabine 100mg/m^2 for 7 days plus daunorubicin 60mg/m^2 for 3 days) were analyzed. A panel of 64 cytokines/chemokines including markers known to be regulated by SYK and key markers implicated in driving AML disease was tested. We utilized validated electrochemiluminescence multiplex immune assays from Meso Scale Discovery (MSD). Biomarker fold changes at each time point were compared to baseline using a Wilcoxon signed rank test. Correlations of these cytokines/chemokines levels at baseline with response rates and with various molecular subgroups were assessed using Wilcoxon rank-sum test.
Results: Chemokines such as CCL3, CCL4, CCL17 and CXCL-10 known to be regulated by SYK were significantly decreased from baseline after ENTO monotherapy. Additionally, key markers that have a role in driving AML disease such as IL-12p40, IL-1RA and TNFα were also significantly reduced. Heatmap of changes over the time in various biomarkers are presented in Figure 1A. Higher baseline CCL1 were observed in patients that achieved CR compared to non-CR (Figure 1 B; p=0.027). Further molecular sub-set analysis showed that patients with *NPM1* mutation and with *FLT3-ITD/TKD* that were enriched in CR had high baseline CCL1 compared to wild type *NPM1* and *FLT3* patients. Baseline CCL1 levels were not significantly different between *MLL-R* patients and non-*MLL-R* patients even though most of *MLL-R* patients achieved CR suggesting underlying biology could be different in these sub-set of patients. Of note, in this study (NCT02343939) no ENTO exposure *versus* best overall response relationship was observed. Exploratory baseline *versus* post induction chemotherapy analysis is ongoing and updated results will be presented.

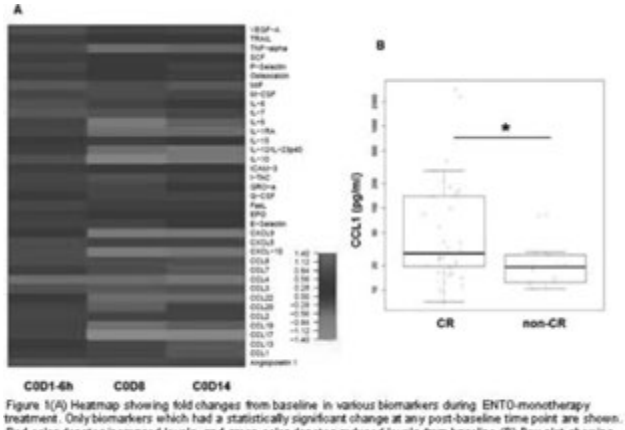

Figure 1(A) Heatmap showing fold changes from baseline in various biomarkers during ENTO-monotherapy treatment. Only biomarkers which had a statistically significant change at any post-baseline time point are shown. Red color denotes increased levels, and green color denotes reduced levels from baseline (B) Box plot showing baseline CCL1 levels in subjects that achieved complete remission (CR) compared with those that did not achieve complete remission (non-CR) in AML patients (NCT02343939); * Wilcoxon rank sum test p=0.027.

Figure 1.

Summary/Conclusion: This is the first study that has demonstrated a PD effect of the SYK inhibitor Entospletinib during lead-in monotherapy in AML patients. In addition, baseline biomarker CCL-1 was observed to be associated with clinical response. Conclusions from this study are limited given this exploratory analysis in this small study and considering that no adjustments for multiple testing were applied to *p*-values, hence, all observations should be considered hypothesis generating.

PB1682

SENSITIVE AND EARLY DETECTION OF THE PML-A216V MUTATION BY DROPLET DIGITAL PCR IN ARSENIC TRIOXIDE RESISTANT ACUTE PROMYELOCYTIC LEUKEMIA

V. Alfonso[1,*], L. Iaccarino[1], T. Ottone[1,2], L. Cicconi[1], S. Lavorgna[1], M. Divona[1], R. Cairoli[3], A. Cristiano[1], C. Ciardi[1], P. Chiusolo[4], A. Venditti[1], W. Arcese[1], M.T. Voso[1], F. Lo-Coco[1]

Cuore, Rome, Italy

Background: The use of ATRA combined with chemotherapy (CHT) and/or arsenic trioxide (ATO) can achieve long-term remission in the vast majority of patients with newly diagnosed APL. Despite this therapeutic success, 5-10% patients still relapse after modern treatment. Up to 30% of relapsed/refractory patients harbor point mutations within the ATO-binding domain (B2) of the PML moiety of the PML/RARA hybrid. These alterations affect the binding of ATO to the oncoprotein and thus impair PML/RARA degradation and clinical response to this agent. The most common mutation detected in APL refractory to ATO is the A216V, which is located within the PML-B2 domain.
Aims: In the present study, we developed and tested a droplet digital PCR (ddPCR) assay for the sensitive detection of *PML*-A216V mutation in relapsed APL patients as a tool to early predict ATO-resistance.
Methods: A total of 13 patients who relapsed after ATO treatment were analyzed. Table 1 shows the main patient characteristics at the time of APL diagnosis. Initial treatment included ATRA/CHT in 10 and ATO/ATRA in 3 cases. Eleven patients in the series underwent multiple relapses. Mutational analysis was performed at the time of first relapse in the 3 patients treated with front-line ATO and in ≥2nd relapse in patients receiving ATO as salvage treatment. Mutational analysis of *PML*-A216V by ddPCR assay (BioRad), was performed in duplicate, using 50 ng of DNA for each sample. The limit of detection (LOD) of ddPCR assay was determined by diluting mutant DNA in the DNA sample derived from a healthy donor at the following ratios: 1:10, 1:100, 1:250 and 1:500. The threshold for positive amplification was established within each reaction based on the results of *PML*-A216V negative template controls. The ddPCR assay was initially performed on DNA samples collected at the time of relapse where a high *PML/RARA* copy number had been detected by conventional RQ-PCR. We then investigated the mutation dynamics by backtracking the identified mutation in samples collected for routine PML/RARA monitoring prior to relapse. To confirm and compare the results obtained by ddPCR, all positive samples were also analyzed by Sanger sequencing.

Table 1.

Table 1. Clinical and biological characteristic of APL patients.

UPN	Age/Sex	Sono risk	PML/RARA isoform	First-line treatment	CR1 duration	Relapses (n)	Timing of ATO treatment	Response to ATO	PML mutational status by ddPCR
1	54/M	Standard	BCR1	ATRA-ATO	3 months	2	Front-line	mCR*	PML wt
2	32/M	Intermediate	BCR1	ATRA-ATO	23 months	1	Front-line	mCR*	PML wt
3	77/M	Intermediate	BCR3	ATRA-ATO	18 months	1	Front-line	mCR*	PML wt
4	29/F	Intermediate	BCR1	ATRA-CHT	35 months	4	Salvage	Refractory	PML A216V
5	77/M	Intermediate	BCR1	ATRA-CHT	17 months	2	Salvage	Refractory	PML A216V
6	40/F	Intermediate	BCR2	ATRA-CHT	3 months	1	Salvage	Refractory	PML A216V
7	68/M	Intermediate	BCR1	ATRA-CHT	24 months	2	Salvage	Refractory	PML A216V
8	38/M	Standard	BCR3	ATRA-CHT	8 months	2	Salvage	Refractory	PML wt

10	42/F	Low	BCR3	ATRA-CHT	12 months	2	Salvage	mCR*	PML A216V
11	61/M	Intermediate	BCR3	ATRA-CHT	30 months	3	Salvage	Refractory	PML wt
12	66/F	Intermediate	BCR1	ATRA-CHT	26 months	3	Salvage	Refractory	PML wt
13	32/F	Standard	BCR1	ATRA-CHT	36 months	3	Salvage	mCR*	PML wt

*mCR=molecular Complete Remission

Results: The ddPCR test showed high reproducibility and sensitivity and was able to detect up to 0.4% *PML*-A216V-mutant allele fraction. After assessing the false positive rate (FPR), samples were considered positive if the mutation rate had ≥3 positive droplets above the threshold of the negative template controls. The A216V mutation was detected by ddPCR in 5/13 patients (38%) who relapsed after ATO. Sanger sequencing allowed to identify the *PML*-A216V mutation in 4/5 cases. The ddPCR assay carried out in follow-up DNAs of mutated patients (total of 44 samples, median 3 per patient, range:1-22), revealed the presence of *PML*-A216V mutation in 17 samples. Of these, 3 were collected in overt relapse while 14 were taken at molecular relapse in patients showing low *PML/RARA* transcript levels. Sanger sequencing confirmed the mutation in only 4/17 samples. In 3 mutated patients for whom several sequential samples were available, a positive-ddPCR test anticipated a positive Sanger sequencing result by 3, 4 and 24 months, respectively.
Summary/Conclusion: Our data show that a ddPCR assay can be efficiently employed in the screening of *PML*-A216V mutation in APL and is able to identify mutant cases earlier in the disease course as compared to conventional sequencing. This sensitive method may help to identify ATO-resistant APL patients who are candidate to alternative treatment strategies.

GENE EXPRESSION PROFILING REVEALS A THREE-GENE ANTIAPOPTOTIC SIGNATURE USEFUL TO SWITCH-OFF ANTIAPOPTOTIC STIMULI IN ACUTE MYELOID LEUKEMIA

J. Nanni[1,*], G. Simonetti[1], G. Marconi[1], M.C. Fontana[1], S. Bruno[1], C. Papayannidis[1], M. Abbenante[1], S. De Polo[1], C. Sartor[1], S. Parisi[1], S. Paolini[1], A. Curti[1], M. Cavo[1], G. Martinelli[2]

[1]Department of Experimental, Diagnostic and Specialty Medicine, University of Bologna, Institute of Hematology "L. e A. Seràgnoli", bologna, [2]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) s.r.l IRCCS, Meldola, Italy

Background: Apoptotic regulation involves several actors which can have a positive and negative effect and may represent a target for personalized therapy. Nowadays, BCL-2 inhibitors have successfully passed preliminary phases of clinical experimentation, however the involvement of other essential proteins could represent a resistance mechanism to BCL-2 inhibitors and reveal novel therapeutic target in acute myeloid leukemia (AML).
Aims: Our study aim to investigate the expression of anti-apoptotic genes in AML patients and to unravel if these differential expressions are associated to genomic alterations.
Methods: We performed Human Transcriptome Array 2.0 (Affymetrix) and SNP 6.0 or Cytoscan HD Array (Affymetrix) in cohorts of 59 and 270 newly diagnosed AML, respectively. K-means clustering has been used to categorize patients in different cluster of expression. A pool of 7 healthy donors was used to normalize expression data. Survival analysises were conducted with Kaplan-Meyer method and differences in survival were assessed with Log-Rank test. Fisher exact test has been performed to evaluate significant associations on Copy Numeber Data.

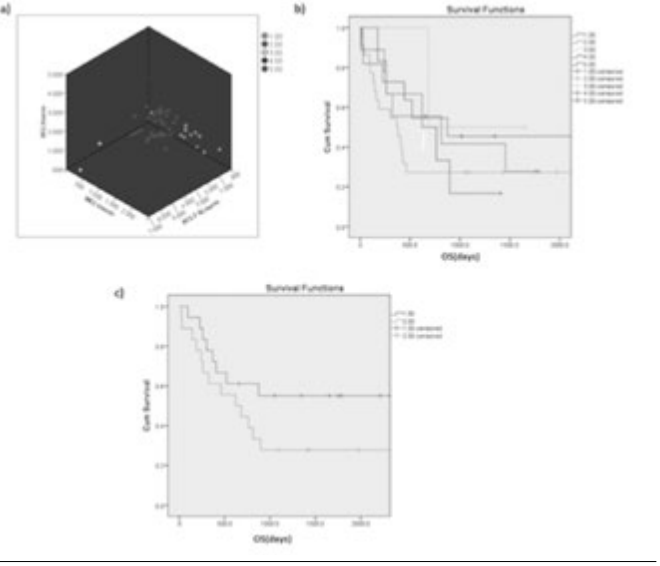

Figure 1.

Results: *BCL-2*, *MCL-1* and *BCL2L1* gene expression values in 59 AML patients allowed us to establish 5 clusters (Fig. 1a): cluster 1 with the overexpression of *MCL-1*, cluster 2 with low expression of all analyzed genes; cluster 3 with overexpression of *BCL2L1*, cluster 4 with overexpression of *BCL-2* and cluster 5 with high values of expression of all 3 genes. Clusters

2 and 5 included the majority of patients (40/59, 68%). Furthermore, the 3-D Scatter Plot (Fig. 1a) showed that the patients out of the central cloud (Clusters 2-5) always presented an overexpression of one out of the three anti-apoptotic genes. Moreover, when *BCL-2* level is low (Cluster 1-2-3), *MCL-1* or *BCL2L1* levels are high, respectively. In term of overall survival (OS), there were no statistically significant difference between Cluster 1-3-4, where one different anti-apoptotic gene is always overexpressed (Fig. 1b). Finally, analyzing the impact of *BCL-2* expression on OS in a cohort of 36 young patients treated with chemotherapy, those with high expression of *BCL2* gene had worse outcome (Fig. 1c, p=0.07). Subsequently, we screened a cohort of 270 AML patients for genomic copy number alterations by SNP array. We could not find significant CNA that could be rationally related to *BCL-2*, *MCL-1* and *BCL2L1* expression: *BCL2* was lost in 3.7% and gained 1.1% of cases; *MCL-1* was lost in 1.1% and gained in 0.37% of cases; and *BCL2L1* was lost 0.37% and gained in 1.85% of patients.

Summary/Conclusion: *BCL-2*, *MCL-1* and *BCL2L1* expressions are quite balanced in AML patients. One out of the three genes is often overexpressed, confirming the key role of anti-apoptotic genes in leukemogenesis. Even though *BCL-2* expression influences patients chemosensitivity, *MCL-1* and *BCL2L1* overexpression has been documented when *BCL-2* is normally or downregulated. The overexpression of these genes can not be explained only by genomic aberrations. Finally, a combined approach should be realized to switch-off leukemic anti-apoptotic mechanisms: gene expression profile could provide a synthetic lethal instrument to choose the proper BH3-mimetic drug or combination. Further studies are needed to confirm the post-traductional context and unveil other characters of this pathway regolation.

THE DNA DAMAGE REPAIR PATHWAY IS ALTERED IN POOR PROGNOSIS ACUTE MYELOID LEUKEMIA PATIENTS AND IDENTIFIES POTENTIAL TARGETS FOR SYNTHETIC LETHAL THERAPIES

A. Padella[1,*], G. Simonetti[1], M.C. Fontana[1], G. Marconi[1], A. Ferrari[1], C. Papayannidis[1], S. Bruno[1], E. Fonzi[1], M. Pazzaglia[1], E. Ottaviani[1], M. Cavo[1], S. Soverini[1], G. Martinelli[2]

[1]Department of Experimental, Diagnostic and Specialty Medicine, Seragnoli institute, Bologna, [2]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST) Srl-IRCCS, Melodola (FC), Italy

Background: Partner and localizer of BRCA2 (*PALB2*) plays a key role in the DNA damage repair (DDR) and genomic alterations of DDR genes rarely occur in acute myeloid leukemia (AML), while their deregulation at transcriptional level is a known mechanism exploited by leukemic cells in order to sustain the high genetic instability and to continue proliferation.

Aims: We aimed to characterize the role of *PALB2* in AML by investigating its genomic alterations and its expression levels, in order to evaluate its potentiality as target of therapies based on a synthetic lethal approach.

Methods: We genotyped 270 AML samples by Single Nucleotide Polymorphism array (SNP 6.0 and Cytoscan HD, Affymetrix). We performed Whole Exome Sequencing (WES, Illumina) of 69 cases to detect single nucleotide variants (MuTect and Varscan 2.0). Gene expression profiling (GEP, Affymetrix) was performed on bone marrow cells of 7 healthy donors (HD) and 60 AML patients. K-means clustering of patients according to the expression of *PALB2* was performed.

Results: AML patients carried copy number alterations (CNA) in genes involved in the DDR pathway including *PALB2*, *BRCA1*, *BRCA2*, *FANCA* and *RAD50*. Among them, 11 patients (4%) carried a CN loss of *PALB2* with a minimal common region of 6.6 Kb, including ex 11-12 encoding for domain of interaction with other DDR related genes. Notably, these patients were also characterized by the co-occurrence of losses of 5q, 17q11, 16p13-p12 and gain of 21q22. Biologically relevant genes targeted by CNAs in PALB2-loss patients were *TP53*, *NF1*, *BRCA1*, *STAT3*, *FANCA*, *CREBBP*, *XPO* and *USP34*. Enrichment analysis of differentially altered genes (q<.001) revealed that GO biological processes affected by CNAs included protein folding, apoptotis, mitotic cell cycle, metaphase/anaphase transition, nucleic acid phosphodiester bond hydrolysis, double-strand break repair (p<1e-04). *PALB2* was not mutated in our WES dataset. However, DDR genes such as *TP53*, *BRCA1*, *BRCA2*, *CHEK2*, *FANCE* were found mutated at least once. Moreover, *PALB2* loss significantly associated with *TP53* mutations (p=0.015) while *KRAS*, *IDH1/2*, *TET2* mutations were mutually exclusive. Transcriptional analysis revealed variable *PALB2* levels in AML patients (range 52.90-244.37) and its median expression was higher compared with HD (129.26 *vs* 67.85, respectively; p=.019). We clustered patients according to *PALB2* expression and defined 2 clusters: H and L with high and low expression levels of *PALB2*, respectively (cluster centers 158.86 and 105.41, respectively). Enrichment analysis of differentially expressed genes revealed deregulations of the following GO pathways: mitochondrial translational, regulation of cell proliferation, negative regulation of myeloid cell differentiation and G1/S transition of mitotic cell cycle (p<.013).

Summary/Conclusion: We dissected the molecular and transcriptional landscape of AML and we identified alterations in *PALB2* and the DDR pathway in a small subgroup of patients. Our data open a new scenario in which *PALB2* may drive dependencies to be exploited by targeted therapies in AML: breast cancer patients carrying mutations in *PALB2* and *BRCA1/2* are candidate for PARP inhibitors treatment, while few clinical trials are available in AML. Therefore, we identified a group of AML patients which may benefit of personalized therapies based on synthetic lethal approaches targeting the DDR pathway.

PB1685

ESTIMATING THE OPTIMAL THRESHOLD OF BAALC AND ERG AS PREDICTIVE BIOMARKERS IN ACUTE MYELOID LEUKEMIA

S.K. Hasan[1,*], N. Patkar[2], D. Vishwakarma[1], D. Rajamanickam[1], A. Bhattacharjee[3], A. Gokarn[1], S. Punatar[1], A. Bonda[1], L. Nayak[1], P. Tembhare[2], S. Kannan[4], B. Bagal[1], H. Jain[1], P. Amare[5], H. Menon[1], M. Sengar[1], S. Gujral[2], P. Subramanian[2], N. Khattry[1]

[1]Adult Hematolymphoid Disease Management Group, [2]Hematopathology Laboratory, Tata Memorial Centre, Mumbai, [3]Centre for Cancer Epidemiology, [4]Biostatistics, Advanced Centre For Treatment Research and Education in Cancer Mumbai, Navi Mumbai, [5]Cytogenetics Laboratory, Tata Memorial Centre, Mumbai, India

Background: The high expression of brain and acute leukemia, cytoplasmic (*BAALC)* and *ETS-related gene (ERG)* has been associated with poor prognosis in acute myeloid leukemia (AML) but due to limited prospective studies, their role as prognostic factors is still unclear. We had presented the *BAALC* & *ERG* expression data and its impact on survival during the ASH 2017 meeting at San Diego. In that study, the median value was taken as a cut-off to distinguish between high & low *BAALC/ERG* expressers. So far, there are no standard methods or tools to decide the optimal cut-off points. In this analysis of the same cohort of patients, we generated threshold values for *BAALC* & *ERG* cut-off points through P-chain procedure (Bhattacharjee *et al.* 2017). In brief, *BAALC* & *ERG* expression values were measured as continuous variable at baseline, post-induction and post-consolidation blood/marrow samples. Further, lists of p-values were generated from arbitrarily defined threshold values of *BAALC* & *ERG*. The lowest p-value was defined as maximum survival difference among these patients to decide the cut-off point for threshold values of *BAALC* & *ERG*.

Aims: To determine the optimal threshold values of *BAALC* & *ERG* expression as a cut-off point to predict the survival outcome.

Methods: All patients included in this prospective study (N=149) between March 2012 & February 2015 underwent following investigations: (i) Cytogenetic analyses- by standard techniques of chromosome banding & FISH (ii) Mutation profiling of *NPM1*, *FLT3*-ITD and *CEBPA* by capillary electrophoresis & direct DNA sequencing. Long-range PCR was done to establish *MLL*-PTD (iii) *BAALC* & *ERG* expressions by quantitative real-time PCR assays. Patients received standard induction chemotherapy with daunorubicin 60mg/m^2 for 3 days and cytosine arabinoside 100 mg/m^2 for 7 days. Marrow was done 21-28 days after start of chemotherapy. If marrow was in remission, then patients received 3 courses of consolidation therapy with 12-18gm/m^2 of cytosine arabinoside (HiDAC). The statistical analysis was done using R 3.4.0 version.

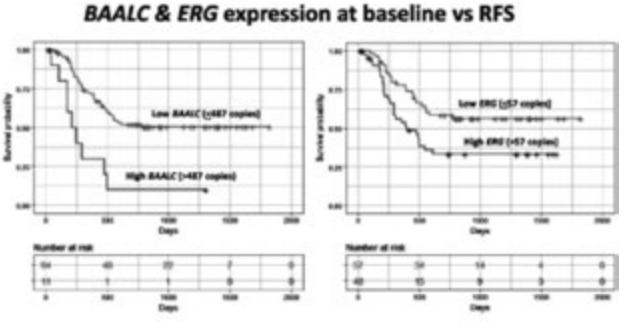

Figure 1.

Results: A total of 149 patients were accrued. Of 149 patients, 105 achieved CR after 1 or 2 cycles of chemotherapy. Twenty-seven patients were refractory of which 18 were lost to follow up and hence excluded from OS analysis. Seventeen patients died during induction. The follow-up samples included post induction (N=120) and post-consolidation (N=95) bone marrow. The OS of 132 patients was 36.5% at 2 years. The OS & RFS of 105 patients who achieved CR was 54% and 43.8% respectively. The threshold value (487 *BAALC* copies*/ABL [on OS and RFS]*, 34 *ERG* copies*/ABL[on OS] and* 57 *ERG* copies*/ABL[on RFS]*) was used to distinguish high expressers from low expressers. Initially, the baseline, post induction and post-consolidation expression values of *BAALC* & *ERG* were observed for their influence on OS & RFS using univariate Cox proportional hazards analyses & results are reported in Table 1. The data revealed that higher *BAALC* & *ERG* expression values were significantly hazardous for OS & RFS. Furthermore, threshold values of *BAALC* & *ERG* at baseline were calculated and results are reported in Table 2. The RFS of high *BAALC vs* low *BAALC* expressers at 2 years was 9% *vs* 51% (p=0.059), while RFS of high *ERG vs* low *ERG* expressers at 2 years was 31% *vs* 59% (p=0.013) (Figure 1).

Table 1.

Table1: Analysis to assess the impact of *BAALC* and *ERG* baseline, post induction and post consolidation expression on OS and RFS

Measurement	Parameter	Number of Patients	Number of Events	HR	se(coef)	95% CI	P-value
Overall Survival	ERG_Baseline	132	25	1.79	0.24	[1.11,2.87]	0.015
	ERG_PostInduction	120	18	2.11	0.25	[1.28,3.48]	0.003
	ERG_PostConsolidation	95	8	2.09	0.46	[0.84,5.20]	0.110
	BAALC_Baseline	132	25	1.07	0.17	[0.75,1.53]	0.676
	BAALC_PostInduction	120	18	1.66	0.19	[1.13,2.43]	0.009
	BAALC_PostConsolidation	95	8	1.75	0.23	[1.10,2.78]	0.016
Relapse Free Survival	ERG_Baseline	105	50	1.37	0.11	[1.11,1.74]	0.004
	ERG_PostInduction	98	50	1.07	0.10	[0.86,1.31]	0.567
	ERG_PostConsolidation	88	45	1.83	0.16	[1.30,2.51]	0.000
	BAALC_Baseline	105	50	1.62	0.09	[1.34,1.95]	0.000
	BAALC_PostInduction	98	50	1.51	0.09	[1.23,1.75]	0.000
	BAALC_PostConsolidation	88	45	1.61	0.08	[1.34,1.91]	0.000

Table 2.

Table2: Analysis to assess the impact of *BAALC* and *ERG* baseline expression on OS and RFS based on threshold values

Gene expression	Parameters	Parameter estimates	Error	Hazard ratio	P-value
BAALC baseline ≤ 487 .04 BAALC baseline > 487 .04	OS	0.917	0.505	2.503	0.0687
BAALC baseline ≤ 487 .04 BAALC baseline > 487 .04	RFS	0.828	0.431	2.291	0.0598
ERG baseline ≤ 34 .2 ERG baseline > 34 .2	OS	1.303	0.372	3.682	0.000
ERG baseline ≤ 57 .43 ERG baseline > 57 .43	RFS	0.705	0.284	2.204	0.013

Summary/Conclusion: This study established the optimal threshold values of *BAALC* & *ERG* expression as cut-off points to predict the outcome. The data suggest that high *BAALC* & *ERG* expression adversely affects prognosis of AML patients.

PB1686

THE ROLE OF DNA REPAIR MECHANISMS IN ACUTE MYELOID LEUKAEMIA

C. Crean*, K. Savage, K. Mills

Centre for Cancer Research, Queens University Belfast, Belfast, United Kingdom

Background: The therapeutic landscape for AML has changed little over the past four decades. Cytarabine, first approved in 1969, is still a standard of care treatment option for AML despite little improvement in survival rates over time. Whilst AML is a disease which can occur at any age, it predominantly affects people over the age of 65. With an increasing elderly population, the rate of incidence of AML is set to increase. Additionally, although some patients do respond to Cytarabine treatment, there is no signature or test available to determine which patients will, or will not, benefit from this type of treatment. A DNA Damage Repair Deficiency (DDRD) score was previously developed to identify breast cancers with an intrinsic DNA double strand break (DSB) repair deficiency and therefore may respond positively to DNA damaging chemotherapeutic agents such as cyclophosphamide. This assay can be adapted to different cancer types including AML.
Aims: The objective of this study was to examine if the DDRD assay can be applied to AML samples as a potential biomarker of response and/or survival.
Methods: To test the effectiveness of DDRD score as a biomarker the DDRD calculation was applied to RNA expression data from 645 AML patients. The score was also determined for a panel AML cell lines. Cell lines defined as DDRD positive or negative were tested for sensitivity to different DNA damaging agents using clonogenic survival assays. The DNA repair capacity of these cell lines was also examined by assessing their ability to repair ionising radiation induced DSBs.
Results: Approximately 39% of the patients scored as DDRD positive. This did not significantly correlate with any risk group, cytogenetic abnormality or mutation such as FLT3 or NPM1. Survival analysis showed that the DDRD positive patients had a significantly worse survival than the DDRD negative patients (10-year survival 27% in DDRD positive patients compared to 42% in DDRD negative (p-value=0.00047)) despite the prediction of responding better to DNA damaging agents as seen in the breast cancer studies. The response of the cell lines to the DNA damaging agents corresponded with the patient data with DDRD positive cell lines showing less sensitivity to cytarabine as DDRD negative cell lines. The foci analysis from the IR treated cells also showed that the DDRD positive cell lines do not repair DSBs as effectively as the DDRD negative cell lines.
Summary/Conclusion: These results suggest that determining the DDRD score could effectively be used to determine which patients would benefit from treatment with DNA damaging agents. Furthermore, the poor survival rate of the DDRD positive patients indicates that cytarabine is not the optimal treatment option for these. Further analysis of this unresponsive AML sub-group could highlight therapeutic pathways to target either as single agents or in combinations with for example PARP inhibitors.

PB1687

THE ROLE OF S100A4 IN ACUTE MYELOID LEUKEMIA

B. Alanazi[1,*], A. Pierce[2], A.D. Whetton[2], S. Knapper[1], C.R. Munje[3], R. Darley[1], A. Tonks[1]

[1]Department of Haematology, School of Medicine, Cardiff University, Cardiff, [2]Faculty of Medical and Human Sciences,Institute of Cancer Sciences, The University of Manchester, Manchester, [3]Paul O'Gorman Leukaemia Research Centre, University of Glasgow, Glasgow, United Kingdom

Background: Acute myeloid leukemia (AML) is a disorder arising from developmental arrest of cells of the myeloid lineage. To understand how regulators of transcription mediate this block, we previously analyzed the nuclear proteome of AML blasts against developmentally matched HSPCs and found nuclear mislocalization and differential expression of S100A4. Cytosolic overexpression of this calcium binding protein has been implicated in solid tumours and is associated with poor clinical outcomes; however, little is known about the role of aberrant nuclear expression of S100A4 in AML.
Aims: (i) To validate the overexpression of S100A4 in AML patients and cell lines; (ii) To determine the effects of overexpressed S100A4 on haematopoietic growth and development using normal human $CD34^+$ cells; (iii) To determine whether AML cell lines are dependent on S100A4 overexpression.
Methods: We analysed AML patient samples (n= 24) for S100A4 expression and subcellular localisation by western blot using normal $CD34^+$ cells as controls. Lentiviral vectors containing Nuclear Localisation Signals (NLS) were used to overexpress S100A4 into the nucleus of normal HPSCs and AML cell lines. shRNA was used to knock down S100A4 in normal HPSCs and in AML cell lines. Effects on growth and haematopoietic development were analysed by multiparameter flow cytometry.
Results: To confirm our initial studies, we analyzed a second cohort of AML patient blasts and identified S100A4 to be mislocalized to the nucleus in ~83% of AML cases (20/24). Interestingly, S100A4 protein was not expressed in the nucleus of normal HSPC or differentiated precursors in myeloid lineage (monocytes, erythrocytes, and granulocytes) throughout development. To determine the effect of nuclear-targeted S100A4 overexpression, we infected $CD34^+$ cells with lentivirus encoding nuclear-targeted S100A4. Whilst we could over-express S100A4 in the nucleus of some leukemic cell lines, we could not stably express it in HSPCs. We found that nuclear expression of S100A4 increased cell proliferation in TF-1 compared to uninfected controls. Conversely, knockdown of S100A4 in cell lines with elevated S100A4 expression using shRNA, induced cell death in THP-1, OCI-2 and TF-1.
Summary/Conclusion: We found that S100A4 is over-expressed and mislocalized to the nucleus in AML blasts. Whilst normal HSPCs express this protein in the cytosol of some myeloid differentiated lineages, they do not tolerate over-expression of this protein in the nucleus. In the context of transformed cells, S100A4 promotes proliferation and is essential for AML cell survival. These data suggest that S100A4 could be a target for therapy for AML.

PB1688

MOLECULAR CHARACTERIZATION OF PEDIATRIC ACUTE MYELOID LEUKEMIA: RESULTS OF A PROSPECTIVE MULTICENTRIC STUDY IN RUSSIA

A. Panfyorova*, M. Gaskova, N. Timofeeva, O. Soldatkina, A. Kazakova, I. Kalinina, G. Novichkova, M. Maschan, A. Maschan, Y. Olshanskaya

Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation

Background: The genetic characterization of pediatric acute myeloid leukemia (AML) is an important outcome predictor. Genomic profiling studies have dramatically advanced our understanding of the origin, progression and clonal evolution of AML. High-Throughput Sequencing (HTS) provides a unique insight into mechanisms of disease initiation, risk stratification and treatment and multi-gene mutation panel is a part of diagnostic routine testing by now.
Aims: To perform expanded prospective molecular diagnosis in children with AML mainly concerning comprehensive risk assessment and stratification and to improve our understanding of mutational and clonal complexity in each patient because of the morphological and molecular heterogeneity of AML.
Methods: Genetic analyses of bone marrow (BM) samples from pediatric patients with newly diagnosed *de novo* AML recruited into the Russian National Prospective AML Study between September 2016 and February 2018 were performed by a combination of fragment analysis, Sanger sequencing for genes involved in risk stratification, and HTS with Human Myeloid Neoplasms Panel (HMNP) (Qiagen, Germany) for analysis of 141 genes most commonly mutated in myeloid neoplasm. Library was constructed for sequencing on a MiSeq using v3 chemistry with 2x150 bp read length.
Results: Diagnostic samples from 146 (75 male and 71 female) pediatric patients with *de novo* AML were analyzed. Age at diagnosis ranged from 0 to 17,6 years (median 6,6). An average depth of 978x was achieved. The total read fragments number was about 2 358 019 generated reads per sample with primer found on-target ~ 95.7%. Coding and splice site regions of *FLT3*, *NPM1*, *KIT*, *CEBPA* genes were fully covered, *GATA1* gene had almost full coverage with the exception of exon 4. All SNV mutations in risk stratification genes were confirmed by Sanger sequencing. However indel variants such as *FLT3*-ITD (18 cases, size range-from 20 to 115) we accurately identified in all cases just only by fragment analysis, HTS analysis algorithms could only find the smallest of them-20 and 22 bp. Overall, 15% (22/146) of analyzed patients had normal karyotype, they showed molecular mutations in risk-stratification genes: 1(4,6%) patient had isolated *FLT3*-ITD, 4 (18%) had isolated *NPM1*mut, in 5 (22,7%) cases combination of *NPM1*mut+*FLT3*mut was observed and only 1 (4,6%) patient had bi*CEBPA*. The numerous mutations were identified in additional genes: *RUNX1, NRAS, KRAS, PTPN11, WT1, IDH1, IDH2, DNMT3A, ASXL1, ASXL2, STAG2.* A highest mutational rate and their variable cooperation were observed in patients with normal karyotype and t(8;21). In 16 patients with t(8;21) *KIT* mutations were found in 10 (62,5%). AML with t(8;21) displayed also elevated mutational diversity: *NRAS, RUNX1, ASXL2, EZH2, STAG2, NOTCH1, CSF3R, KDM6A, TP53, RAD21, JAK3, U2AF2.*
Summary/Conclusion: Our results reflect the profile of pediatric AML cases in Russia. In our study the identification of subgroups defined by molecular aberrations, according to national diagnostic recommendations for specific treatment and assessment of molecular heterogeneity were performed. There were significant differences in gene mutations among morphological, cytogenetic and age groups. The nonrandom mutational cooperations were observed. Identification of genetic subgroups is important for the molecular epidemiology and biology of AML worldwide.

PB1689

ADAM28 AGGRAVATES THE LEUKEMIA BURDEN IN A MICE MODEL AND PREDICTED A HIGH RISK OF RELAPSE IN FAVORABLE-RISK AML PATIENTS

J.-M. Zhang[1,2,3,*], C.-C. Wang[1,2,3], Q. Jiang[1,2,3], H.-X. Fu[1,2,3], Q.-M. Wang[1,2,3], X.-L. Zhu[1,2,3], H. Jiang[1,2,3], Y. Wang[1,2,3], M. Lv[1,2,3], Y.-J. Chang[1,2,3], L.-P. Xu[1,2,3], K.-Y. Liu[1,2,3], X.-J. Huang[1,2,3], X.-H. Zhang[1,2,3]

[1]Peking University Institute of Hematology, Peking University People's Hospital, [2]Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, [3]Collaborative Innovation Center of Hematology, Peking University, Beijing, China

Background: We have reported that ADAM28 promoted the invasion and survival of leukemic cells; however, the precise prognostic relevance between ADAM28 and acute myeloid leukemia (AML) remain unknown.
Aims: To compare the outcome of AML depending on the expression of ADAM28.
Methods: A well-established NOD/SCID xenotransplantation model was used to test the effect of ADAM28 on the AML burden. Bone marrow samples were obtained from adults with AML (N=107) and normal individuals (N=24) recruited at the Hematology Department of Peking University People's Hospital between May 2013 and May 2014, among which 32 were part of the test group and 75 were prospectively enrolled to the validation group.
Results: The relative expression level of ADAM28 in the leukemic cells of the testing group was significantly higher than that in the control BM cells (0.98± 0.09 *vs* 0.49±0.04; p<0.001). Furthermore, the ADAM28 level in the CSF of patients with CNSL was significantly higher than that without CNSL (2.87±0.81 *vs* 0.50±0.08, p<0.0001). In the intrafemoral xenotransplantation experiments, peripheral leukocyte counts were significantly lower in mice receiving ADAM28-knock out (KO) cells compared with those in mice with control cells. A Kaplan-Meier plot demonstrates that mice bearing ADAM28-KO cells survived longer compared with control mice (P= 0.017). Slighter splenomegaly was observed in mice with ADAM28-KO cells. Additionally, knock out of ADAM28 decreases the incidence of CNS infiltration. In the *in vitro* experiment, the increased expression of ADAM28 led to more IGFBP-3 degradation and IGF-I-induced cell proliferation. To validate the effect of ADAM28 protein level on the prognosis of AML patients, we extended ADAM28 expression level detection to a validation group of 75 patients with AML. The ADAM28 expression level of the validation group in the bone marrow and CSF between patients with or without CR had the same trend as the testing group. Prognostic analysis revealed that in the enrolled 87 patients (patients with APL were excluded), the CIR and EFS was significantly higher in the ADAM28 high expression group (p=0.003, 0.021 and 0.017 respectively). However, the prognostic analysis in patients with M3 did not differ significantly. Notably, when separately analyzing the impact of the ADAM28 expression level on prognosis within clinically defined risk groups, patients with high ADAM28 expression levels had a significantly higher CIR and worse EFS in the favorable-risk group, and a significantly higher CIR in the intermediate-risk group, but this discrimination was not observed in the poor-risk group. Additionally, patients with high ADAM28 expression presented a significantly higher CIR than the low expression patients in the chemotherapy subgroup, whereas relapse did not differ significantly with the ADAM28 expression level in patients receiving transplantation. Interestingly, when the median or arithmetic average was taken as the cut-off value of ADAM28 expression, the result of the survival analyses had a similar trend in the favorable-risk group, which might indicate that ADAM28 was a valuable prognostic marker.
Summary/Conclusion: In summary, these data provide the first demonstration that high expression of ADAM28 correlates with a high risk of relapse in favorable risk AML patients. This correlation is seen in subjects receiving chemotherapy only but not in those also receiving an HSCT. However, whether these patients would benefit more from HSCT need further validation by prospective large-scale randomized clinical trials.

PB1690

FREQUENCY AND SIGNIFICANCE OF DICENTRIC CHROMOSOMES IN BONE MARROW CELLS OF PATIENTS WITH ACUTE MYELOID LEUKEMIA

S. Ransdorfova[1,*], I. Sarova[1], J. Brezinova[1], Z. Zemanova[2], L. Lizcova[2], L. Pavlistova[2], K. Svobodova[2], S. Izakova[2], K. Skipalova[2], L. Hodanova[2], A. Jonasova[3], C. Salek[4], K. Michalova[2]

[1]Cytogenetic Department, Institute of Hematology and Blood Transfusion, [2]Center of Oncocytogenetics, Institute of Medical Biochemistry and Laboratory Diagnostics, General University Hospital and First Faculty of Medicine, Charles University, [3]1st Medical Department, General University Hospital and First Faculty of Medicine, Charles University, [4]Clinical department, Institute of Hematology and Blood Transfusion, Prague, Czech Republic

Background: In 10-12% of patients with acute myeloid leukemia (AML) in bone marrow cells, complex karyotype (CK) is present in their initial cytogenetic evaluation. It is traditionally regarded as a poor prognostic factor, particularly in patients showing dicentric chromosomes.
Aims: The aim of the study was to review karyotypes of AML patients with CK and to verify the presence of dicentric chromosomes (DCs) by FISH with multi-centromeric probes. The frequency and prognostic significance of DCs in AML was evaluated as well.
Methods: During years 2006–2016, 607 adult patients with newly diagnosed AML (excluding the specific subtype of AML-M3) were examined by conventional cytogenetics. The complex aberrations were investigated using

multicolor fluorescence *in situ* hybridization (mFISH) and multicolor banding (mBAND). Monosomies were verified with the XCyting Centromere Multi-Color Probe Mix (MetaSystems), which is able to distinguish 18 chromosomal pairs in one test, and/or with a Vysis chromosome enumeration (CEP) probe (Abbott) and/or Satellite Enumeration (SE) FISH Probes SE 13/21 and SE 14/22 (Kreatech Diagnostics).
Results: CK was proved in 114 (19%) adult AML patients at diagnosis. Monosomy was detected in 63% of patients by conventional cytogenetics/mFISH, respectivly in 55% by centromeric FISH. Some of the losses were revised as the presence of a hidden DC. The use of centromeric FISH proved the increase of frequency of DCs in adult AML patients with CK from 27% (31/114) to 51% (58/114). In total, 79 dicentric, 2 tricentric, 1 quadricentric, and 12 isodicentric chromosomes were identified. DCs were often formed by chromosomes 17 and 20. Some DCs were observed repeatedly, however the breakpoints were not recurrent.
Summary/Conclusion: FISH analysis revealed high frequency of DCs in adult AML patients, particularly in bone marrow cells with complex karyotypes. Unbalanced aberrations leading to chromosomal losses indicate possible presence of hidden DC or its previous existence. DCs undergo variety of stabilization changes and can produce secondary monocentric derivative chromosome. DCs participate in raising of chromosomal instability (additional aberrations and new DCs) resulting in the clonal evolution of abnormal cells, which is associated with the adverse course of the disease and short survival of patients.

PB1691

A NGS-BASED APPROACH FOR MOLECULAR CLASSIFICATION OF ACUTE MYELOID LEUKEMIA (AML) WITH INTERMEDIATE PROGNOSTIC CYTOGENETIC RISK

L. Floreani[1], E. Toffoletti[1,*], A. Chiarvesio[2], S. Radovic[3], M. Morgante[3], D. Fabbro[4], G. Damante[4], A. Candoni[2], R. Fanin[1]

[1]Department of Experimental and Clinical Medical Sciences, Division of Hematology and BMT, University of Udine, [2]Hematological Division of Udine, Azienda Sanitaria Universitaria Integrata di Udine, [3]Istituto di Genomica Applicata, Istituto di Genomica Applicata, [4]Institution of Medical Genetics, Azienda Sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: Acute Myeloid Leukemia (AML) cases presenting intermediate-prognostic cytogenetic features account for about 40% of adult AMLs and display heterogeneous clinical outcomes. Over the past 2 decades an increasing number of molecular lesions, having prognostic and therapeutic significance, have been described in AML. Mounting evidence is showing that deep genomic characterization might provide an important tool to predict pathology progression. In line with these findings, two recent works (Grimwade *et al*., 2015 and Pappaemmanuil *et al*.,2016) proposed a genomic classification of AML that relies upon the study of a number of recurrent mutations.
Aims: Validation of a specific gene panel, having prognostic and therapeutic relevance, on AML patients (preliminary results).
Methods: Taking advantage of Next Generation Sequencing (NGS) Illumina MiSeq platform, we performed deep sequencing analysis of the following genes: ABL (exons 4-9), ASXL1 (exons 9,11,12,14), BRAF (exon 15), CALR (exon 9), CBL (exons 8,9), CEBPA (all gene), CSF3R (all gene), DNMT3A (all gene), ETV6 (all gene), EZH2 (all gene), FLTR3 (exons 13-15,20), HRAS (exons 2,3), IDH1 (exon 4), IDH2 (exon 4), JAK2 (all gene), KIT (exons 2,8-11,13,17,18), KRAS (exons 2,3), MPL (exon 10), NPM1 (exons 10,11), NRAS (exons 2,3), PTPN11 (exons 3,7-13), RUNX1 (all gene), SETBP1 (exon 4), SF3B1 (exons 10-16), SRSF2 (exon 1), TET2 (all gene), TP53 (exons 2-11), U2AF1 (exons 2,6), WT1 (exons 6-10), ZRSR2 (all gene). In this study, AML cases at onset, that presented intermediate-prognostic cytogenetic risk were considered. We analyzed a total of 11 samples, 5 of which had normal karyotype, 5 patients harboured intermediate cytogenetic alterations, 1 case had complex karyotype.
Results: From our analysis we were able to collect all analyzed AMLs into molecularly-defined subsets, according to what reported by Grimwade and Pappaemmanuil and colleagues. In particular, we observed 36% of cases harbouring NPM1 as driver-mutation, of which 100% displayed co-occurrence of FLT3 mutation. On the other hand, 36% of cases were RUNX1-mutated. In this latter group, 75% of cases associated with lesions in ASXL1 gene and 50% with additional chromosome 8. Finally, 18% of cases did not meet criteria with classes presenting NPM1 or RUNX1 driver mutations, whereas the sample with complex karyotype displayed simultaneous TP53 mutation (see table 1). Importantly, we noticed that all AML samples, apart from the one with complex karyotype, had molecular alterations on epigenetic modifiers, mainly IDH1-2, DNMT3A or, alternatively, TET2, that displayed Variant Allele Frequencies (VAF) equal to or higher than 0.5, suggesting that aberrant epigenetic pathways affect the majority of blast cells, therefore representing an early event in AML pathogenesis.

Table 1.

Table 1. Proposed genomic classification of AML cases with relative sample distribution and concomitant mutations per each subgroup (adapted from Papaemmanuil et al.,2016)

Genomic subgroup of AML *as indicated by Papaemmanuil et al.,2016*	Frequency in the study cohort (N=11) *no. of patients (%)*	Most frequently molecular alterations *driver mutation (%), concomitant mutated genes or cytogenetic alterations (%)*
AML with NPM1 mutation	4 (36)	**NPM1 (100)**, FLT3 (100), CEBPA (50), ASXL1 (25), DNMT3A (25), IDH1 (25), TET2 (25), NRAS (25), del20q11 (25)
AML with mutated chromatin, RNA-splicing genes, or both	4 (36)	**RUNX1 (100)**, ASXL1 (75), +8 (50), DNMT3A (50), SETBP1 (50), IDH1 (50), SRSF2 (50), IDH2 (25),TET2 (25), +11 (25), t(1;9) (25)
AML with TP53 mutations, chromosomal aneuploidy, or both	1 (9)	**TP53 (100)**, complex karyotype (100), CBL (100), CEBPA (100)
AML with no detected driver mutations	2 (18)	TET2 (100), BRAF (50), FLT3 (50), WT1 (50), -Y (50), +8 (50)

Summary/Conclusion: Although the combinatorial effect of different molecular lesions remains to be uncovered, our data show that the emerging genomic classification system might represent a reproducible method for AML characterization based on molecular approaches.

PB1692

IDENTIFICATION OF A LONG NON-CODING RNA (LNCRNA) ASSOCIATED WITH FAVORABLE OUTCOME IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

A. Neddermeyer[1,*], Y. Qu[2], K. Karlsson[3], M. Björklund[1], S. Mareschal[1,4], C. Nilsson[2], S. Bengtzén[2], A. Lennartsson[4], S. Lehmann[1,2]

[1]Medical Sciences, Uppsala University, Uppsala, [2]Medicine, [3]Medical Biochemistry and Biophysics, [4]Biosciences and Nutrition, Karolinska Institutet, Stockholm, Sweden

Background: Acute myeloid leukemia (AML) is the most frequently diagnosed type of acute leukemia in adults, with a dismal 5-year relative survival of only 25.9%. Efforts to improve prognosis focus on elucidating the mechanism behind AML development, to improve risk classification using novel biomarker and establishing new means for personalized treatment. Non-coding parts of the transcriptome, such as long non-coding RNAs (lncRNAs) exhibit crucial regulating functions and their dysfunction is often associated with cancer. However, the functional role of lncRNAs in the development and progression of AML is so far poorly understood.
Aims: In this study, we aimed to identify long non-coding RNAs (lncRNAs), which are differentially expressed in AML and study their role on leukemogenesis. We hypothesized that these non-coding transcripts could potentially play important biological roles in the development or progression of AML, serve as novel prognostic or predictive biomarkers or could indicate new treatment targets in AML.

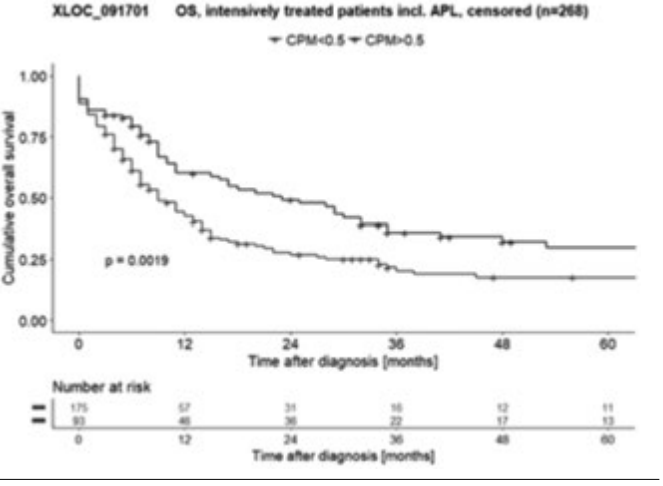

Figure 1.

Methods: We performed deep RNA-sequencing in a subset of AML samples and normal CD34+ bone marrow cells and identified, among others, lncRNA XLOC_091701 (internal reference), which is upregulated in AML. TSS peaks of XLOC_091701 were confirmed using FANTOM CAGE data

(RIKEN) and XLOC_091701 expression was validated in ten myeloid cell lines using RT-qPCR. Further, XLOC_091701 expression was validated using RNA expression data from our AML patient cohort (n=325, ClinSeq cohort) and confirmed by The Cancer Genome Atlas (TCGA)-LAML cohort (n=151). Next, multivariate cox regression analysis and clinical correlation analysis was done to identify significant correlations with clinical parameters and survival using available clinical data on intensively treated AML patients (n=268, ClinSeq-AML cohort).
Results: We found XLOC_091701 to be exclusively expressed in certain myeloid cell lines, especially in HL60 and U937 cells, and expressed in about a third of all tested AML patients in both ClinSeq-AML cohort (n=268) and TCGA-LAML cohort (n=117, cut-off: CPM>0.5). Next, multivariate cox regression revealed significant superior survival in patients with XLOC_091701 expression independent of other variates known for good prognosis (n=268, ClinSeq-AML cohort, p=0.002) and moreover associates with formerly used AML FAB classification M2 and M3 (APL) along with low genetic and low cytogenetic risk groups.
Summary/Conclusion: Here, we describe a long non-coding RNA transcript (XLOC_091701) whose expression is associated with better overall survival in AML patients. Our findings suggest that XLOC_091701 plays a biological role in AML and might serve as prognostic biomarker in clinical settings. Currently, we are creating a KO-model to characterize XLOC_091701 functionally to explore the regulatory mechanisms behind the observed favorable prognosis.

ROLE OF CLEC12A IN THE LSC COMPARTMENT OF PEDIATRIC ACUTE MYELOID LEUKEMIA AT DIAGNOSIS *VERSUS* RELAPSE

B. Depreter[1,2,*], D. Hanekamp[3], T. Lammens[4], B. De Moerloose[4], E. Sonneveld[5], B. Denys[2], A. De Jong[5], G.J. Kaspers[6,7], G.J. Schuurhuis[7], J. Philippé[2], J. Cloos[3]

[1]Department of Paediatric Haematology-Oncology and Stem Cell Transplantation, [2]Department of Laboratory Medicine, Haematology, Ghent University Hospital, Ghent, Belgium, [3]Department of Haematology, VU University Medical Center, Amsterdam, Netherlands, [4]Paediatric Haematology-Oncology and Stem Cell Transplantation, Ghent university hospital, Ghent, Belgium, [5]Dutch Childhood Oncology Group, The Hague, [6]Princess Maxima Center for Paediatric Oncology, Utrecht, [7]Department of Paediatric Oncology/Haematology, VU University Medical Center, Amsterdam, Netherlands

Background: Despite high clinical remission rates (90%), pediatric acute myeloid leukemia (pAML) patients exhibit a high risk of relapse (30-40%). Recently, the leukemic stem cell (LSC) load at diagnosis, determined as $CD34^+/CD38^-/CD45^{low}$ cells expressing an aberrant marker, was shown to be an independent prognostic factor for relapse in pAML. Nevertheless, the flow cytometric aberrancies of LSCs remain poorly described. In adult AML, it was shown that the stem cell-associated antigen CLEC12A (CD371, CLL-1) strongly aids in discriminating normal hematopoietic stem cells (HSCs) from LSCs.
Aims: To evaluate the frequency and specificity of CLEC12A in the LSC fraction of pAML at diagnosis and relapse.
Methods: Bone marrow (BM, n=6) and/or peripheral blood (PB, n=4) of seven pAML patients were taken at diagnosis and relapse. For three patients, BM and PB was available at both time points. FCM data acquisition for CLEC12A (PE, clone 50C1) was performed together with backbone markers CD34 (PerCP-Cy5.5), CD38 (APC-H7) and CD45 (PacO or V500). All samples were analyzed on a 3-laser, 8-color FACSCanto II (BD) with instrument set-up performed according to EuroFlow guidelines. Within the $CD34^+/CD38^-$ (10^3 cut-off for CD38) stem cell compartment, expression of CLEC12A was analysed using the lymphocytes as negative control. In addition, $CD34^+/CD38^-$ cells from cord blood (CB, n=8) and normal pediatric bone marrow (NBM, n=6) were used to evaluate CLEC12A expression on normal HSC. Data analysis was performed using Infinicyt software v.1.8 (Cytognos, Salamanca, Spain) with a previously described gating strategy. Paired samples t-test was used to calculate statistical significance.
Results: The median blast percentage (% of white blood cells (WBC)), and CD34+ fraction within the blasts, was 40% and 64%, respectively, at diagnosis and 64% and 62%, respectively, at relapse. Total events measured ranged between 8575-1027340 (median 221579). Differences between the median $CD34^+CD38^-$ load within the WBC compartment at diagnosis *versus* relapse were not significant in our cohort (BM: 0.08% *versus* 0.13%, PB: 0.07% *versus* 0.27%; P>0.05). At diagnosis, five out of seven patients showed aberrant CLEC12A expression, with a median CLEC12A pos/CLEC12A neg ratio within the $CD34^+CD38^-$ compartment of 1.55 (range 0.46-20, BM=4, PB=3). The percentage of CLEC12A positive $CD34^+CD38^-$ cells of ranged between 4-95% (median 44%). At relapse, only one patient lost CLEC12A expression. CLEC12A pos/CLEC12A neg ratios were not significantly different at relapse (range 0-26, median 0.18) compared to diagnosis (range 0-20, median 0.49) in regard to the other six patients (BM=5, PB=3) (P>0.05). Analysis of PB was highly comparable to BM for the three patients with paired BM and PB samples. Importantly, no CLEC12A positive stem cell population (≥4 events and clustered on SSC/FSC) was observed within the $CD34^+/CD38^-$ compartment of pediatric NBM or CB.
Summary/Conclusion: This report describes the frequency of aberrant CLEC12A expression in LSC in pAML. These data suggest that CLEC12A is a valuable and specific marker in children to discriminate leukemic from normal HSC.

PB1694

SYNERGISTIC EFFECTS OF PI3K AND C-MYC CO-TARGETING IN ACUTE MYELOID LEUKEMIA: PROPOSING NOVEL THERAPEUTIC POTENTIAL FOR AML

N. Riyahi*, N. Sheikh-Zeineddini, M. Sayyadi, D. Bashash

Department of Hematology and Blood Banking, School of Allied Medical Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: Interest into targeting PI3K pathway has elevated by the latest accomplishments which manifest that overexpression of PI3K not only is contributed to disease progression but also is associated with poor outcome in patients with leukemia. Despite the broad spectrum efficacies, drug resistance on account of multiple interfering factors, such as overexpression of c-Myc is known to be still a daunting challenge for the successful application of PI3K inhibitors.
Aims: To delve into whether c-Myc suppression could intensify the antitumoral effects of PI3K inhibitor in AML cells, U937 and KG1 cells were subjected to treatment with CAL-101 and 10058-F4.
Methods: Cell viability, growth kinetics, DNA synthesis rate, induction of apoptosis, and caspase-3 activity were assessed after exposing the cells with both individual and combination treatments of the drugs. Moreover, gene expression analyses by using quantitative real-time PCR were applied to examine the effects and molecular mechanisms of CAL-101 and 10058-F4 combination.
Results: Our results demonstrated that single agent of CAL-101, as the excelled member of PI3Kδ inhibitor, induced cytotoxic and growth suppressive effects through shifting the ratio of death promoters to death repressors via amendment of pro- and anti-apoptotic genes expression. Moreover, PI3K inhibition resulted in a concentration-dependent induction of apoptosis coupled with the enzymatic augmentation of caspase-3, as a substantial executioner of the apoptotic pathway. Noteworthy, the apoptotic effect was even more evident in combinational treatment, as the percentage of apoptotic dead cells was robustly higher in the cultures of AML cells co-treated with CAL-101 and 10058-F4. To investigate whether the augmentative impact of c-Myc inhibitor is a general feature in PI3K inhibition, we evaluated the effect of 10058-F4 in combination with pan-PI3K inhibitor BKM120. Of particular interest and in agreement with the results of CAL-101, it became evident that abrogation of c-Myc using 10058-F4 could enhance the tumor suppressive assets of the PI3K inhibition in acute myeloid leukemia.
Summary/Conclusion: Taken together, our findings not only highlighted that PI3K inhibition is a promising approach in AML but also illustrated the favorable therapeutic prospective for PI3K inhibitors in combination with 10058-F4.

PB1695

CHONDROITIN SULPHATE PROTEOGLYCAN 4 POTENTIAL MARKER OF MINIMAL RESIDUAL DISEASE IN ACUTE MYELOID LEUKEMIA AND BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM

M. Hisemová[1,*], V. Válková[1], I. Marinov[1], M. Marková[1], J. Polák[2]

[1]medical department, [2]department of genomics, Institute of Hematology and Blood Transfusion, Prague [2], Czech Republic

Background: A key prognostic factor in acute leukemia is the monitoring of minimal residual disease (MRD). Methods are based on flow cytometry, as well as molecular biology methods using reverse transcriptase quantitative polymerase chain reaction (RT-qPCR). The RT-qPCR methodology enables us to follow MRD-specific markers or non-specific markers such as WT1.
Aims: Assessment of suitable molecular-biological markers of MRD in patients with AML, and in patients with rare hematologic malignancy Blastic Plasmacytoid Dendritic Cell Neoplasm (BPDCN).

Methods: Expression of the non-specific marker *WT1* was tested according to the European Leukemia Net protocol (ELN) using a WT1 ProfileQuant kit (Qiagen). To monitor the expression of *Chondroitin Sulphate Proteoglycan 4 (CSPG4),* one of the Leukemia Associated Antigens (LAA), we used a TaqMan Gene Expression Assay (ThermoFisher). The data were normalized to the expression of the *ABL* control gene TaqMan Gene Expression Assay with results in relative units (ru); upper normal limit is ru=1.00. Similarly, we measured the expression of the *XAGE1 gene,* another LAA. Additionally, an in-house methodology was established to obtain *CSPG4* absolute quantification, showing *CSPG4* copy number normalized to 10^4 copies of the *ABL* reference gene. Leukemia-Associated Immunophenotype (LAIP) measured by flow cytometer also monitored the MRD.
Results: In 170 patients with AML, *CSPG4* expression with a median expression of 0.517 was measured at diagnosis. Significantly increased expression of this marker was found in the AML M5 subtype (n=17, median=20.51, P 0.0001), in AML possessing a MLL translocation (n=12, median=59.15, P 0.0001), and in 4 patients with BPDCN (median=74.26, P=0.0001); all related to *CSPG4* values measured in peripheral blood of healthy donors (n=22, median=0.262). The median expression of the *CSPG4* in BPDCN patients was nearly 2 orders above the normal upper limit. No specific MRD marker is available in patients with BPDCN, and *WT1* expression at diagnosis is uniformly low. We validated the measurement of *CSPG4* expression in 4 patients by comparison with *WT1* and *XAGE1* expressions, reaching a high correlation (P=0.05, P=0.0006, P=0.0002, and P<0.0001). The MRD level was monitored in all patients at diagnosis, after induction therapy, after consolidation therapy, and after allogeneic stem cell transplantation (ASCT). The expression of this MRD marker correlated with the clinical status of the patients, as well as with flow cytometric data. Subsequently, a *CSPG4* absolute quantification methodology was developed and validated.
Summary/Conclusion: MRD monitoring in patients with AML has prognostic significance. By monitoring the expression of *CSPG4*, we found that it was overexpressed in patients with AML with *MLL* translocation, with AML M5 subtype, and in a rare BPDCN entity. Common features of the AML patients with *MLL* translocation and the BPDCN patients are poor prognosis and low *WT1* expression at diagnosis. We validated the methodology for monitoring of this alternative marker at the mRNA level instead of *WT1.* The *CSPG4* expression was in agreement with the clinical and flow cytometric data of the patients. Further prospective monitoring of this marker is necessary.Conclusion:*CSPG4* appears to be a potentially suitable molecular marker of MRD in AML M5, AML with *MLL* translocation and BPDCN. Supported by MH CZ-DRO UHKT 00023736

Hospital Universitari Germans Trias i Pujol. Institut d'investigació contra la leucèmia Josep Carreras. Universitat Autònoma de Barcelona., Badalona, Spain

Background: Acute Myeloid Leukaemia with isolated 13 trisomy (AML +13), is classified as intermediate risk-II according with the European Leukaemia Net group (ELN), and has a worse relapse-free and overall survival compared to the other ELN intermediate-II patients, with a median overall survival of 9,3 months. AML +13 has an incidence of 0,7%, it's associated with undifferentiated morphology and immunophenotype features, and the hand-mirror blast cells are a characteristic finding. Previous works has suggested that AML +13, has a characteristic mutational profile with mutations of RUNX1, *SRSF2*, *ASXL1*, BCOR and CEBPZ.
Aims: To describe retrospectively the clinical, biological and morphological data from a cohort of 9 patients diagnosed of AML +13 and compare it with the AML +13 patients from Mehta *et al.*[1] and Harold *et al.*[2] cohorts.
Methods: We collected clinical, morphological and genetic data from 9 patients diagnosed of AML +13 in 5 Catalan hospitals, from September 2013 to May 2017.For the mutational analysis, we used next generation DNA sequencing with a panel of 32 genes often mutates in myeloid malignancies *(ABL1,ASXL1,BRAF,CARL,CBL,CEBPA,CSF3R,CSNK1A1,DNMT3A,ETV6,EZH2,FLT3,HRAS,IDH1 IDH2,JAK2,KIT,KRAS,KMT2A, MPL,NPM1,NRAS,PTPN11,RUNX1,SETBP1,SF3B1,SRSF2,TET2,TP53, U2AF1,WT1,ZRSR2*). We used MiSeq Illumina System and SOPHIA DDM software for data analysis.
Results: The most frequently mutated genes in our cohort were *RUNX1*(7/8, 88%), *ASXL1* and *SRSF2*(4/8, 50%), *DNMT3A*, *FLT3* and *TET2*(3/8, 38%). Other less frequent mutated genes were *IDH2, KMT2A, ZRSR2*(2/8, 25%) and *EZH2, IDH1, U2AF1, SETBP1, WT1* and *CBL*(1/8,13%). In Harold *et al.* cohort, the genes most frequently mutated were *SRSF2* 81%, *RUNX1* 75%, *ASXL1* 44%, *BCOR* 25%, *TET2* 19%, *IDH2* 19% among others, which is comparable with our cohort.In our cohort(n=9) the median age was 72 years-old [58-89], there was a male predominance(8:1), hand-mirror blast cells and small blast cells were present in 89% and 78% of cases, respectively and according FAB classification patients were diagnosed of M0 (n=4), M1(n=4) and M2(n=1), without dysplasia in any case. In the Metha's cohort(n=23), the median age was 66 years-old, a male predominance(17:6), hand-mirror blast cells and small blast cells were present in 52% and 71% of cases and FAB classification was M0(n=11), M1(n=6), M2(n=2), M4(n=2), M5(n=1), M6(n=1); very similar and comparable with our results. Three patients were treated with intensive cytarabine-based chemotherapy and one of them underwent allo-transplant, being alive after 6 years from the diagnosis. One patient was treated with hypomethylanting agents, one patient was included in a clinical trial and four patients aged >70 years old received only best supportive treatment. Four patients died due to sepsis (one of them during reinducction after relapse) and four patients died due to haemorrhage. The median overall survival was 8,1 months[0,16-33], being the results comparable with those of other series.

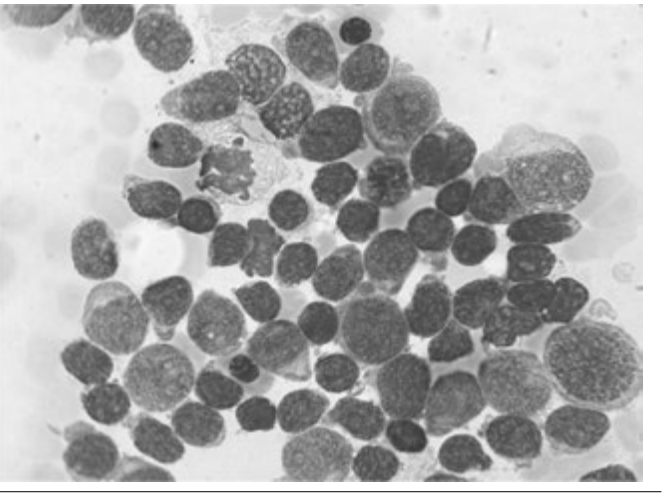

Figure 1.

Summary/Conclusion: The results of our series were comparable to those described in other series, which supports the different biological and therapeutic behavior from this AML group compared with other AML of the same risk group, according to the ELN.It's possible that the mutational profile, with frequent mutations in the *RUNX1, ASXL1, SRSF2*, and other genes related to resistance to treatment and less survival, plays a crucial role with the different behavior that AML +13 presents, requiring further studies with larger series to be able to confirm it, and to assess its inclusion as a differentiated entity within the WHO classification.

PROGNOSTIC IMPACT OF DNMT3A MUTATIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML) WITH NPM1MUTATION DEPENDING ON FLT3 MUTATIONAL STATUS

G. Oñate[1,*], A. Garrido[1], A. Aljarilla[1], J. Esteve[2], M. Arnan[3], R. Guardia[4], M. Tormo[5], S. Vives[6], O. Salamero[7], L. Escoda[8], A. Sampol[9], J. Bargay[10], M.P. Queipo de Llano[11], A. Garcia[12], S. Brunet[1], J. Sierra[1], J. Nomdedeu[1], M. Pratcorona[1]

[1]Hematology, Hospital Santa Creu i Sant Pau, [2]Hematology, Hospital Clinic,

Barcelona, [3]Hematology, Institut Catala d'Oncologia Bellvitge, Hospitalet de Llobregat, [4]Hematology, Hospital Josep Trueta, Girona, [5]Hematology, Hospital Clínico, Valencia, [6]Hematology, Hospital Germans Trias i Pujol, Badalona, [7]Hematology, Hospital Vall d'Hebron, Barcelona, [8]Hematology, Hospital Joan XXIII, Tarragona, [9]Hematology, Hospital Son Espases, [10]Hematology, Hospital Son Llatzer, Palma de Mallorca, [11]Hematology, Hospital Virgen de la Victoria, Málaga, [12]Hematology, Hospital Arnau de Vilanova, Lleida, Spain

Background: The association of *NPM1*mut and the internal tandem duplication of *FLT3* (*FLT3*-ITD) in *de novo* AML with intermediate-risk cytogenetics has different prognostic impact according to the *FLT3*-ITD/*FLT3*wt ratio, thus affecting clinical decisions about the indication of allogeneic hematopoietic stem cell transplantation (alloHSCT) in first complete remission (CR1). DNMT3A mutations (*DNMT3A*mut*)* have been suggested to have an adverse prognostic impact in this group of patients; however the effect of this triple mutation association is not well established.
Aims: To evaluate the prognostic value of additional *DNMT3A*mut in *de novo* AML with *NPM1*mut and *FLT3*-ITD, and its survival impact according to *FLT3* ratio.
Methods: Patients with *de novo* AML, intermediate-risk cytogenetics and *NPM1*mut were selected from CETLAM database, from our cooperative group protocols AML-2003 and AML-2012. Bone marrow samples from diagnosis were studied for *DNMT3A* mutations as previously described. The Kaplan-Meier test was used to estimate overall survival (OS) and leukemia-free survival (LFS), whereas risk of relapse (RR) was analysed by the cumulative incidence estimator with non-relapse mortality as the competing event.
Results: A total of 114 patients were selected from protocol AML-2003 (n=49) or AML-2012 (n=65). Median age was 51 years (18-71), with 54% females, median leucocyte count 42x10E9/L (1.2-408x10E9/L) and median bone marrow blasts 78% (20-100%). *FLT3* status was defined as wild type (n=34) or *FLT3*-ITD (n=76). High ratio (*FLT3*high) was considered when ≥0.50(n=43) and low ratio (*FLT3*low) when<0.5(n=33). *DNMT3A*mut was detected in 60 patients, the majority in amino acid R882(n=48). In patients with *NPM1*mut and *FLT3*-ITD, *DNMT3A*mut *vs DNMT3A*wt had no impact in 5 year OS (n=80): 40%±10% *vs* 56%±6% (p=0.28) or 5 year LFS (n=70): 27%±12.6% *vs* 55%±1% (p=0.105). Similarly, when divided according to *FLT3* status (*FLT3*wt *vs FLT3*low *vs FLT3*high) *DNMT3A*mut had no significant prognostic impact in 5 year OS (n=58) 70%±11% *vs* 58%±13% *vs* 28%±13% (p=0.104); 5 year LFS (n=54) 67%±12% *vs* 44%±13% *vs* 19%±14% (p=0.073); or RR (n=54) 20.4% (95%CI 2.6%>49.8%) *vs* 35.6% (95%CI, 11.4%>61.1%) *vs* 52.2% (95%CI, 24.7%>73.9%) p=0.117. Thirty-six patients of the entire cohort received alloHSCT in CR1. When censoring follow-up at the date of transplant, RR analysis confirmed an increasing risk in *DNMT3A*mut patients according to *FLT3* status: *FLT3*wt 23.4% (95% CI, 2.8%>55.4%; n=30) *vs FLT3*low 49.8% (95% CI, 13.8%>78.2%; n=28) and *FLT3*high 56.6% (95% CI, 23.2%>80.2%; n=32) p=0.0113. *DNMT3A*mut effect was analysed in *FLT3* subgroups, showing impact only in *FLT3*wt *vs FLT3*high 23.4% *vs* 56.6% (p=0.014), and a trend in *FLT3*low *vs FLT3*high 49.8% *vs* 56.6% (p=0.077). No significant differences were seen in *FLT3*wt *vs FLT3*low 23.4% *vs* 49.8% (p=0.178).
Summary/Conclusion: It has been established that AML with *NPM1*mut and *FLT3*low has better outcome than *FLT3*high. Overall, our study suggests that *DNMT3A* mutations do not have survival impact in AML with *NPM1*mut and *FLT3*-ITD. However, when RR is censored by date of alloHSCT in CR1, *DNMT3A*mut shows a trend to a higher relapse risk when associated to *FLT3*-ITD; this could be of clinical relevance in patients with a low *FLT3*-ITD ratio who are currently not considered for alloHCT in CR1 in our group. These results should be confirmed in future studies that gather a higher number of patients and may include the evaluation of measurable residual disease (MRD) that could anticipate patients with an inadequate MRD clearance who could benefit from alloHCT in an early phase.

HAEMATOLOGICAL CANCERS & THE 100,000 GENOMES PROJECT-CREATING CLINICAL PATHWAYS TO ENABLE WHOLE GENOME SEQUENCING IN A DIAGNOSTIC SETTING

S. Henderson[1,*], A. Hamblin[2], A. Sosinsky[2], C. Turnbull[2], L. Jones[2,]
S. Hing[1], N. Murugaesu[2], J. Moorhead[1], T. Fowler[2], Z. Deans[1,]
A. Schuh[3], M. Caulfield[2], S. Hill[1]

[1]NHS England, [2]Genomics England, London, [3]Oncology, Oxford University, Oxford, United Kingdom

Background: The 100,000 Genomes Project in England is an initiative to sequence 100,000 genomes from patients with rare disease and cancer. One of the goals of the Cancer Programme is transformation with the aim of creating and embedding clinical pathways into National Health Service (NHS) care allowing cancer patients in the future, equitable and rapid access to Whole Genome Sequencing (WGS) which has the potential to simultaneously detect all types of variant and new predicative biomarkers such as mutational signatures. During 2017 eligibility for the Project was widened to include patients with haematological malignancies. Although there is a long track record of genetic analysis of both liquid and solid haematological tumours to aid diagnosis and therapy choice, significant clinical pathway adaptions are required to provide appropriate material for WGS.
Aims: For solid haematological tumours adaptions have mainly focused around the need to provide tumour DNA of sufficient quantity and quality for WGS which has driven the collection of fresh frozen samples from tumour types which would normally be processed in formalin (e.g. lymphoma). For liquid haematological cancers where it is usually possible to obtain good quality (unfixed) tumour DNA from blood or bone marrow, the challenge lies with the collection of suitable samples for germline (GL) DNA. It is usual practice in cancer WGS to sequence tumour and GL DNA samples to allow GL variants to be subtracted from the tumour sequence aiding the interpretation of somatic variants. For most cancer types a blood sample can be used as the source of GL DNA. However, collecting an equivalent GL sample from patients with many subtypes of haematological malignancy is difficult: if malignant cells are present in the blood or bone marrow, leucocyte DNA is unsuitable as it may contain tumour-specific acquired genetic changes.
Methods: Alternative GL DNA sources used in research include salvia, cultured fibroblasts from skin biopsies or post treatment blood taken once malignant cells have been cleared. The main disadvantages of these are potential tumour contamination and/or the delay between obtaining the tumour sample and the GL sample which would be problematic if WGS is to be used in diagnostic pathways.
Results: Work has been carried out to optimise the source of GL DNA for each type of haematological malignancy and appropriate solutions have been adopted. These include DNA extracted from saliva which has been collected post chemotherapy (once myeloid cells have been cleared from the blood) and cultured fibroblasts, often considered the 'gold standard' GL source. Measures to mitigate the effect of delayed GL collection include a two-step WGS analysis approach where the sequence is initially analysed using a reference GL sequence to identify urgent prognostic and diagnostic markers with subsequent more comprehensive analysis performed when the patient GL DNA is available. Additional studies have explored the practicality of using DNA extracted from sorted T cells for GL DNA which can be obtained at the time of diagnosis without incurring delays. This includes ensuring that sufficient T cell DNA of suitable purity can be robustly obtained and if the potential presence of genomic variants associated with clonal haematopoiesis of indeterminate potential (CHIP) would be compatible with current WGS analysis pipelines.
Summary/Conclusion: Due to this work we are now seeing the development of viable clinical pathways which will ensure that NHS patients with haematological malignancies can benefit from the diagnostic and therapeutic potential of WGS.

PB1699

HIGH-THROUGHPUT DRUG SCREENING TO IDENTIFY THERAPIES REVERSING ABERRANT CELL DIFFERENTIATION IN AML

E. Karjalainen[1,*], M. Wolf[1], G. Repasky[1], K. Wennerberg[1,2]

[1]Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland, [2]Biotech Research & Innovation Centre, University of Copenhagen, Copenhagen, Denmark

Background: Acute myeloid leukemia (AML) is a malignancy characterized by impaired cell differentiation and uncontrollable accumulation of immature myeloid progenitor cells in the bone marrow. Although most patients respond to the first line chemotherapeutic treatment, the majority of patients eventually relapse and therefore the overall survival from AML remains very poor. A therapy based on inducing the immature leukemic cells to differentiate may turn AML into a curable disease, as has been shown in the case of Acute Promyelocytic Leukemia (APL), the M3 subtype of AML. However, AML is a heterogeneous disease and we still lack knowledge of how different genetic alterations disturb normal hematopoiesis and how the cell differentiation blockade may be lifted in the various subtypes of AML.
Aims: Our aims are 1) to identify therapies reversing aberrant cell differentiation in AML by using flow cytometry-based high-throughput drug screening 2) to establish links between molecular subtypes of AML and responsiveness to identified cell differentiating therapies.
Methods: Our approach is to explore drug-induced cell differentiation in primary samples from AML patients and genetically engineered AML mouse

models using high-throughput flow cytometry. Specifically, we characterize samples by their expressed cell differentiation-related cell surface markers with and without drug treatment to identify compounds capable of inducing cell differentiation *ex vivo*. The primary AML patient samples are also profiled by exome- and RNA-sequencing.
Results: Preliminary results with a *Flt3/Npm1* –mutated mouse model suggest that several compounds elicit cell differentiation-state specific responses, some of which could be indicative of a dynamic shift towards cell differentiation. For example, treatment with mTOR-kinase inhibitors sapanisertib and vistusertib resulted in a concentration dependent increase of differentiating cells marked by CD11b expression and decrease of stem cells marked by CD34 expression.
Summary/Conclusion: We have established a high-throughput flow cytometric screening platform to identify drugs that are able to induce differentiation in primary AML samples and genetically engineered mouse models of AML. By integrating drug response data with genetic background information from samples we aim to reveal novel genotype-phenotype relationships in the level of cell differentiation that could eventually be translated into clinically relevant biomarkers and treatment options for AML patients.

DETECTION OF FLT3-INTERNAL TANDEM DUPLICATION WITH NGS: A COMPARISON OF DIFFERENT ANALYTICAL TOOLS

M. Le Mercier[1,*], K. Vermeulen[1], C. Weyn[2], S. Van Lent[1], D. Lathauwers[1], C. De Beul[1], P. Holmgren[3], J. Van Den Bossche[1], R. Malfait[1], K. Deiteren[1], M.-B. Maes[1]

[1]Laboratory of Hematology, [2]Laboratory of Pathology, [3]ICT department, Antwerp University Hospital, Edegem, Belgium

Background: Internal tandem duplication (ITD) in the FLT3 tyrosine kinase gene is a somatic genetic alteration frequently found in acute myeloid leukemia (AML) and is associated with an aggressive phenotype. The accurate detection of FLT3-ITD together with evaluation of the mutant-to-wild-type allelic ratio are essential due to the strong prognostic and the potential therapeutic relevance of this marker in AML. The gold standard method for the detection of FLT3-ITD consists of PCR and electrophoresis-based product sizing. In the last years, as the number of relevant genetic alterations in myeloid neoplasm is increasing, next generation sequencing (NGS) has started to replace the conventional PCR methods in clinical diagnostic labs. However, NGS methods are usually not very performant for the detection of medium sized or long insertions or deletions.
Aims: The aim of this study was to evaluate the possibility to use NGS for accurate detection of FLT3-ITD in the daily practice.
Methods: We have developed a custom Haloplex NGS panel (Agilent) to sequence 29 genes related to myeloid neoplasm, among which FLT3 exons 14, 15 and 20. We used this panel on a MiSeq (Illumina) sequencing platform on 40 AML samples (23 FLT-ITD negative samples and 17 FLT-ITD positive samples) and compared the performance for FLT3-ITD detection of several analysis tools, both technical (different sequencing cartridges and analytical (Pindel, SOPHiA DDM and SeqNext).
Results: Best results for FLT3-ITD detection were obtained using 500v2 cartridge instead of 300v2. Regarding analysis software Pindel and *SOPHiA* DDM gave the best results in terms of detection (more than 88%). However, large differences were observed between NGS and fragment analysis regarding the mutant-to-wild-type ratio.
Summary/Conclusion: These results demonstrate that FLT3-ITD can be detected reliably with NGS. However, optimization is still needed to accurately determine the mutant-to-wild-type ratio since this ratio is an important aspect of the prognostic value of FLT3-ITD.

Background: Whole-genome sequencing has revealed a central role of epigenetic modulators in acute myeloid leukemia (AML) pathogenesis. Targeted therapy has also focused on epigenetics as seen by the use of IDH and BET-inhibitors. We believe that establishing the expression profile of epigenetic modulators in AML may help in the understanding of AML genesis, biology, evolution and treatment.
Aims: We wanted to get a better insight regarding the expression profile of epigenetic modulators in AML of intermediate risk by studying expression levels of EZH2, ASXL1, TET2, BRD4, c-myc and Bcl-2 in a consecutive series of AML patients at diagnosis and after induction and its association with clinical evolution.
Methods: Our series consisted of 120 intermediate-risk AML patients with a mean age of 56.04 years (range 15-79 years), diagnosed and homogenously treated between 2005 and 2017 at the Hospital Universitario de Gran Canaria Dr. Negrín with a median follow up of 14 months. Gene expression analyses were carried out by real time PCR in a LightCycler 480 Instrument II (Roche) using ABL as a control gene. Results were normalized with a cDNA pool from the bone marrow of 10 healthy donors, which was introduced as an internal control in each experiment. For statistical analyses, SPSS (v.15.0) software was used.
Results: ASXL1 levels were positively associated with EZH2 (Spearman's coefficient, SC=0.4, p<0.001). BRD4 expression was strongly correlated with ASXL1 (SC=0.56, p<0.001) and EZH2 (SC=0.31, p<0.001) and with c-myc expression (SC= 0.25, p=0.01). On the other hand, TET2 expression showed a positive relationship with BRD4 (SC=0.23, p=0.01), EZH2 (SC=0.24, p=0.01) and ASXL1 (SC=0.2, p=0.01). As shown in Fig.1 TET2 levels at diagnosis were marginally significantly lower in those cases that persisted or died compared to those that reached complete remission after induction (mean 0.19 *vs* 0.24, p=0.06). Measurement of BRD4 levels after induction showed that patients that displayed a reduction of more than 95% compared to levels at diagnosis exhibited worse overall survival (median overall survival, OS, 14 months *vs* 28 months, p=0.046).

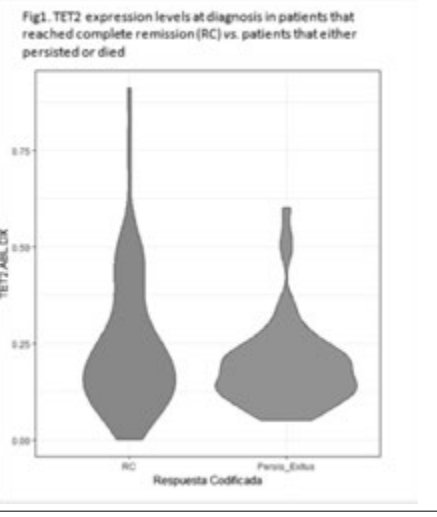

Figure 1.

Summary/Conclusion: The positive association observed between EZH2 and ASXL1 agrees with the fact that both cooperate in adding the epigenetic repressive H3K27 mark. In general, it seems that expression levels of genes that behave as tumor suppressor genes in AML, such us TET2, ASXL2 and EZH2, correlate well with BRD4 expression. BRD4 and c-myc levels were associated in accordance with what has previously been described, since BRD4 binds c-myc superenhancer regions, activating its expression. In contrast, lower levels of TET2 at diagnosis and a reduction of BRD4 levels after induction compared to diagnosis seemed to be related to worse prognosis. Further studies with a larger series are needed to confirm these preliminary results.

PB1702

BONE MARROW PLASMA LEVELS OF S100A8 ARE SIGNIFICANTLY INCREASED IN SOME SUBGROUPS OF AML PATIENTS WITH BETTER PROGNOSTIC

J. Mondet[1,2,*], M. Meunier[1,3], C. Lo Presti[1,4], E. Giraudon[5], M.-C. Jacob[6], C. Lefebvre[7], S. Berthier[8], A. Mc Leer-Florin[2], S. Park[1,3], P. Mossuz[4]

[1]UGA/INSERM U1209/CNRS 5309, Institute for Advanced Biosciences, [2]Pathologie moléculaire, [3]Department of clinical hematology, [4]Department of biological hematology, [5]CHU Grenoble Alpes, Grenoble, France, [6]Immunology

laboratory, [7]Oncohematology laboratory, [8]Flow cytometry platform, CHU Grenoble Alpes, Grenoble, France

Background: Increased intrablastic S100A8 has been associated with poor prognosis in AML. Moreover, its extracellular damage-associated molecular pattern activity regulates progression through genotoxic stress and myeloid differentiation independently of its frequently co-expressed protein S100A9. But extracellular S100A8 expression is not completely understood in AML.
Aims: In this context, we hypothesized that S100A8 can be secreted into BM niche and probably influences leukemic cell behavior and characterized its presence in AML.
Methods: Thus, we measured the level of S100A8 ([S100A8]) in 71 bone marrow plasma including 50 *de novo* AML, 12 myeloproliferative neoplasms (MPN), 7 myelodysplastic syndromes (MDS) and 9 healthy donors by ELISA technique. All patients gave their informed consent.
Results: Firstly, we found AML patients had significantly higher rates than healthy subjects but also than MDS or MPN patients. A significant correlation between bone marrow and blood plasma existed but bone marrow [S100A8] was 7 times higher than blood levels. We found a direct link between [S100A8] and the intensity of cell proliferation (peripheral and medullar leukocytosis). The linear correlation between [S100A8] and the monocyte count suggests that monocytes could be the main producers in the bone marrow microenvironment. No correlation was observed between [S100A8] and blasts nor with the neutrophil count. This hypothesis was reinforced by the particularly high rates of S100A8 observed in AML4 and AML5 of the French American British classification. S100A8 levels were significantly higher in AML with molecular abnormalities such as mutated *NPM1* or inv (16) of favorable prognosis. However, in the overall population, [S100A8] did not impact on remission rate, overall survival, or relapse rate. The cutpoint of 300µg/ml corresponding to the mean of S100A8 levels in AML was used to divide high and low expression of S100A8 in BM. The impact on prognosis was observed among mutated NPM1 and *FLT3*-ITD population for whom high levels of S100A8 were associated with significantly higher survival, compared to low S100A8 releasers.

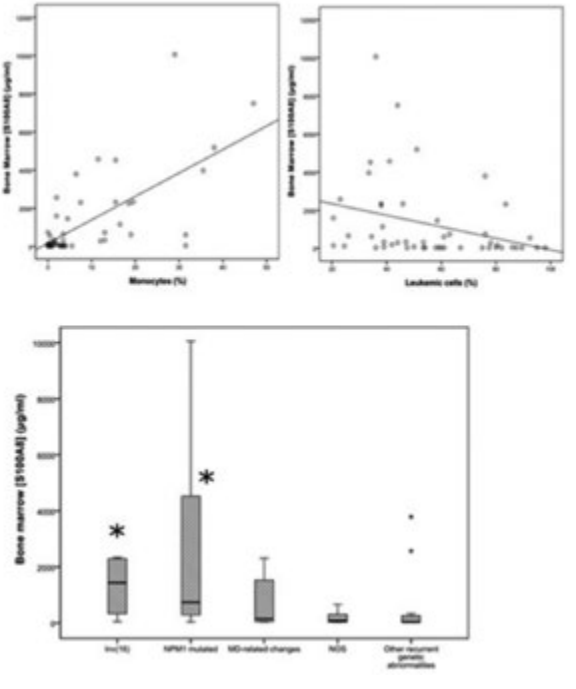

Figure 1.

Summary/Conclusion: In total, our study shows that there is a secretion of S100A8, probably of monocytic inflammatory origin, depending on the molecular status of patients that contributes to their prognosis.

PB1703

IMPROVING RISK STRATIFICATION IN ACUTE MYELOID LEUKEMIA WITH MRNA TECHNIQUES: BAALC AND WT1 LEVELS AFTER INDUCTION ARE BETTER THAN MORPHOLOGIC STATUS POST INDUCTION AND CYTOGENETIC AT DIAGNOSIS

C. Rodríguez Medina[1,*], Y. Florido Ortega[1], E. González Pérez[2,]
C. Bilbao Syero[1], R. Fernandez Martin[3], N. Cruz Cruz[1], M.D.L.N. Saenz Perdomo[1], S. Jimenez Bravo de Laguna[1], M.T. Gómez Casares[1,]
T. Molero Labarta[1]

[1]Hematology, Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, [2]Hematology, HUGC Dr Negrin, Las Palmas, [3]Hematology, Hospital Insular de Gran Canaria, Las Palmas de Gran Canaria, Spain

Background: AML is a heterogeneous disease in whom cytogenetic (CG) and ages at the moment of diagnosis are the best prognostic variables and both of them are the basis for adapted therapy protocols. However, the morphologic response and MRD status by MFC after chemotherapy are too powerful variables.
Aims: To compare, retrospectively, the powerful of the CG at the moment of diagnosis, morphologic status after induction and changes in mRNA levels of genes WT1 and BAALC between diagnosis and post induction
Methods: We design a retrospective study with AML patients and intermediate CG (ELN 2010 criteria) treated with at least one cycle of intensive chemotherapy and morphologic status evaluated. Patients with all other CG or exitus in induction were excluded. Patients treated in Hospital Dr Negrín between 2004-17 and Hospital Insular Gran Canaria 2010-2016 were included. Morphological response was according to Cheson's criteria with a dichotomous approach: Complete response (CR) or not. Gene expression levels were studied in bone marrow specimen at the diagnosis and after first induction cycle. The study was performed with real time qPCR with Light Cycler 480. The changes in expression level was considered for each patient and was selected a cut-off point of 95% decrease between the two study moments.
Results: Our series consisted of 112 patients, 60.7% males and 39.3% females. Median age was 58 (R 16-77). The overall survival (OS) of the entire cohort hat a median of 26 months (CI95% 19.8-32.3). Distribution for intensification treatment approaches: Allogenic transplant (Alo) 35.8%, high dose chemotherapy, including auto transplant (Chemo) 35.8%, not receive or hipomethilating agents 28.4%, with a median OS: NR, 24 m and 12 m respectively with p<0.001. Global rate CR after first cycle was 62.5%. Median OS according to morphologic response was 38 m for CR (CI95% 4.8-71.1) and 16 m for non CR group (CI95% 8.4-23.5) with p=0.005. Total number of patients with gene expression study between diagnosis and post induction was 54 with 58 lost cases. Of valid cases, 60% achieved a decrease greater than 95% in their levels of expression. Median OS was 13 m (CI95% 6.2-19.7) and Non reached (NR) for those with better response with p<0.001. In patients without CR, the gene expression study was available for 14 cases. However 43% achieved a greater than 95% reduction in their levels. The median OS for those patients was NR and 7 m (CI95% 0.7-13.9) for low decliners with p=0.011. Considering intensification treatment, patients with greater decrease in expression, the median OS was NR for Alo and Chemo group, without significant difference, meanwhile in those with low decrease in gene expression the median OS for Alo group was 38 m (CI95% 17.1-58,8) and 11 m (CI95% 8.4-13.5) for chemo but without significance.

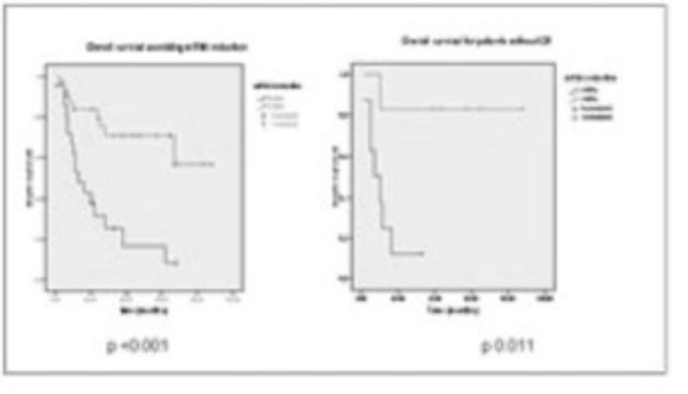

Figure 1.

Summary/Conclusion: 1) A decrease greater 95% in expression levels of genes WT1 or BAALC between diagnosis and post induction chemotherapy, was able to identify patients with greater probability of survival than the morphological response achieved after induction and the CG at diagnosis. Even in patients without CR, was able to separate patients into groups with significant survivals difference. 2) A decrease greater 95% in expression levels of genes WT1 or BAALC allowed identify patients with a good sensibility to chemotherapy and special good prognosis (>65% OS) in whom intensification with Alo would not provide benefit.

PB1704

FREQUENCY OF GENE MUTATIONS IN A COHORT OF COLOMBIAN PATIENTS WITH ACUTE MYELOID LEUKEMIA BEFORE AND AFTER INDUCTION TREATMENT

A. Cardona[1], J. Prada-Arismendy[1,*], E. Castillo[2], W. Castellanos[3], M.I. Hernández-Estrada[4], J. Machado[4]

[1]Grupo de Investigación e Innovación Biomédica, Instituto Tecnológico Metropolitano, Medellín, [2]Unidad de Oncología y Hematología Clínica, Hospital Manuel Uribe Ángel, Envigado, [3]Unidad de Hematología, Clínica Somer, Rionegro, [4]Facultad de ciencias exactas y aplicadas, Instituto Tecnológico Metropolitano, Medellín, Colombia

Background: Mutations that are associated with AML have a high impact on the prognostic of patients, and certain genetic profiles may guide an adequate therapeutic strategy. In Colombia, there are no data on the frequency of mutations associated with this neoplasm.
Aims: To describe the frequency of mutations in a cohort of patients with AML and how they can be related to the response to induction therapy.
Methods: Blood samples were collected from 27 AML patients before and after treatment induction during 2015-2017. Written informed consent was obtained at Hospital Manuel Uribe Angel and Clínica Somer. 500 ng of DNA were used to detect mutations in eight genes related to AML pathogenesis through a customized qBiomarker Somatic Mutation PCR array. For statistics analysis, *R* v.3.4.3 was used. Patient outcome was modeled using multinomial regression models including molecular and clinical data. Analyses on mutation associations were conducted with logistic regressions. Odds ratio (OR) were determined for regression coefficients and p-values with a Z-Wald test.

Table 1.

Gene	Domain	Mutation type and number (localization)	Patients carrying at least one mutation (Before n=27; after n=21)	
			Before (%)	After (%)
CEBPA	DNA binding and dimerization	3 insertions (p.K304, p.K313)	1 (3.7)	0
DMT3A	Methyltransferase	1 substitution (p.R882)	1 (3.7)	1 (3.7)
FLT3	Yuxtamembrane	2 substitutions, 5 ITDs	7 (25.9)	1 (3.7)
	2nd Tyrosine kinase	4 substitutions (p.D835)		
IDH1	IMDH conserved	5 substitutions (p.R132)	1 (3.7)	1 (3.7)
IDH2	IMDH conserved	2 substitutions (p.R140, p.R142)	6 (22.2)	6 (22.2)
NPM1	Nucleolar localization signal	7 frameshifts (p.W288)	1 (3.7)	1 (3.7)
NRAS	GTP binding	6 substitutions (p.G12, p.G13, p.Q61)	13 (48.1)	7(48.1)
KIT	2nd Tyrosine kinase	3 substitutions (p.D816,)	3 (11.1)	0

Results: The total number of patients was 27, which were followed for an average of 7 months. Thirteen patients (48,14%) were women and 14 were men (51.85%); age range was 18-78 y (mean 49.9 y). Twenty-one patients survived (77.7%), while 6 died during or after induction treatment (22.3%). Before treatment, the most frequent mutation was NRAS c.35G>A (22.22%), followed by IDH2 c.515G>A (14.81%). After treatment, IDH2 c.515G>A was the most frequent mutation (14.8%), while NRAS c.35G>A corresponded to 11.11%. In 8 patients (29.6%), we found 8 persistent mutations after treatment; curiously all patients (n=4) who had mutation in IDH2 c.515G>A persisted with it after treatment. The logistic regression analysis determined a higher relative risk trend of presenting AML-M1 in patients with FLT3, NRAS or IDH2 mutations. Mutated NRAS and IDH2 after treatment were highly associated with presenting the respective mutation at diagnosis. Multinomial models describing the outcome (death, refractoriness, partial response and complete response) based on molecular and clinical variables suggested -for this cohort of patients-, that mutated FLT3, IDH2 or NRAS after treatment confers a lower OR for death outcome *versus* complete response. Furthermore, age (OR: 0.56: p=0.0000025) and blast percentage at diagnosis (OR: 0.69: p=0.0002645) were inversely associated with complete response compared with patients who died. On the other hand, mutations before treatment in FLT3 were associated with a lower OR in refractoriness or partial response *vs* complete response. Finally, mutations in NRAS after treatment had a lower OR in relation to partial response *vs* complete response. Results regarding mutations are contradictory to what was previously published, nevertheless, the cohort size and a follow-up of only 7 months could have impacted on results reported here.
Summary/Conclusion: We are preliminarily describing the frequency of mutations of a cohort of AML patients in Colombia. Contrary to the literature, we found a high frequency of mutations in *IDH2* and *NRAS* genes, while *FLT3* remains as one of the most frequently mutated genes, being FLT3-ITD the most common in our cohort. It is interesting that mutations in IDH2 do not disappear after treatment. In sum, the present work describes gene mutations not previously described in AML Colombian patients. It is necessary to amplify the size of the cohort and to continue the follow-up of patients to observe adverse results that could be correlated with the presence of some mutations.

PB1705

SRSF2 GENE MUTATIONS ARE ASSOCIATED WITH TP53Γ EXPRESSION LEVELS AND OVERALL SURVIVAL IN PATIENTS WITH ACUTE MYELOID LEUKEMIA (AML)

K. Matiakowska*, A. Bartoszewska-Kubiak, E. Bielinska, M. Morgut-Klimkowska, O. Haus

Department of Clinical Genetics, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz, Poland

Background: Acute myeloid leukemia (AML) is a heterogeneous clonal disorder with a presence of diverse genetic abnormalities in hematopoietic stem cells. *SRSF2* encodes serine/arginine-rich splicing factor 2, important for splice-site selection, spliceosome assembly, constitutive and alternative splicing. More than 90% of human genes undergo alternative splicing to make various protein isoforms. *TP53* gene, that encodes a tumor suppressor protein, may be translated into 13 different isoforms due to alternative splicing. Alternative splicing of its intron 9 can produce 2 different proteins: p53β and p53γ, without oligomerization domain (stop codon is localized in exon 9b).
Aims: The aim of the study was to assess mutational status of *SRSF2* as well as *TP53β* and *TP53γ* expression levels in association with hematological and clinical features of patients with AML.
Methods: 49 AML patients with normal karyotype were included in the study. *SRSF2* gene mutations in codon 95 were analyzed by direct sequencing. *TP53*β and *TP53γ* expression levels were assessed with real time PCR. Expression levels were analyzed with ΔΔCt method, with *ABL* as a control gene and K562 cell line as a calibrator.
Results: *TP53β* and *TP53γ* transcripts were detected in all patients. 5 patients carried mutation in *SRSF2*. Mutation status of *SRSF2* had no statistical significance to overall survival (p=0,36). Assessed median expression level was much higher for *TP53β* than *TP53γ* (ΔΔCt 44,04 *vs* 9,42, respectively; p<0,05). Furthermore, expression level of *TP53γ* was significantly associated with *SRSF2* mutations (p=0,021); patients with mutation had lower expression level. Patients were also classified into two groups, according to median expression value of *TP53*: with overexpression or with low expression of *TP53β/γ*. Kaplan-Meier estimation showed statistically significant difference in overall survival between the groups-longer for patients with overexpression of *TP53γ* isoform (p=0,03).
Summary/Conclusion: The above results may suggest a clinical importance of simultaneous analysis of *TP53* isoform expression and *SRSF2* gene mutations. It may be hypothesized that a changed sequence of the *SRSF2* gene regulates *TP53γ* expression and, as a consequence, regulates the cell cycle and overall survival.

PB1706

ACUTE MYELOID LEUKAEMIA (AML) PATIENTS WITH CO-EXISTING T(8;21) AND TRISOMY 4 ABNORMALITIES

L.C. Lau[1,*], Y.C. Linn[2], S.T.A. Lim[1], S.L. Tien[2]

[1]Molecular Pathology, [2]Hematology, Singapore General Hospital, Singapore, Singapore

Background: The t(8;21) rearrangement is closely associated with AML-M2 and is often co-detected with deletion 9q, and loss of the sex chromosomes. This abnormality is associated with a favourable prognosis. On the other hand, its coexistence with trisomy 4 is uncommon and the clinical significance is unclear.
Aims: To highlight the disease course of two patients with AML harbouring a co-existing t(8;21)(q22q22) and trisomy 4 abnormality.

Methods: Bone marrow cells were cultured at 37^{O}C for 24 and 48hrs and cells from both samples were harvested as per standard protocol. Cytogenetic analysis was carried out on G-banded metaphase cells.
Results: Both patients had trisomy 4 in addition to a t(8;21) rearrangement in the first patient and a t(8;10;21)(q22;q24;q22) rearrangement in the second patient. c-KIT exon 17 mutation was detected in both patients. The first patient achieved complete remission after 35 days of induction. However, the patient relapsed after 5 months of myeloablative haemotopoietic stem cell transplant (HSCT). A more complex 47,XX,t(3;10)(p21;q24),+4,t(8;21)(q22;q22) karyotype was obtained. Disease progression was evidenced by the additional abnormality. The patient achieved complete remission in the marrow after a complicated course of chemotherapy. After nine months of HSCT, the second patient developed granulocytic sarcoma in the sternum. He achieved remission and the marrow showed a normal karyotype and all cells were of donor origin after one year of treatment.
Summary/Conclusion: To our knowledge, there are only 4 reported cases of AML with co-existing t(8;21) and trisomy 4 in the Asian population. No detailed cytogenetic investigation and treatment regimens were reported by these authors. Our first patient had a slow response to treatment and a rapid relapse with disease progression despite early ablative HSCT at first remission. The second patient developed granulocytic sarcoma after the HSCT. From the observation of these two patients, the presence of the trisomy 4 may define a unique subtype of AML with t(8;21)(q22;q22). Such patients should be monitored closely for risk of relapse. c-KIT mutation has been shown to confer drug resistance. Treatment with novel therapy inhibiting KIT tyrosine kinase activity may be of potential value.

PB1707

PECULIARITIES OF IMMUNOLOGICAL INDICATORS IN ACUTE MYELOBLASTIC LEUKEMIA IN DYNAMICS

O. Smirnova*, E. Kasparov

Research Institute of Medical Problems of the North FIC KSC SB RAS, Krasnoyarsk, Russian Federation

Background: Acute myeloblastic leukemia is a severe onco-hematologic disease. Reducing the reactivity of the patient's immune system is one of the provocative mechanisms in its progression.
Aims: The purpose of this study was to study the dynamics of the subpopulation composition of lymphocytes in the blood in patients with acute myeloblastic leukemia (AML).
Methods: In the study group there were 100 AML patients, in the acute debut stage-30 patients, in the stage of complete remission after the treatment-49 patients, in the stage of repeated relapse-21 people. For the stage of acute debut, the first manifestation of the disease with the number of blasts in the bone marrow is 25% or more. Complete remission after treatment in patients was diagnosed with detecting in the myelogram of not more than 5% of blast cells with normal cellularity, in the cerebrospinal fluid there were no leukemia cells. Repeated relapse was detected when more than 25% of the blasts were detected in the bone marrow indices after the remission achieved before. The control group consisted of 125 practically healthy volunteers. BD MultiTEST test systems with a 4-color antibody panel: CD3 / CD8 / CD45 / CD4 and CD3 / CD16 + CD56 / CD19, labeled with fluorochromes FITC, PE, PerCP and APC, were used to estimate the relative content of lymphocyte subpopulations. To calculate the absolute content of subpopulations, the absolute number of lymphocytes obtained from the blood test on the hematological analyzer Cell Dyn1800 (Abbott, USA) was used. Student t-test, non-parametric Mann-Whitney criterion U, and linear correlation coefficient r were used for statistical data processing.
Results: The state of the cell link of immunity in patients with the M2 variant of AML during primary attack is characterized by a decrease in the relative number of pan-markers of T-lymphocytes and T-helpers, which indicates not only the development of an immunodeficiency state, but also the inferiority of the T-helper link, leading to inefficiency and cellular, and humoral units of immunity. At the stage of complete remission, leukopenia, a decrease in the relative and absolute indices of the T-cell link of immunity, NK cells, and B-lymphocytes with violation of activation processes are revealed. With repeated relapse of AML, the state of cellular immunity manifests itself in the form of leukopenia, lymphopenia, a decrease in the relative and absolute indices of the T-cell link of immunity, NK cells, and B-lymphocytes with disruption of activation processes.
Summary/Conclusion: At the stage of acute debut and remission of AML, T-cell immunodeficiency develops, at the stage of repeated relapse-combined immunodeficiency with defeat of T- and B-systems of immunity. A feature of AML is the depletion of NK cells, which contributes to the progression of the disease and the development of relapse.

PB1708

DYNAMICS OF METABOLIC INDICATORS OF ACUTE NON-LYMPHOBLASTIC LEUKEMIA

O. Smirnova*, E. Kasparov

Research Institute of Medical Problems of the North FIC KSC SB RAS, Krasnoyarsk, Russian Federation

Background: Acute myeloblastic leukemia is a severe onco-hematologic disease. The functioning of the immune system depends on the characteristics and severity of metabolic processes in its cells. Enzymes of oxidation-reduction reactions are used to evaluate biochemical processes in lymphocytes, because they realize the basic reactions of intracellular metabolism and are responsible for combining all metabolic exchanges.
Aims: The purpose of this study was to study the dynamics of the mechanisms of metabolic status of lymphocytes in the blood in patients with acute myeloblastic leukemia (AML).
Methods: In the study group there were 100 AML patients, in the acute debut stage-30 patients, in the stage of complete remission after the treatment-49 patients, in the stage of repeated relapse-21 people. The control group consisted of 125 practically healthy volunteers. Bioluminescent determination of the activity of NAD (P) -dependent dehydrogenases was carried out on the biochemiluminometer BLM-3607. This method was used to determine the activity of the following enzymes: glucose-6-phosphate dehydrogenase, glycerol-3-phosphate dehydrogenase, malic enzyme, NAD- and NADH-dependent lactate dehydrogenase reaction, NAD- and NADH-dependent reaction of malate dehydrogenase, NADP- and NADPH-dependent glutamate dehydrogenase, NAD-and NADH-dependent glutamate dehydrogenase, NAD- and NADP-dependent isocitrate dehydrogenases and glutathione reductase. Activity of dehydrogenases in blood lymphocytes was expressed in enzymatic units (1 E=1μmol / min) per 104 cells). Based on the results of the research, a database was created in MS Excel 2000 spreadsheets, on the basis of which statistical analysis was carried out using descriptive statistics methods with Student's t-criterion, nonparametric using exact Mann-Whitney criteria using the Statistica 8.0 application software package.
Results: When studying the features of the metabolic status of blood lymphocytes in patients with a primary AML attack, a decrease in the activity of LDH aerobic reaction is revealed. The decrease in the intensity of terminal glycolysis reactions and the level of concentration of intermediates for the Krebs cycle is proved by the revealed decreased activity of LDH and NADH-LDH. The level of reaction of the Krebs cycle of NADP-dependent isocitrate dehydrogenase in patients at the acute debut stage relative to control is decreased. In patients in the stage of complete remission of AML, the activity of the NADH-LDH enzyme is restored, while the activity of the LDH enzyme remains reduced. When studying the metabolic status of patients with the M2-variant AML in a repeated relapse, a decrease in the transfer of lipid catabolism products to the redox-oxidative reactions of glycolysis is revealed, due to a decrease in the activity of G3PDH. The decrease in glycolysis activity leads to its inhibition, which is confirmed by the decreased activity of the anaerobic LDH reaction. The activity of NADH-LDH is decreased. The activity of aerobic LDH reaction in lymphocytes was reduced. However, in patients with AML at the stage of recurrence, the activity of glutathione reductase is restored.
Summary/Conclusion: At all stages of AML, a marked decrease in the intensity of intracellular metabolic processes of lymphocytes is observed, mitochondrial transport, glycolysis, and metabolism in the lemon cycle decrease. A feature of acute debut and remission of AML is the reduction of peroxide processes in lymphocytes. With repeated relapse, peroxide processes in lymphocytes are restored; however, intracellular lipid catabolism decreases.

TO IDENTIFY PROGNOSTIC BIOMARKER AND GENE REGULATION BY TCGA DATASET: ALDH1A1 IN ACUTE MYELOID LEUKEMIA

H. Yi[1,*], X. Su[2], R. Deng[1], F. Fan[1], H. Sun[1], G. He[1], S. Lai[1], Y. Su[1]

[1]Hematology, Chengdu General Hospital, Chengdu, [2]Children's Heart Center, Institute of Cardiovascular Development and Translational Medicine, Wenzhou, China

Background: Identify prognostic biomarker is benefit to acute myeloid leukemia (AML) stratification and making individual therapeutic strategies.
Aims: We try to demonstrated the prognostic biomarker of acute myeloid leukemia (AML) and gene regulation pattern.
Methods: We analyzed general clinical information of AML, detected prognostic impact and gene regulation pattern of ALDH1A1 from The Cancer Genome Atlas (TCGA) dataset.

Results: The most highly incident rate of AML patients was at sixties'. More than half of patients were intermediate risk by NCCN stratification. Fms-like tyrosine kinase-3 (FLT3) was the most frequent mutation gene. Patients less than 60 years old and M3 type in French-American-British (FAB) classification were independent favorable prognostic factors, but not the gender, peripheral or bone marrow blast count, white blood cell count, hemoglobin concentration or platelet count. The expression of ALDH1A1 was associated with risk stratification and could be as a prognostic impact biomarker in AML. Knocking down ALDH1A1 affected leukemia cell survival and self-renewal property. The expression of ALDH1A1 was correlated to the expression of ITGB3 and could be regulated by integrin αvβ3.
Summary/Conclusion: Our study demonstrated TCGA is a high fidelity dataset for AML research and ALDH1A1 is a prognostic factor which could be regulated by integrin αvβ3.

PB1710

CHROMOSOMAL ABNORMALITIES IN PAKISTANI PATIENTS WITH ACUTE MYELOID LEUKEMIA

M.S. Shaikh*, Z. Ahmed

Aga Khan University, Karachi, Pakistan

Background: The heterogenous response to treatment in acute myeloid leukemia (AML) can be attributed largely to the difference in cytogenetic features identified in between cases. Cytogenetic analysis in acute leukemia is now routinely used to assist patient management, particularly in terms of diagnosis, disease monitoring, prognosis and risk stratification. Knowing about cytogenetic profile at the time of diagnosis is important in order to take critical decisions in management of these patients.
Aims: The study was conducted to determine the distribution of cytogenetic abnormalities in Pakistani adult patients with AML in order to have insights regarding behavior of the disease.
Methods: A retrospective analysis of all the cases of AML (≥15years old) diagnosed at Aga Khan University from January 2011 to December 2016 was performed. Cytogenetic analysis was made for all cases using the trypsin-Giemsa banding technique. Karyotypes were interpreted using the International System for Human Cytogenetic Nomenclature (ISCN) criteria.
Results: A total of 321 patients were diagnosed with AML during the study period, of which 288 samples successfully yielded metaphase chromosomes. The male to female ratio was 1.7:1. A normal karyotype was present in 61% (n=176) of the cases whereas, 39% (n=112) had an abnormal karyotype. Of the abnormal cases, t(8;21)(q22;q22) and t(15;17)(q22;q12) were identified in 8.3% and 4.9% cases respectively. Adverse prognostic cytogenetic subgroups including complex karyotype, monosomy 7 and t(6;9)(p23;q34) were identified in 9%, 1% and 0.7% patients respectively.
Summary/Conclusion: This largest cytogenetic data in adult AML from Pakistan showed comparable prevalence of favorable prognostic karyotype to international data. The prevalence of specific adverse prognostic karyotype was low.

PB1711

SUCCESSFUL COVERAGE OF DIFFICULT TO SEQUENCE GENES (CALR, CEBPA, AND FLT3) ASSOCIATED WITH MYELOID DISORDERS USING A HYBRIDISATION-BASED ENRICHMENT APPROACH PRIOR TO NEXT-GENERATION SEQUENCING (NGS)

L. Georgieva*, E. Uddin, J. Chan, G. Speight

Oxford Gene Technology, Begbroke, United Kingdom

Background: The application of short read NGS for research into myeloid disorders such as myeloproliferative neoplasms (MPNs) and acute myeloid leukaemia (AML) has been hampered by the inability to sequence certain genes. These genes can harbour key mutations so it is desirable to ensure suitable sequencing coverage is obtained. These genes amongst others include: *CALR* exon 9 insertions and deletions (up to 52 bp), *CEBPA* single nucleotide variants (SNVs) and *FLT3* Internal Tandem Duplications (ITDs) and SNVs. Each of these regions contain certain challenging DNA sequences that can impact the quality of the data generated, *e.g.* large indels and low complexity regions (*CALR*), high GC content (75% on average for the whole gene with specific regions at 100%) and repetitive regions (*CEBPA*), and complex repetitive elements (*FLT3*).
Aims: To determine whether a hybridisation-based enrichment approach overcomes the difficulties associated with these genes, and permits the generation of high quality (sufficient de-duplicated depth) data to allow these targets to be accurately interrogated.
Methods: We utilised a hybridisation-based enrichment approach for library preparation in combination with a SureSeq myPanel™ NGS Custom AML panel. The library was then sequenced using a 2x150 bp read length protocol on an Illumina MiSeq®.
Results: Here we present the coverage and variants generated from numerous research samples for each of these difficult to sequence genes. The results clearly show that this approach can reliably detect and accurately size (including low allele frequency) insertions and deletions of up 52 bp in *CALR* (exon 9), SNVs and deletions in *CEBPA* with a de-duplicated depth in excess of 2000x as well as ITDs of between 24 and 201 bp in *FLT3*.
Summary/Conclusion: This approach is suitable for the analysis by NGS of these difficult genes and therefore removes the requirements for supplementary approaches to analyse these difficult genes, such as Sanger sequencing (*CEBPA*) and fragment analysis (*CALR* and *FLT3*).

PB1712

MUTATIONAL LANDSCAPE OF ACUTE MYELOID LEUKEMIA WITH NORMAL CYTOGENETICS IN ROMANIAN PATIENTS-A TARGETED NEXT GENERATION SEQUENCING PRELIMINARY REPORT

A. Arghir[1,2,*], S.M. Papuc[2], D.-S. Soare[1,3], E. Radu[1,3], I. Ciocănea-Teodorescu[2], V. Popov[4], M. Găman[1,3], C. Marinescu[1,3], A. Nicolescu[3], R. Colesniuc[2], M. Murat[4], M. Popescu[4], O. Patrinoiu[4], M. Andreescu[4], N. Berbec[1,5], S. Angelescu[1,5], D. Cîşleanu[1,3], A.-M. Vlădăreanu[1,3], H. Bumbea[1,3]

[1]Carol Davila University of Medicine and Pharmacy, [2]Victor Babes National Institute of Pathology, [3]Emergency University Hospital, [4]Colentina Clinical Hospital, [5]Coltea Clinical Hospital, Bucharest, Romania

Background: Acute myeloid leukemia (AML) is a complex and dynamic disorder characterized by a wide range of recurrent driver genetic defects. The introduction of next generation sequencing (NGS) in AML genome investigation led to a better understanding of the mutational spectrum intricacy. Characterization of the patterns of mutation co-occurrence has become equally significant, as most AML patients bear more than one driver mutation. The functional consequences and clinical relevance of mutations and patterns of co-mutation are not fully understood, thus further studies are needed in order to inform clinical practice.
Aims: We report on the results of targeted NGS and fragment analysis for characterization of the mutational landscape in a group of 12 Romanian AML patients with normal cytogenetics (NC-AML).
Methods: Targeted NGS testing with Ion AmpliSeq™ AML Research Panel (ThermoFisher Scientific) was performed on genomic DNA extracted from diagnostic bone marrow samples according to manufacturer's recommendations. Nineteen genes were targeted for entire coding regions (*CEPBA, DNMT3A, GATA2, TET2, TP53*) or mutational hotspots (*ASXL1, BRAF, CBL, FLT3, IDH1/2, JAK2, KIT, KRAS, NRAS, NPM1, PTPN11, RUNX1, WT1*). Ion PGM System (ThermoFisher Scientific) and NextGENe v.2.4.2.1 (SoftGenetics) were used for sequencing and data analysis. Internal tandem duplication of FLT3 gene (FLT3-ITD) were assessed by PCR amplification of exons 13 and 14 and the spanning intronic region of the *FLT3* gene. The amplified products were analysed by automated electrophoresis on the 2100 Bioanalyzer system (Agilent Technologies).
Results: A total of 38 mutations, with a median of 3 mutations per patient (ranging from 2 to 5 mutations/patient), were identified in our patient group. Among these, 31 were driver mutations recurrent in myeloid malignancies, while 7 mutations, with *in silico* predicted deleterious effects, were not previously reported in cancer databases (COSMIC, ClinVar). The highest mutation frequency was observed for *NPM1*, as previously reported in NC-AML, followed by *DNMT3A* gene. The mutation co-occurrence patterns in our patient group followed the previously reported ones, however some uncommon association were observed, such as between *NPM1* and *NRAS*Q61. None of the investigated patients showed *FLT3-ITD*. However, two patients presented *FLT3-TKD* point mutations in association with *NPM1* mutations.
Summary/Conclusion: Targeted NGS combined with fragment analysis proved a successful approach for molecular profiling of NC-AML highlighting the complexity of the molecular profiles in this AML subgroup. The study represent one of the first NGS analyses of Romanian patients with NC-AML. The mutational data obtained in our patients are consistent with previously published data, while also revealing new insights, such as previously unreported variants or new mutational associations. The data contribute to a better understanding of the mutational landscape of AML and, ultimately, to an improved patient care.

INVESTIGATING THE EFFECT OF C-MYC PROTO-ONCOGENE INHIBITION IN ACUTE PROMYELOCYTIC LEUKEMIA

M. Sayyadi*, N. Riyahi, N. Sheikh-Zeineddini, D. Bashash

Department of Hematology and Blood Banking, School of Allied Medical Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic Of

Background: The c-Myc proto-oncogene, an important regulator of cell proliferation, is amplified in many tumor types and has been linked to both the development and progression of a wide range of human cancers spanning from solid tumors to leukemia. Interest into c.Myc targeted therapy has elevated by the intertwining between acquisition of chemoresistant phenotype and the aberrant expression of c.Myc in leukemia patients.
Aims: This study was aimed to investigate the anti-cancer effects of 10058-F4, a potent small-molecule inhibitor of c-Myc, in acute promyelocytic leukemia (APL).
Methods: APL-derived NB4 cells were subjected to the increasing concentrations of 10058-F4 and then, the cytotoxic effect of the inhibitor was studied using trypan blue, Annexin/PI, MTT, caspase-3 activity, and BrdU cell proliferation assays. Moreover, gene expression analysis by using quantitative real-time PCR was applied to investigate the molecular mechanisms of action of 10058-F4.
Results: We found that the cytotoxic effects of the inhibitor, as revealed by the decreased cell viability and metabolic activity, were mediated through induction of apoptotic pathway in NB4 cells. The resulting data also outlined that inhibitor-induced apoptosis was accompanied by the elevated Bax/Bcl-2 molecular ratio and the enhanced augmentation of caspase-3 activity. Moreover, we found that abrogation of c.Myc using 10058-F4 resulted in a considerable increase in the mRNA expression levels of cyclin-dependent kinase inhibitors p21 and p27, which was in agreement with the induction of G1 cell cycle arrest in APL-derived NB4 cells.
Summary/Conclusion: The present study revealed that c-Myc inhibition using a potent small-molecule inhibitor affects multiple cellular activities in NB4 cells and represents a novel promising anti-leukemic approach in APL treatment.

KARYOTYPE COMPLEXITY AND CHARACTERIZATION OF CHILDHOOD ACUTE MYELOID LEUKEMIA (AML) IN PAKISTAN

Z. Ahmed[1,*], M.S. Shaikh[2], A. Nasir[2], S. Alatf[3], Z. Fadoo[3], T. Moatter[2]

[1]Pathology and Laboratory Medicine, Aga Khan University, [2]Pathology and Laboratory Medicine, [3]Pediatric Oncology, Aga Khan University Hospital, Karachi, Pakistan

Background: Acute myeloid leukemia (AML) is a heterogeneous disease. Based on cytogenetics findings, AML patients are stratified into three major risk categories: favorable, intermediate and unfavorable. For the intermediate risk category, it has been difficult to stratify prognostically due to the clinical heterogeneity and scarce knowledge of the molecular alterations underlying in childhood AML subgroup. Knowing about cytogenetic profile at the time of diagnosis is important in order to take critical decisions in management of these patients.
Aims: To determine and characterize cytogenetic abnormalities in Pakistani pediatrics patients with AML
Methods: A retrospective review of all the cases of AML (≤15years old) diagnosed at Aga Khan University from January 2011 to December 2016 was performed. Cytogenetic analysis was made for all cases using the trypsin-Giemsa banding technique. Karyotypes were interpreted using the International System for Human Cytogenetic Nomenclature (ISCN) criteria.
Results: A total of 67 patients were diagnosed as AML during the study period with male to female ratio of 1.5:1. A normal karyotype was present in 45% (n=30) of the cases whereas, 55% (n=37) had an abnormal karyotype. Of the abnormal cases, t(8;21)(q22;q22) was identified in 15% cases. In poor prognostic group complex karyotype was 19%. Intermediate prognostic cytogenetic subgroups including structural anomalies (partial deletions and additions and translocations except deletion 7), trisomies were identified in 10% and 06% patients respectively
Summary/Conclusion: This study showed recurrent cytogenetic abnormalities in 55% Pakistani Children with AML. Favorable karyotypes, t(8;21)(q22;q22.1) was identified as the most prevalent specific chromosomal abnormality; the cumulative prevalence however was not significantly different in various age groups. This is in agreement with observations in international literature. Our data shows that the structural anomalies and complex karyotypes constituted the predominant unfavorable karyotype. To the best of our knowledge, this observation has not been reported before in Pakistani pediatrics patients with AML

BRIVANIB ALANINATE KILLS LEUKEMIC STEM CELL BY INHIBITING VASCULAR ENDOTHELIAL GROWTH FACTOR-2 AND FIBROBLAST GROWTH FACTOR RECEPTORS

S. Alikhani[1,*], S. Kaviani[2], S. Mohammadi[3], S. Alikhani[4]

[1]Hematology department, Faculty of medical sciences, Tarbiat modares university, [2]Hematology department, Faculty of medical sciences,Tarbiat modares university, [3]Hematology/oncology and stem cell transplantation research center, Shariati Hospital, [4]Biochemistry department, Pharmaceutical sciences branch, Islamic Azad University, Tehran, Iran, Islamic Republic Of

Background: Acute Myeloid Leukemia (AML) is a heterogenous, clonal hematopoietic malignancy with overproduction of abnormal myeloid progenitors in bone marrow. Although the 7+3 regimen for patients with AML has increased the survival rate, common chemotherapy is not very efficient especially for older patients and the possibility of relapsed and refractory is high which is due to malignant cell called leukemic stem cell. Hence, targeting overexpressed receptors like VEGFR-2 and its related signaling pathway in leukemic blasts is needed.
Aims: So, we aimed to evaluate the cytotoxicity of brivanib alaninate on AML cell lines by inhibiting VEGFR-2 and FGFR signaling pathways.
Methods: In this study, KG1a which has been considered as a drug resistance AML cell line and a leukemic stem cell model, was used for cell culture. Cells were treated with 5 different doses of Brivanib Alaninate (Apexbio company, USA) for 48 and 72 hours and then MTT assay (sigma-Aldrich) was performed to evaluate the viability of these cell lines. Optical densities of each wells were measured at 540 nm wavelength. Finally, annexin V FITC/PI staining to investigate apoptosis effects of Brivanib Alaninate.
Results: Viability of the cells at doses of 0.01, 0.1, 1, 10 and 100 M were 87, 82, 80, 73 and 71% after 48 hours and 75, 70, 65, 56 and 50% after 72 hours, respectively. The data showed that IC-50 of the drug is 100 M which was then confirmed with Flowcytometry. The flowcytometry results showed that 31.2% of cell are in late apoptosis and 20.4% of cells in early apoptosis state.
Summary/Conclusion: The effective dose of brivanib alaninate for treatment of KG1a cell line is 100 M with 50% cell death after 72 hours treatment. So, targeting two or more dominant signaling pathway and is suggested for target therapy and the use of brivanib alaninate in clinical trials for patients with AML especially in relapse state in recommended.

PB1716

MDR1 GENE DETECTED *in vitro* HAVE A PROGNOSTIC SIGNIFICANCE IN LEUKEMIA PATIENTS

M. Kolesnikova[1,*], A. Sen'kova[2], O. Berezina[1], M. Zenkova[2,]
T. Pospelova[1]

[11]Department for therapy, hematology and transfusiology of Novosibirsk State Medical University, Novosibirsk State Medical University, [22]Institute of Chemical Biology and Fundamental Medicine, Novosibirsk, Russian Federation

Background: Actual prognostic factors for testing acute leukemia are formed on detectable cytogenetic and molecular-genetic disorders, as well as initial data including the patient's age, leukocytosis, amount blast in the bone marrow. However, the study of genes of primary drugresistance or factors contributing to its development is not mandatory. Expression of the MDR1 gene by tumor cells is considered as one of the most common mechanisms of drugresistance.
Aims: The aim of this study was to assess the risk of developing drugresistance with acute leukemia patients based on MDR1 gene expression determination prior to initiation of therapy.
Methods: The study included 12 patients with acute lymphoblastic leukemia (ALL) and 25 patients with acute myeloblastic leukemia (AML). The average age of the patients was 47.9±15.7 years. Leukemia cells were taken from peripheral blood and bone marrow of patients. Assessment of multidrug resistance in tumor cells of leukemia patients was performed on bone marrow and/or peripheral blood samples using quantitative real-time reverse transcription-polymerase chain reaction (real-time RT-qPCR). RT-qPCR was used to evaluate the expression of the MDR1 gene. The results were normalized to GAPDH used as an internal standard. All statistical analyses were done with computer software MS Excel, OriginPro 7.5, Statistica 10.0.
Results: All leukemia patients were divided into groups with low, medium and high levels of expression based on the level of expression of MDR1. All leukemia patients were divided into groups based on their response to chemotherapy treatment (effectiveness of chemotherapy). For examination

of the chemotherapy effectiveness for acute leukemia patients was determined the number of blasts in the bone marrow after 1-2 chemotherapy courses. The intensive the expression level of the MDR1 gene is, the higher the risk of developing drugresistance is. Patients with AML have a moderate direct correlation ($r=0.66$, $p<0.05$) between the response to therapy and the expression of the MDR1 gene. In patients with ALL, a strong direct correlation was found ($r=0.77$, $p<0.05$) between response to therapy and expression of the MDR1 gene. Thus, patients with expressed expression of this gene should be classified as high risk, low level of expression and its absence-to a low risk group, and with moderate expression-to an intermediate risk group. In patients with high and moderate expression of the MDR1 gene, individual sensitivity to cytostatic drugs should be assessed for personalized correction of therapy regimens.

Summary/Conclusion: The data obtained demonstrate the importance of studying the expression level of the MDR1 gene with acute leukemia patients before initiating therapy to assess the prognosis of the disease.

DIFFERENTIAL GENE EXPRESSION PROFILE ALTERATIONS IN CHEMORESISTANT AML CELLS FOLLOWING THEIR EXPOSURE TO IDARUBICIN AND CYTARABINE

F. Kontsioti, E. Maratou, V. Mpakou, A. Bouhla, G. Stavroulaki, I. Glezou, E. Bazani, S. Papageorgiou, G. Dimitriadis, V. Pappa*

Second Department of Internal Medicine and Research Institute, Attikon University General Hospital, Athens, Greece

Background: Acute myelogenous leukemia (AML) is the most common malignant myeloid disorder in adults. Relapses are initiated by chemoresistant leukemic cells. DNA damage and repair mechanisms influence not only the genetic predisposition to leukemia but are also very important for refractoriness to treatment.

Aims: The aim of this study was to investigate the possible alterations in the gene expression profile in DNA damage signaling pathways and apoptosis in two leukemic cell lines following their exposure to chemotherapeutic agents, idarubicin and cytarabine.

Methods: Kasumi-1 and MV4-11 AML cells were treated with either idarubicin (0.1μM) for 6h or cytarabine (1μM) for 48h. Apoptosis was determined through FACS(Annexin 5/7AAD). Statistics were performed through One Way Anova analysis. Dead cells were eliminated from drug- treated cells through the appropriate commercial kit. Gene expression profiling through PCR arrays analysis (RT^2Profiler,Qiagen)was performed after RNA extraction from untreated, total drug-treated and chemoresistant (live)cells. Human DNA Damage Signaling pathway related genes' expression was evaluated and analyzed through RT^2Profiler PCR Array data analysis tool.

Results: Kasumi-1 and MV4-11, idarubicin- and cytarabine- treated cells presented with enhanced apoptosis compared to untreated cells. PCR Array analysis after idarubicin treatment of total Kasumi-1 cells revealed a significant up-regulation of genes involved in apoptosis(BBC3), cell cycle(CDKN1A, PPP1R15A), DNA damage and repair(PNP), and ATM/ATR signaling (RBBP8) while Cytarabine treatment led to the up-regulation of an even greater number of genes (involved mostly of the DSB repair pathway *i.e.* HUS1,MLH1,NBN,XRCC1,XRCC2). Interestingly, significant differences in their gene expression patterns were observed between total cytarabine-treated Kasumi-1 cells and chemoresistant ones. HUS-1 gene (DSB) was up-regulated in cytarabine-treated cells and down-regulated in chemoresistant cells, while MLH1 and NBN genes presented the opposite pattern. Cytarabine treatment of total MV4-11 cells led to an up-regulation of genes involved in cell cycle(CDKN1A,TP73), DNA damage repair(GADD45A), including DSB repair(H2AFX) and NER(PCNA). Idarubicin also led to the up-regulation of a significant different panel of examined genes. Most importantly, PPP1R15A gene's expression in both cytarabine and idarubicin chemoresistant MV4-11 cells was significantly up-regulated compared to drug treated cells.

Summary/Conclusion: Our data demonstrate that both idarubicin and cytarabine result in enhanced cell death of Kasumi-1 and MV4-11 cells. In terms of DNA damage related genes' expression, both agents seem to affect a large number of genes involved in various mechanisms, mostly leading to their up regulation, in both cell lines. Most importantly, our data suggest differences in the gene expression pattern between chemoresistant cells and drug-treated cells, indicating the significance of DNA damage and repair pathways involved in chemoresistance. Specifically, the up-regulation of PPP1R15A gene in chemoresistant MV4-11 cells after treatment with both agents is of great importance since this gene participates in cell cycle and its transcript levels are increased following stressful growth arrest conditions and treatment with DNA-damaging agents. Considering that MV4-11 cell line is an AML chemoresistant one, up-regulation of the expression of PPP1R15A gene which facilitates recovery of cells from stress is totally compatible. Our results need to be further confirmed in AML patients with the view to design more effective treatments.

Background: Induction treatments for acute myeloid leukemia (AML) patients are based on the combination of Cytarabine (CYT) and one anthracycline, mainly Idarubicin (IDA), Daunorubicin (DNR), or Mitoxantrone (MIT). The choice of the anthracycline employed has been widely studied in multiple clinical trials showing similar CR rates, with some exceptions in which IDA reported higher CR. A new Personalized Medicine (PM) test developed by Vivia Biotech, based on an actionable native environment method which enables the establishment of pharmacological responses in *ex vivo* patient samples, is uncovering individual responses to these treatments.
Aims: Our objective is to explore whether a significant percentage of individual patients may respond differently to IDA *vs* DNR *vs* MIT treatments, in spite that of their "on average" similar response shown by clinical trials.
Methods: Bone marrow (BM) samples were collected at diagnosis from AML patients. Samples were incubated for 48 hours in 96 well plates, each well containing different drugs or drug combinations at 8 different concentrations, enabling calculation of dose-response (DR) curves for each single drug (CYT, IDA, DNR, MIT) and combination used in treatments (CYT-IDA, CYT-DNR, CYT-MIT). *ex vivo* drug sensitivity analysis was made using the PharmaFlow platform maintaining the BM microenvironment. Drug response was evaluated as depletion of AML blast cells in each well after incubation. Annexin V-FITC was used to quantify the ability of the drugs to induce apoptosis, and pharmacological responses were calculated using pharmacokinetic population models.

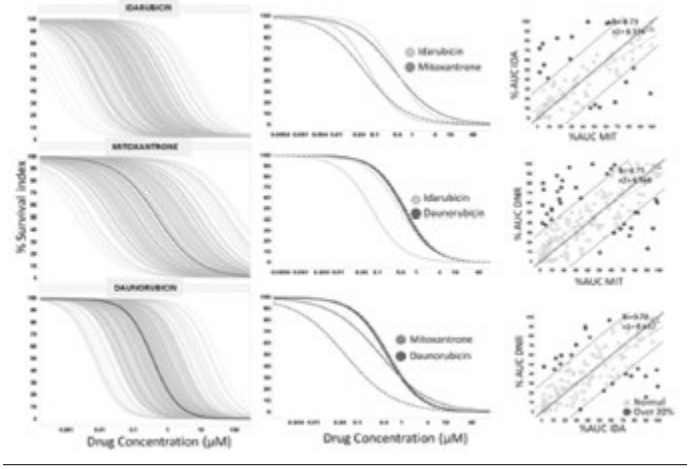

Figure 1.

Results: DR graphs were generated for each anthracycline (IDA, DNR and MIT) using PD models. Left panel of figure 1 shows the individual (grey lines) and average DR for IDA (yellow), MIT (blue) and DNR (red) from 289, 274 and 333 AML patients, respectively. As we expected, the average dose responses of the four anthracyclines were similar, with a slight increase in survival index with IDA. However, the interpatient variability of either drug is quite large, which could explain the differences in anthracycline sensitivity reported in some patients. As an example, middle panel figure 1 shows a patient sample that is resistant to IDA and DNR but sensitive to MIT. To identify those cases of selective sensitivity to anthracyclines, we compared the potency, in terms of AUC, between IDA *vs* MIT, DNR *vs* MIT and DNR *vs* IDA (right panel figure 1). Most dots tend to line up, but red dots represent patient samples with a difference in potency between these drugs greater than 30%. Red dots from 3 pairwise comparisons identify 28.3% of patient samples with this different potency between single anthracyclines. Similar DR graphs were generated for CYT-IDA, CYT-DNR and CYT-MIT combinations. The pairwise comparison of these combination treatments obtained different sensitivity in 8.2% of patients. Overall differences in sensitivity combining both the monotherapies and the CYT combinations were 30.6%.
Summary/Conclusion: These results show that this PM test seems able to identify a subset of AML patients whose *ex vivo* pharmacological response to anthracyclines is significantly different. A fraction of these patients may benefit if treatment selection among these alternatives were to be aided by this PM *ex vivo* test. To identify which fraction would benefit we would need a trial specifically designed.

PB1721

IMPACT OF DIFFERENT BY INTENSITY CONSOLIDATION REGIMENS ON MINIMAL RESIDUAL DISEASE REDUCTION AND RELAPSE INCIDENCE IN ADULTS WITH ACUTE MYELOID LEUKEMIA

T. Lobanova*, E. Parovichnikova, I. Galtseva, Y. Davydova, N. Kapranov, V. Troitskaya, A. Sokolov, I. Lukianova, V. Savchenko

Hematological Oncology and BMT, National Research Center for Hematology, Moscow, Russian Federation

Background: As low minimal residual disease (MRD) value at any time point, assessed by multicolor flow cytometry (MFC) correlates with the better outcome in AML patients (pts), it seems very important to evaluate the impact of treatment intensification on MRD level reduction.
Aims: The aim of the study was to compare the MRD clearance after standard and after intensive consolidation cycles in AML patients and to reveal risk factors of the relapse.
Methods: From March 2016 to February 2018, 60 pts with *de novo* AML (median age 37, 18-60 yy) were treated in the National Research Center for Hematology, Moscow, with 7+3 (Ara-c 200 mg/m^2 c.i, 1-7 days, Daunorubicin 60 mg/m^2 1-3 days) as the 1st induction cycle. 39 pts in complete remission (CR) after induction completion were included in the MRD study, comparing different consolidation intensity approaches: (A) 26 pts received 3 «7+3» consolidation cycles with anthracyclines alternation (Daunorubicin 60 mg/m^2 in 1st cycle, Idarubicin 12 mg/m^2 in 2nd cycle and Mitoxantrone 10 mg/m^2 in 3rd 1-3 days with Ara-c 100 mg/m^2 bid 1-7 days in each cycle); (B) 13 pts received consolidation with 2 FLARIDA courses (Fludarabine 30 mg/m^2 1-4 days, Ara-c 1000 mg/m^2 1-4 days, Idarubicin 8 mg/m^2 1,3 days). The (A) and (B) cohorts were similar by the age and ELN risk groups. Allogeneic HSCT was performed in 19 pts. MRD was measured in the bone marrow after induction and consolidation by 6 color-MFC on FACS Canto II with a standard antibody panel and 4 tubes, including anti-CD34, CD33, CD117, CD45, CD13, CD11b, CD66b, HLA-DR, CD2, CD4, CD7, CD56, CD38, CD14, CD15, CD16, CD19, CD65, CD99 antibodies. Any detectable MRD value was estimated as MRD positivity; sensitivity level was 0.01%.
Results: CR after 1st induction 7+3 in the whole cohort was achieved in 41 pts (68%) with MRD-negativity in 27 (65,8%) of them. 26 CR pts after 7+3 consolidation in (A) group have demonstrated much less duration of critical neutropenia (<0,5*10^9/l) in comparison with 13 CR pts after FLAR-IDA in (B): 16(1-47) days and 18(0-35), respectively (p=0,029); median intervals between consolidation courses constituted 32 (30-67) days in (A) *vs* 38 (29-57) in (B) (p=0,005). The frequency of severe septic complications did not differ in both cohorts: 23.1% (A) *vs* 46.1%, (B) (p=0,16). MRD-positivity after the 2nd cycle was 3/26 (11,5%) in (A) and 5/13 (38,4%) in

(B) cohorts (p=0,08). The same results were obtained after the whole consolidation program-MRD-positivity in 4/21(19%) in (A) and in 2/11 (18%) in the (B) groups (p=0,95). The pts who were MRD-positive after 1st induction had significantly higher relapse risk than MRD-negative: 6/15 (40%) *vs* 1/27 (3,7%) (p=0,005). Relapse frequency in pts who were MRD-negative after the 2nd course was 26% (6/23) in (A) cohort and 12,5% (1/8) in the (B). The incidence of relapse during 12 months after CR achievement constituted 30,7% in (A) and 23% in (B) cohorts with no significant difference (pic.1).

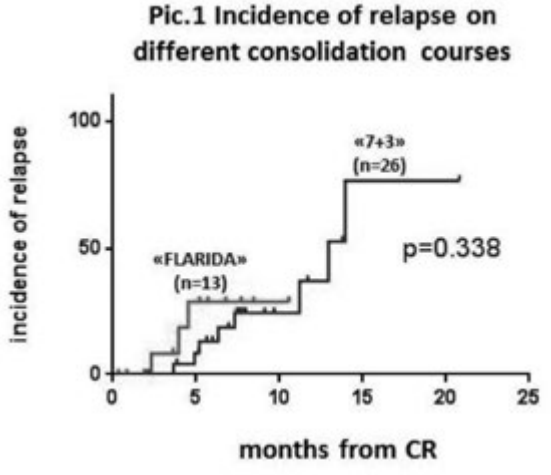

Figure 1.

Summary/Conclusion: Though the studied groups are small, we can assume that intensification of consolidation treatment was not translated into better MRD clearance. Moreover, escalation of the chemotherapy induced more profound and prolonged neutropenia with the higher risk of severe infections and more durable intervals between consolidation cycles. The incidence of relapse was comparable in the different by intensity consolidation groups. It's worth to note that the achievement of MRD negativity after the first induction cycle is associated with better outcome.

PB1722

AN EFFECTIVE TOOL FOR COMPREHENSIVE GERIATRIC ASSESSMENT IN ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA

C.-L. Zhang*, H. Liu, R. Feng, J.-T. Li, Y. Tian, T. Wang

Department of Hematology, Beijing Hospital, Beijing, China

Background: Acute myeloid leukemia (AML) is one of the common types of hematological malignancies in elderly people. Thus, how to select patients who are suitable to receive intensive induction chemotherapy is critical to improve the clinical outcomes of elderly patients with AML. Over the last few decades, geriatricians have developed comprehensive geriatric assessment (CGA) methods for elderly patients, which are useful for the evaluation of cancer patients. however, the tools used for CGA varied and not uniform in AML.
Aims: We aimed to validate the instrumental activities of daily living (IADL) scales, age, comorbidities, and albumin (IACA) index in elderly patients with acute myeloid leukemia (AML) and identify whether this index can serve as a guide for optimal personalized therapy for elderly patients with AML.
Methods: Patients aged ≥60 years, who had been diagnosed with AML in the Department of Hematology, Beijing Hospital, were screened for eligibility (n=61).
Results: A total of 21, 34, and 6 patients were categorized as IACA low-risk, intermediate-risk, and high-risk groups, respectively. Thirty-nine patients received induction chemotherapy (IC, n=35) or decitabine (n=4) after diagnosis, 19 (48.7%) achieved complete remission (CR), and the rate of CR was significantly higher in the IACA low-risk group than that of intermediate-risk group (68.4% *vs* 30.0%, P=0.016).The rates of grade ≥3 toxicities and treatment-related mortality were comparable between low- and intermediate-risk groups. The rate of relapse/progression-related mortality was 23.8%, 58.8%, and 100.0% in the IACA low-, intermediate-, and high-risk groups, respectively (P<0.001). The 2-year probability of overall survival (OS) was 47.7% and 20.2% in the IACA low- and intermediate-risk groups, respectively, which were both significantly higher than that of the high-risk group (0.0%). In the IACA low-risk groups, the 2-year probability of OS in patients receiving IC was significantly higher than in those receiving best supportive care (50.8% *vs* 0.0%, P<0.001) .
Summary/Conclusion: We observed that the IACA index could predict the clinical outcomes of elderly patients with AML, and the IACA low-risk patients may benefit more from IC.

PB1723

ALTERATIONS IN SERUM BILIRUBIN DURING TREATMENT WITH ENASIDENIB IN PATIENTS WITH OR WITHOUT UGT1A1 MUTATIONS

A.T. Fathi[1,2,*], C.D. DiNardo[3], I. Kline[4], N. Tu[4], E.C. Attar[5], E.M. Stein[6,7], S. de Botton[8]

[1]Massachusetts General Hospital Cancer Center, [2]Harvard Medical School, Boston, [3]The University of Texas MD Anderson Cancer Center, Houston, [4]Celgene Corporation, Summit, [5]Agios Pharmaceuticals, Inc., Cambridge, [6]Memorial Sloan Kettering Cancer Center, [7]Weill Cornell Medical College, New York, United States, [8]Gustave Roussy, Villejuif, France

Background: Enasidenib is an oral, potent inhibitor of mutant IDH2 (mIDH2) proteins. In a phase 1/2 study (NCT01915498) in patients with m*IDH2* myeloid malignancies, 38% of patients developed bilirubin elevations, likely due to off-target inhibition of the UGT1A1 enzyme, which metabolizes bilirubin in humans. Homozygous *UGT1A1* mutations (*UGT1A1*$^{mut/mut}$) are associated with inherited Gilbert Syndrome. A protocol amendment was added to include *UGT1A1* gene testing at patient screening.
Aims: To evaluate bilirubin changes associated with *UGT1A1* mutational status of patients with m*IDH2* hematologic malignancies in the phase 1/2 study of enasidenib monotherapy.
Methods: Enasidenib doses ranged from 50 to 650 mg/day. Total blood bilirubin (TBili) was assessed in all patients at baseline and at each site visit. Normal TBili ranges varied among reference labs (~3-25 µmol/L).
Results: As of Sept 2017, *UGT1A1* data were available for 65 patients: 16 patients had homozygous m*UGT1A1* (*UGT1A1*$^{m/m}$), 27 had heterozygous m*UGT1A1* (*UGT1A1*$^{mut/wt}$), and 22 had wild type *UGT1A1* (*UGT1A1*^{wt}). 60 patients received enasidenib 100 mg/d and 5 patients (*UGT1A1*$^{mut/mut}$ n=2; *UGT1A1*$^{mut/wt}$ n=3) received >100 mg/d enasidenib. Mean TBili at baseline was similar among the 3 genotypes (**Table**). Patients with *UGT1A1*$^{mut/mut}$ had more rapid TBili increases during early treatment than the 2 other genotypes, followed by stabilization of TBili levels; mean increases from baseline during treatment in patients with *UGT1A1*$^{mut/mut}$ indicated mild hyperbilirubinemia (~1.5 x ULN). Mean TBili levels during treatment in patients with *UGT1A1*$^{mut/wt}$ or *UGT1A1*^{wt} were within normal range (**Table**). Indirect bilirubin increases followed similar patterns to those of TBili. AST or ALT increases to ≥3 x ULN during Tx were not more frequent in *UGT1A1*$^{mut/mut}$ patients (6%) than in *UGT1A1*$^{mut/wt}$ (15%) or *UGT1A1*^{wt} (14%) patients. Incidence of treatment-emergent adverse events of hyperbilirubinemia were similar among genotypes although more patients with *UGT1A1*$^{mut/mut}$ (13%) or *UGT1A1*$^{mut/wt}$ (11%) had grade 3 bilirubin events than patients with *UGT1A1*^{wt} (0%). Dose interruptions or reductions due to increased TBili were infrequent in patients with m*UGT1A1* and none were reported for *UGT1A1*^{wt} patients.

Table 1.

Mean ±SD Total Bilirubin

	UGT1A1$^{mut/mut}$ N=16	*UGT1A1*$^{mut/wt}$ N=27	*UGT1A1*^{wt} N=22
	µmol/L		
BL	10.9 ± 7.1	9.5 ± 4.2	9.7 ± 4.0
C1D15	27.9 ± 21.0	18.4 ± 9.0	16.1 ± 6.7
C2D1	31.8 ± 26.7	18.2 ± 6.7	18.7 ± 8.4
C2D15	28.4 ± 14.0	22.9 ± 10.4	20.0 ± 8.8
C3D1	28.8 ± 14.1	21.6 ± 13.3	20.8 ± 8.0
C4D1	29.3 ± 14.3	21.9 ± 16.2	22.3 ± 9.1

C, cycle; D, day

Summary/Conclusion: These data suggest initial enasidenib dose restrictions are not necessary for patients with *UGT1A1* mutations; however, if dose reductions for hyperbilirubinemia are made, they should be informed by the enasidenib prescribing information.

PB1724

EFFECT OF A HIGH-FAT AND HIGH-CALORIE MEAL ON THE PHARMACOKINETICS (PK) OF QUIZARTINIB (Q) AND ITS ACTIVE METABOLITE

J. Li[1,*], M. Holmes[1], M. Kankam[2], D. Trone[3], J. Mendell[4], G. Gammon[3]

[1]Daiichi Sankyo, Inc., San Diego, [2]Vince & Associates, Overland Park, [3]Formerly Daiichi Sanyko, Inc., San Diego, [4]Daiichi Sankyo, Inc., Basking Ridge, United States

Background: Quizartinib (Q) is an oral, highly potent and selective, next-generation FMS-like tyrosine kinase 3 (FLT3) inhibitor. Q has demonstrated promising activity in early clinical studies for treatment of AML and is currently in phase 3 studies for treatment of *FLT3*-internal tandem duplication (ITD) mutated AML.
Aims: In preclinical studies in rats, food increased oral absorption of Q. Therefore, this study aimed to characterize the effect of a high-fat, high-calorie meal on plasma PK parameters of Q in healthy subjects after a single administration of Q. An additional aim was to evaluate tolerability and safety of Q when administered with or without food.
Methods: Healthy subjects, ages 18-55, were randomized in parallel groups to receive a single 30-mg tablet (formulation used in phase 3 trials) of Q (administered as Q dihydrochloride and equivalent to 26.5 mg free-base) under fasted conditions or after a high-fat, high-calorie meal (fed condition). Plasma levels of Q and its active metabolite, AC886, were measured immediately before Q dosing through 504h post dose using a validated method. PK parameters of Q, AC886, and Q+AC886 were determined using non-compartmental modeling. Ratios (fed/fasted) of geometric least squares means (Geo LSM) and 2-sided 90% confidence intervals (CI) of C_{max}, AUC_{last}, and AUC_{inf} of Q were calculated to assess effect of food on PK. A 90% CI entirely within an 80% >125% limit indicated no food effect. Safety and tolerability were assessed.
Results: 66 subjects were enrolled; 64 received study treatment, 30 under fed conditions and 34 under fasted conditions. Overall, 75% of treated subjects were male and the median age of subjects was 34 years. Mean PK profiles of Q administered under fasted and fed conditions were similar. Administration of Q in the fed condition led to ~8% decrease in C_{max}, and increases of ~5% and 8% to AUC_{last} and AUC_{inf}, respectively, *vs* the fasted condition. The 90%CI for the ratio of the fed *versus* fasted condition fell within the 80%>125% limits for C_{max} and AUC_{last}, and the upper bound of the 90%CI for AUC_{inf} was slightly outside the 125% limit (~128%). Similar trends were also observed for C_{max}, AUC_{last}, and AUC_{inf} for AC886 and Q+AC886. Presence of food delayed T_{max} of Q by 2h (T_{max} was 4h in fasted *vs* 6h in fed subjects). $T_{1/2}$ of Q and AC886 was comparable in fasted and fed conditions. All TEAEs reported were mild or moderate; no serious AEs or discontinuations due to AE occurred. Overall, 6 subjects (9.4%) had a TEAE considered related to Q: 2 subjects in the fed condition and 4 subjects in the fasted condition. No significant ECG abnormalities were observed.

Table 1. Statistical Analysis of Q PK Parameters.

PK Parameter	Fed State Geo LSM (N)	Fasted State Geo LSM (N)	Ratio of Geo LSM (fed/fasted), %	90% CI for Ratio of Geo LSM
C_{max}, ng/mL	90.94 (29)	99.31 (34)	91.58	82.15, 102.08
AUC_{last}, ng*h/mL	8788.07 (29)	8338.27 (34)	105.39	90.79, 122.35
AUC_{inf}, ng*h/mL	9459.56 (27)	8727.51 (30)	108.39	91.54, 128.34

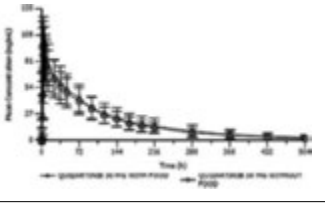

Figure 1.

Summary/Conclusion: Administration of food resulted in slight increase in Q exposure, but is not clinically relevant. TEAEs were similar following Q administration in the fed and fasted conditions. Therefore, Q can be administered with or without food.

PB1725

A DRUG-DRUG INTERACTION STUDY TO ASSESS THE EFFECT OF ACID REDUCING AGENT, LANSOPRAZOLE, ON QUIZARTINIB PHARMACOKINETICS

J. Li[1,*], D. Trone[2], J. Mendell[3], P. O'Donnell[1], N. Cook[1]

[1]Daiichi Sankyo, Inc., [2]Formerly Daiichi Sankyo, Inc., San Diego, [3]Daiichi Sankyo, Inc., Basking Ridge, United States

Background: Quizartinib is a highly potent, selective FLT3 inhibitor currently being investigated in phase3 studies in patients with AML with *FLT3* internal tandem duplication mutations. Acid reducing agents (ARA) such as proton pump inhibitors are frequently used during AML treatment.
Aims: To evaluate the effect of gastric pH on bioavailability of quizartinib, using *in vitro* data describing pH-dependent solubility profile of quizartinib dihydrochloride as a drug substance, and data from a phase 1 study in healthy volunteers to assess the effect of ARA (the proton pump inhibitor lansoprazole) coadministered with quizartinib as a tablet formulation, on pharmacokinetics (PK) of quizartinib.
Methods: pH-dependent solubility of quizartinib dihydrochloride as a drug substance was evaluated in aqueous buffers at pH 1.1-8.0 at 37°C. Healthy adult subjects were randomized in an open-label, parallel-group study to receive quizartinib alone (single dose of 30 mg quizartinib dihydrochloride tablet formulation [equivalent to 26.5 mg free base]) or lansoprazole + quizartinib (lansoprazole 2 × 30-mg oral delayed-release capsule once daily from Days 1 to 5; single dose of 30 mg quizartinib on Day 5). Plasma concentrations of quizartinib and its active metabolite, AC886, were measured to 504 hours post dose. PK parameters included maximum observed plasma concentration (C_{max}) and area under the concentration-time curve to infinity (AUC_{inf}). Effect of lansoprazole on quizartinib PK was assessed by analysis of variance. Safety and tolerability were also assessed.
Results: The solubility of quizartinib dihydrochloride as a drug substance decreased sharply with pH ≥2 (Figure). In the phase 1 study (enrolled N=64), 63 subjects received quizartinib and 59 completed the study. Coadministration of lansoprazole resulted in a lower quizartinib C_{max} (~14%) and AUC_{inf} (~5%; Table). The 90% CI for the ratio of AUC_{inf} fell within the 80% to 125% limits. The lower bound of the 90% CI for AUC_{last} and C_{max} were slightly below the limit at 79.6% and 78.4%, respectively. However, this decrease is not considered a clinically significant effect. A similar trend was observed with AC886. All treatment-emergent adverse events were mild (n=19) or moderate (n=1; headache).

Table 1. Statistical ANOVA Comparisons of Quizartinib Pharmacokinetic Parameters.

PK Parameter	Q+L		Q Alone		Ratio of Geo LSM ((Q+L)/Q), %	90% CI for Ratio of Geo LSM
	n	Geo LSM	n	Geo LSM		
C_{max}, ng/mL	32	90.3	30	104.8	86.11	78.36-94.64
AUC_{last}, ng*h/mL	32	7825.6	30	8328.9	93.96	79.63-110.86
AUC_{inf}, ng*h/mL	31	8257.4	30	8664.7	95.30	80.16-113.30

ANOVA, analysis of variance; CI, confidence interval; Geo LSM, geometric least squares mean; L, lansoprazole; Q, quizartinib.

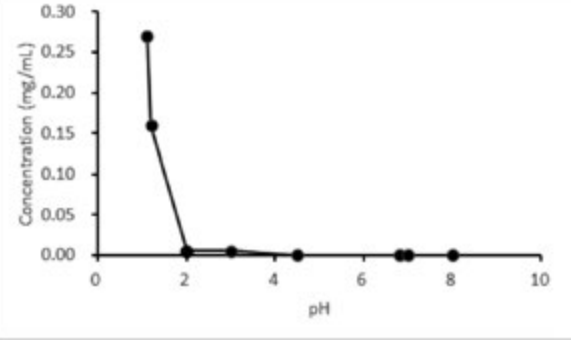

Figure 1.

Summary/Conclusion: Although quizartinib dihydrochloride demonstrated pH-dependent solubility *in vitro* as a drug substance, the proton pump inhibitor lansoprazole had no clinically significant effect on quizartinib PK. Quizartinib as a formulated tablet can be coadministered with and without acid reducing agents.

PB1726

PHARMACOKINETICS OF HU5F9-G4 A FIRST IN CLASS ANTI-CD47 ANTIBODY IN PATIENTS WITH ACUTE MYELOID LEUKEMIA

B. Agoram[1,*], B. Wang[2], P. Vyas[3], M. Dennis[4], R. Kelly[5], S. Knapper[6], R. Salim[7], H. Johnson[8], C. Roberts[9], J. Liu[10], R. Secreto[11], C. Takimoto[12], M. Chao[12]

[1]Clinical Pharmacology, FortySeven Inc, Menlo Park, [2]Clinical Pharmacology, LucidCPS, Pleasanton, United States, [3]Clinical, University of Oxford and Oxford University Hospitals, Oxford, [4]Clinical, Christie NHS Foundation Trust, Manchester, [5]Clinical, Leeds Teaching Hospitals NHS Trust,, Leeds, [6]Clinical, Cardiff University School of Medicine, Cardiff, [7]Clinical, Royal Liverpool University Hospital, Liverpool, [8]Clinical, [9]Centre for Statistics in Medicine, University of Oxford, Oxford, United Kingdom, [10]Research and Development, FortySevenInc, [11]Clinical Operations, [12]Clinical development, FortySeven Inc, Menlo Park, United States

Background: Hu5F9-G4 (5F9) is a humanized monoclonal antibody targeting CD47, a protective "don't eat me" signal on cancer cells. Blocking CD47 stimulates tumor cell phagocytosis and activates an anti-tumor T-cell response. Pre-clinically, 5F9 eliminates leukemic disease and induces durable remissions in patient-derived xenograft mouse models.
Aims: The objectives of this analysis were to characterize the pharmacokinetics (PK) and anti-drug antibody (ADA) incidence of 5F9 after single and multiple doses in patients with acute myeloid leukemia (AML).
Methods: Data from the Phase 1 CAMELLIA study (MRC grant: MR/L008963/1) were used for this analysis. Multiple intravenous (IV) doses of Hu5F9 in the range 0.1-30 mg/kg were given at twice weekly frequency. PK samples were drawn in all patients after single and multiple doses. A total of 13 AML patients provided PK and ADA data. PK data were analyzed by a noncompartmental approach using the PKNCA package in R language. Population modelling using NONMEM software was performed by combining PK data in AML patients with data from patients with solid tumours and lymphomas. Model-estimated individual PK parameters (linear and nonlinear clearance, and volume of distribution) were used to compare PK parameters in AML *vs* solid tumour patients. Simulations using the model were used to identify optimal Phase 2 dose in AML patients. Presence of ADA was analyzed using a 3-tiered approach consisting of screening, confirmatory, and titre determination.
Results: Increases in maximum serum concentration (C_{max}) of 5F9 were greater than dose-proportional in the dose range 0.1-10 mg/kg indicating nonlinearity in PK. At doses ≥10 mg/kg, increases in C_{max} were linear. The PK parameters were consistent with the presence of a CD47 antigen sink, which was saturated at doses ≥10 mg/kg. Population PK modelling indicated that PK parameters in AML patients were similar to those estimated in solid tumour patients. Simulations with the model predicted that a maintenance dosing regimen of 30 mg/kg every week after week 2 would result in serum concentrations ≥200μg/mL, a level where near-maximal CD47 receptor occupancy on blood and bone marrow cells was observed in this study.
ADA was confirmed in 1 subject (7.7%) in this study but had no observable impact on the PK parameters.
Summary/Conclusion: 5F9 exhibits nonlinear PK in AML patients, typical of a receptor-targeted antibody. The PK in AML patients is similar to that in patients with solid tumours. The immunogenic potential of 5F9 in AML patients is low. Overall, the PK profile of 5F9 is suitable for once weekly dosing in AML patients. Ongoing studies in AML have implemented this dosing regimen (NCT03248479).

PB1727

EFFICACY AND SAFETY OF C-CAG REGIMEN (CLADRIBINE,G-CSF, LOW-DOSE CYTARABINE AND ACLARUBICIN) IN PATIENTS WITH REFRACTORY/RELAPSED ACUTE MYELOID LEUKEMIA: A PHASE 2, SINGLE CENTER, SINGLE ARM STUDY

H. Wang, Y. lu*, Y. wang

Hematological Oncology, Sun Yat-Sen University Cancer Center, Guangzhou, China

Background: Although the considerable advances have been made in the treatment of acute myeloid leukemia (AML) in recent decades, only one third of patients (except for acute promyelocytic leukemia) can be cured, and most suffer relapse or primary refractory (R/R). However, there is no standard regimen for R/R AML patients after conventional chemotherapy.A regimen consisting of granulocyte colony-stimulating factor (G-CSF) priming the combination of low-dose cytarabine (Ara-C) and aclarubicin, termed the CAG regimen,was first reported by a Japanese group in 1995. It has been proved that cladribine is a attractive drug in AML because of their significant synergy with other chemotherapeutic agents and favorable toxicity profile. Efforts were made to improve the efficacy of the CAG regimen among institutions, including combining it with other chemotherapy drugs.
Aims: Therefore, the purpose of this study is to prospectively evaluate efficacy and safety of C-CAG regimen (cladribine in combination with granulocyte colony-stimulating factor, low-dose cytarabine and aclarubicin) in patients with R/R AML (**This study was registered at www.chictr.org, the Clinical Trial Registration Number was ChiCTR-OPC-16010166**).

Table 1.

Patients Characteristics.

Characteristics	n	(%)
Age [median (range), years]	34	
< 60 years	10	90.9
≥60 years	1	9.1
Sex		
Male	5	45.5
Female	6	54.5
FAB subtypes		
M2	5	45.5
M4	1	9.1
M5	5	45.5
Blood cell count before re-induction		
WBC (×10^9/L, mean±SD)	19.6±4.75	
PLT (×10^9/L, mean±SD)	72.8±7.54	
HB (×g/L, mean±SD)	97.0±2.61	
Cytogenetic risk group,		
Low risk	3	27.2
Intermediate risk	4	36.4
High risk	4	36.4
Disease status		
Relapse	9	81.8
Refractory	2	18.2
Duration of first complete remission, months (range)	10	

Methods: Enrolment began in August 2016 for a Phase II single-center clinical trial. The patients in this arm will receive C-CAG regimen for salvage treatment,detailed as following:Cladribine 5mg/ ,d1-5 G-CSF 300ug,d0-9; aclarubicin 10mg,d3-6;cytarabine 10mg/ q12h, SC, d3-9;4 weeks a cycle.The patients are permitted to quit the study if complete remission(CR) is not achieved after 2 course of chemotherapy. If conditions were right,the patients achieving CR were recommended to receive allogeneic hematopoietic stem cell transplantation(HSCT). Otherwise, the patients were given for a total of six cycles unless there was disease progression or unacceptable side effects, or withdrawal of patient consent.
Results: Until December 2, 2017, we have completed the enrolment of 11 patients with R/R AML. The main clinical characteristics of the 11 patients are presented in Table 1. The median age was 34 years and ranged from 18 to 72 years. The majority of patients presented with FAB subtype of M2 or M5. All patients(n=11)have begun treatment and are evaluable for response. Of the 11 patients, complete remission rates is 72.7% to C-CAG regimen. No patients received allogeneic transplantation due to scarcity of bone marrow donors or inability of the patients to afford the expensive medical treatment.At a median follow-up of 8 months (3–18), the 1-year PFS and OS rates for all 11 patients were 43.6 and 62.3%,respectively .The most common adverse effect was myelosuppression. The incidence of grade 3 or 4 hematological toxicity was 90.9%.The respective median duration of neutropenia (neutrophils<0.5×10^9/L) was 7 days. The median time of platelet recovery over 50 × 10^9/L was 12 days.All patients presented an incidence of 4.1% for Grade 3 or 4 infectious toxicity. No treatment-related deaths occurred. Non-hematological side effects were mild. Grade 3 or 4 gastrointestinal side effects were rarely observed, owing to the prophylactic antiemetic drug administration.
Summary/Conclusion: Preliminary data indicate that the C-CAG regimen chemotherapy is significantly effective against R/R AML with a high remission rate and a low hematological toxicity, thus serves as an alternative treatment for R/R AML.

PB1728

HEALTH RELATED QUALITY OF LIFE (HRQOL) IN ACUTE MYELOID LEUKEMIA (AML) PATIENTS NOT ELIGIBLE FOR INTENSIVE CHEMOTHERAPY (NIC AML): RESULTS OF A SYSTEMATIC LITERATURE REVIEW

A. Forsythe[1,*], C.S. Kwon[1], T. Bell[2], T.A. Smith[3], B. Arondekar[2], A.P.J. Rabe[1]

[1]Purple Squirrel Economics, [2]Pfizer Inc, New York, United States, [3]Pfizer Ltd, Walton Oaks, United Kingdom

Background: AML is diagnosed at a median age of 67; once over 60 years of age, the 5-years survival rates for patients with AML fall substantially because they are often not eligible for intensive chemotherapy (NIC). Less intensive chemotherapeutic agents and best supportive care are potential treatment options in this population. There is scant published literature on

the impact of disease and treatment on the health-related quality of life (HRQoL) in NIC AML patients.
Aims: We aimed to determine the reported quality of life among NIC AML patients.
Methods: We conducted a systematic literature review (SLR) of evidence on HRQoL reported in patients with NIC AML. MEDLINE, Cochrane database, and conference abstracts (EHA, ASCO, ESMO, and ASH) were searched using matches on pre-specified population, interventions, comparators, outcomes and study designs (PICOS approach) from January 2000 through November 2017 for relevant studies that reported HRQoL and patient preference utilities in NIC AML. Based on the WHO AML criteria, studies on patients with RAEB-t myelodysplastic syndrome (MDS) (≥20% bone marrow blast) were also included. Randomized clinical trials (RCTs), prospective observational studies and patient surveys were included. Systematic reviews and meta-analyses were used for bibliographic search. Two researchers independently selected trials, assessed trial quality, and extracted and analysed data.
Results: A total of 13 records from 12 original studies were identified. These included 5 records from 4 original RCTs, 3 prospective studies, 4 patient survey studies, and 1 cost-effectiveness analysis reporting utility values. Ten studies utilized the EORTC QLQ-C30 questionnaire, 5 reported EQ-5D values. Other scales used included QOL-E, QOL Cancer Survivor, FACT-Leukemia, FACT-Fatigue, Global Fatigue Scale, FACIT Fatigue, Activities of Daily Living index and Hospital Anxiety and Depression Scale. Four QLQ-C30 domains were considered most relevant: fatigue, physical function (PF), Global Health Status (GHS) and dyspnea. A 10-point minimally important difference (MID) threshold on a 100-point scale was assumed by a majority of studies to represent meaningful change. At baseline, NIC AML patients had poor HRQoL scores especially in fatigue (33) and GHS (50) on a 0-100 scale, with higher scores indicating better health. Low baseline HRQoL scores, especially PF and fatigue (<50) were shown to be significant independent predictors of poor survival. Clinical responders demonstrated meaningful improvements in QLQ-C30 physical, role, cognitive and social functioning, GHS, fatigue and EQ-5D scores from baseline after being treated with chemotherapy. Clinically meaningful and significant improvements in fatigue and PF were observed with non-intensive chemotherapeutic agents across several studies.
Summary/Conclusion: Although HRQoL is highly subjective, it plays a crucial role in the treatment of AML patients. Fatigue and physical function at baseline have been identified as independent prognostic factors for overall survival with several studies showing improvement in both domains with treatment. Randomized controlled studies should incorporate evaluation of treatment impact on patient's physical function and fatigue as important measures of effectiveness.

PB1729

IMPORTANCE OF CLINICAL RISK IN CYTOGENETIC-MOLECULAR FAVOURABLE RISK AML WITH NPM MUTATED, FLT3-ITD UNMUTATED AND NORMAL KARYOTYPE

M.V. Dubbini*, A. Candoni, M.E. Zannier, C. Filì, D. Lazzarotto, N. Rabassi, S. Frisoli, R. De Marchi, D. Schiavo, R. Stella, E. Simeone, R. Fanin

Division of Hematology and Stem Cell Trasplantation, Azienda sanitaria Universitaria Integrata di Udine, Udine, Italy

Background: Acute Myeloid Leukemia (AML) with NPM mutated (NPM+), FLT3-ITD unmutated (FLT3-) and Normal Karyotype (NK) are included in the favourable cytogenetic-molecular risk class according to the 2010 and 2017 classifications. Frequently, in clinical practice, we focus only on this cytogenetic-molecular risk to define the AML prognosis regardless of clinical risk profile (particularly secondary AML and high blast cells count-BC in peripheral blood-PB, at onset).
Aims: We analyse clinical characteristics, response to chemotherapy (Complete Remission-CR), relapse rate (RR) and outcome of 29 AML NPM+/FLT3-/KN that were homogeneusly treated at our Center in the least 10 years.
Methods: There were 15 female and 14 male with a median age of 53,5 yrs (range 20-68) and 21% of cases had more than 65 yrs. Four (14%) AML were secondary to a previous Myelodysplastic Syndrome and 41% (12/29) had more than 30.000/mmc BC in PB at onset. Overall 52% of case are at High Clinical Risk (HCR) at diagnosis. All patients (pts) were treated with FLAI scheme (Fludarabine, Cytarabin-Ara-C, Idarubicin) as induction, followed by Intermediate dose Ara-C+Idarubicin and High Dose Ara-C, as consolidation therapy.

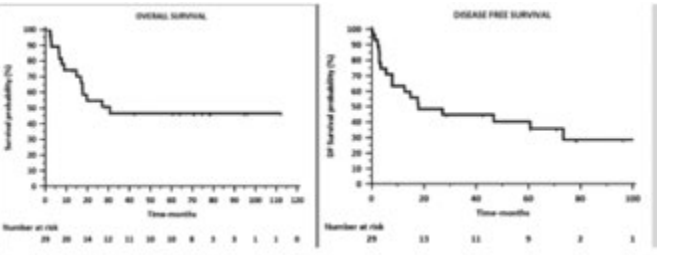

Figure 1.

Results: The CR after FLAI was 90% (26/29 cases) and only 7% (2/29) of pts were resistant. DDI was 0%. After a median follow up of 20 months (2-112), 52% of pts (15/29) are alive and 48% (14/29) died. The RR was 41% (12/29) and 8/12 relapsed pts (67%) had CHR at diagnosis. Allo-SCT rate was 41% (12/29) and Allo SCT was performed mainly in CHR and after relapse. The probability of OS at 12, 24 and 36 mths, was 74%, 55% and 47%, respectively (FIGURE 1). The probability of DFS at 12, 24 and 36 mths, was 60%, 48% and 45%, respectively (FIGURE 1). The OS and DFS did not differ between CHR and other pts but we underline that a significant higher proportion of CHR pts received Allo-SCT (10/15 CHR cases *vs* 2/14 other cases, P<0,05) mainly after their relapse.
Summary/Conclusion: In our experience the AML with NPM+/FLT3-/KN have a RR not negligible (41%) with a probability of DFS at 24 mths of 48%. The relapse occured mainly (67%) in pts with CHR (high PB-BC and secondary AML). For this CHR population early and close monitoring of minimal residual disease (quantitative NPM-today available) should be performed in all cases in order to avoid cytologic relapse and to decide if it is worth consolidating their cytologic CR with Allo SCT.

PB1730

IMPACT OF INFECTION PRIOR TO THE INITIATION OF INDUCTION CHEMOTHERAPY ON INDUCTION OUTCOMES IN PATIENTS WITH NEWLY DIAGNOSED ACUTE LEUKEMIA IN A TERTIARY CENTRE HOSPITAL IN INDIA

R.R.[1,*], S.T.[1], M.M.[1], S.R.[1], J.V.[2]

[1]Dept of Hematology, AIIMS Delhi India, New delhi, [2]Radiology, AIIMS, Delhi, India

Background: There is paucity of published data regarding the treatment strategy of patients infected at baseline prior to initiation of induction chemotherapy.
Aims: To determine the impact of infection at baseline(prior to the initiation of chemotherapy) in acute leukemia patients undergoing induction chemotherapy with respect to mortality and CR rates.
Methods: Ambispectively (from 1-7-2015 to 31-12-2017) we included newly diagnosed patients with acute leukemia undergoing induction chemotherapy.
Results: A total of 268 admitted in-patients of acute leukemia were screened in the Dept of Hematology at All india Institute of Medical sciences(AIIMS), New Delhi, India. Out of these 124 admitted patients were found to have infections at baseline prior to initiation of induction chemotherapy. A large proportion of admitted infected acute leukemia patients died before the initiation of induction chemotherapy (54.83%).The median duration of illness prior to admission in the group of infected patients who later proceeded on to receive induction chemotherapy was longer in comparison to patients without infection and this difference was statistically significant (12 weeks *versus* 6 weeks, p<0.00001). Ninety-six percentage of the patients with baseline infection prior to initiation of induction chemotherapy were treated with IV antibiotics and antifungals each. The mean duration of therapeutic antibiotic therapy and antifungal therapy prior to induction chemotherapy was 16.08 days and 13.6 days respectively. Prior to the initiation of induction chemotherapy it was determined that clinically 78% of patients had improvement in the status of their infection, twelve percentage had complete resolution of the documented baseline infection.In the patients with baseline infection, after initiation of induction chemotherapy, the majority (82%) developed either new infections and/or worsening of pre-existing infections in comparison to the group without infection at baseline (53.73%), and this difference was statistically significant (p=0.0005). Lesser proportion of the uninfected patients at baseline developed febrile neutropenia (53.73%) in comparison to the group with baseline infections (80%) upon induction chemotherapy initiation, and this difference was statistically significant(p=0.0012). After the initiation of chemotherapy the occurrence of septic shock in the group of patients with infection at baseline (42%) was more frequent than in the group without infection at baseline

(22.388%) and this difference was statistically significant (p=0.0084). The difference in the induction mortality rates in both groups was not significant statistically (32% in baseline infected group *versus* 23.13% in the uninfected group, p=0.1968), even on subset analysis comparing AML/ALL of either groups individually; AML (40% *versus* 29.16%, p= 0.3262) /ALL(22.2% *versus* 18.18%, p=0.7019).The CR rates in the baseline uninfected group *versus* in the baseline infected group was 78.78% *versus* 61.11% respectively in ALL and was 39.58% *versus* 36.66% in AML and neither of the difference was statistically significant.

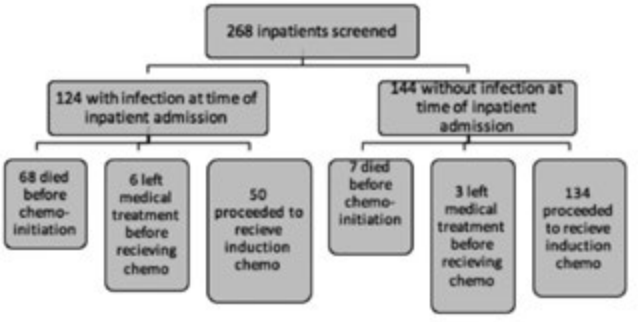

Figure 1.

Summary/Conclusion: Patients with infection at baseline demonstrating clinical improvement upon treatment with antibiotics/antifungals can be considered for induction chemotherapy. There is need for studies using newer therapeutic agents with potentially lower disruption of muco-cutaneous barriers, lower myelotoxicity and potential infliction of lesser physiological stress as a bridge to subsequent full dose induction chemotherapy in these patients infected at baseline even prior to the initiation of chemotherapy.

PB1731

OUTCOME PREDICTION OF AML PATIENTS SUBMITTED TO ALLOGENEIC STEM CELL TRANSPLANTATION IN RECENT YEARS. A SINGLE CENTER EXPERIENCE ON 101 PATIENTS

N. Polverelli[1,*], V. Cancelli[1], M. Malagola[1], A. Turra[1], E. Morello[1], F. Cattina[1], B. Rambaldi[1], L. Gandolfi[1], S. Bernardi[2], F. Re[2], C. Zanaglio[2], E. Dereli[2], D. Russo[1]

[1]Unit of Blood Diseases and Stem Cells Transplantation, Department of Clinical and Experimental Sciences, University of Brescia, ASST Spedali Civili di Brescia, [2]Laboratorio CREA (Centro di Ricerca Emato-Oncologica AIL), ASST Spedali Civili di Brescia, Brescia, Italy

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) represents the most effective therapy for high risk acute myeloid leukemia (AML) patients. Due to its morbidity and mortality, patients' selection is crucial. Several prognostic score are used to define the pre-HCT risk for AML patients, however most of them are dated or difficult to be applied in clinical practice.
Aims: To evaluate the clinical outcome of AML pts submitted to allo-HCT.
Methods: Clinical and laboratory data of 101 AML patients submitted to allo-HCT from October 2006 to June 2017 at the Stem Cells Translantation Unit of Spedali Civili Hospital in Brescia were retrospectively collected. A multivariable model was used to weight parameters associated to lower survival post-HCT, in order to build a prognostic score.
Results: The clinical features of the cohort were the following (median):age 52y (18-67), ≥55y, 47%; male, 56%; AML with myelodysplasia related changes (7%); therapy-related (9%). Karyotype was normal in 39%, unfavorable in 54% and favorable in 7% of cases. Seventeen patients (17%) had FLT3-ITD, 20 (20%) NPM1 and 5 (5%) CEBPA mutations. WT1 gene was overexpressed in 56% of patients. ELN risk category was low/intermediate 1 in 41 (40%), intermediate-2/unfavourable in 60 (60%) patients, respectively.Twenty-one patients (21%)presented chemo-refractoriness to induction treatment; 81(80%) were submitted to allo-HCT in complete hematological remission. Allo-HCT was performed after a median time from diagnosis of 9 months (range, 3-118), conditioning regimen was myeloablative in 55% of cases; matched-related donor was employed in 43 cases (43%), matched-unrelated in 44 (44%), and alternative in 14 (13%) cases. Peripheral blood was the most frequent source of stem cells (73%). According to Sorror HTC-CI, 6 (6%) patients presented 0, 20 (20%) 1, 10 (10%) 2 and 65 (64%) 3 or higher score. Seventy-two patients had a Karnofsky (KPS) equal to 90-100, 29 (28%) pts<90. After a median follow-up of 31 months (range, 6-133) from allo-HCT, acute and chronic graft *versus* host disease (GVHD) were encountered in 38% and 20% of patients, respectively. At last follow-up, 55 patients (54%) died, for a 2-year overall survival (OS) of 51%. Causes of death were related to: allo-HCT complications (TRM) (30%), disease relapse (66%), other unrelated in 4% of cases, respectively. Among baseline features, age ≥55 years (p=0.03), disease-persistence at transplantation (p<0.001), induction chemotherapy refractoriness (p=0.001), and KPS<90 (p<0.001) significantly correlated with higher mortality. Notably, no differences were observed according to HCT-CI (p=0.096). In multivariate analysis, age ≥55 (HR 2.3 CI95% 1.3-4), disease status at transplantation (HR 2.2 CI95% 1.04-4.8) and lower performance status (HR 2.6 CI95% 1.2-5.4) confirmed their negative prognostic association. Based on these HR, a weighted score was developed; accordingly, age received 2 points, disease-persistence 2 points and KPS 3 points. Low (0 points), intermediate (2-3 points) and high risk (>3 points) categories were so projected to an OS of 74%, 54% and 10% at 2 years, respectively (p<0.0001)(figure 1).

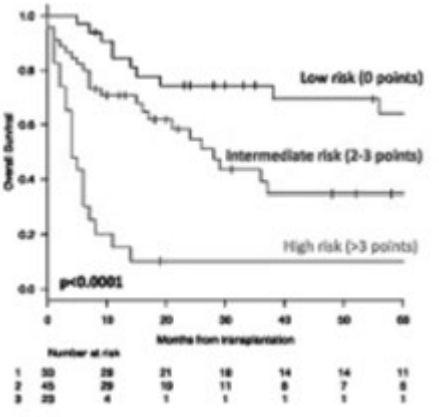

Figure 1.

Summary/Conclusion: In our experience, advanced disease and performance status were the most important prognostic factors for allo-HTC. With the limitations of the retrospective nature of the study and the number of enrolled patients, our simple clinical score seems to predict allo-HCT outcome in AML patients. Further larger studies are needed to confirm these preliminary data.

PB1732

FEASIBILITY AND EFFICACY OF INTENSIVE SALVAGE TREATMENTS FOR ELDERLY PATIENTS WITH RELAPSED ACUTE MYELOID LEUKEMIA

B. Massimo[1,*], M. Carrabba[1], C. Messina[1], F. Pavesi[1], L. Vago[1], B. Gentner[1], R. Milani[2], S. Mastaglio[1], F. Lorentino[1], G. Casirati[1], F. Ciceri[1]

[1]Haematology and BMT Unit, [2]Flow-cytometry and Cell-manipulation lab, San Raffaele Scientific Institute, Milan, Italy

Background: outcome of AML patients (pts) older than 60 years is poor because of unfavourable disease characteristics and of comorbidities, frequently tailoring under-powered treatment. The complete remission (CR) rate after intensive treatments is lower than in younger pts, with relapse incidence and mortality associated to treatment (TRM) being higher. Rarely, elderly pts who relapse after initial remission receive salvage treatments aiming to obtain further disease remission.
Aims: to evaluate the feasibility and efficacy of intensive treatments in our elderly pts with relapsed AML.
Methods: retrospective analysis of data from 50 pts with AML in CR relapsed between 2/2002-1/2018. Criteria for pts selection to receive salvage treatments: PS (ECOG) ≤2, renal and hepatic parameters within normal ranges or<2 times normal values, no active infections and cardiac ejection fraction >50%.
Results: median pts age at relapse was 70 (61-81). Cytogenetics and molecular data at relapse were available only for a minority of pts and were not analyzed. Median time to relapse was 227 days (range 42-3369). Overall, 30 pts (60%) received at least one reinduction treatment: chemotherapy (CHT) in 23 cases, upfront allogeneic transplantation (alloSCT) in 3 cases, alloSCT after no response to CHT in 4 cases. Eleven pts had previously received an autologous SCT, 19 pts CHT with intermediate or high dose cytarabine, as consolidation of first CR. Twenty-one pts (68%) obtained

second CR (CR2), 15 after CHT alone, 3 after upfront alloSCT, 3 after CHT and alloSCT. TRM was 27% (8 pts), overall, 17% after CHT alone, 75% after upfront alloSCT, 50% after CHT and alloSCT. Of the 15 pts in CR2 after CHT alone, 10 did not receive further treatments, 5 received an alloSCT. At last follow up 4 pts out of 30 (13%) are alive in CR2, with a median survival from relapse of 421 days (255-4906). Median OS from relapse of all pts who received any reinduction treatment was 276 days (33-4904). Median OS from relapse of pts who obtained the CR2 750 days (137-4904). Median DFS from CR2 was 429 days (29-4848).

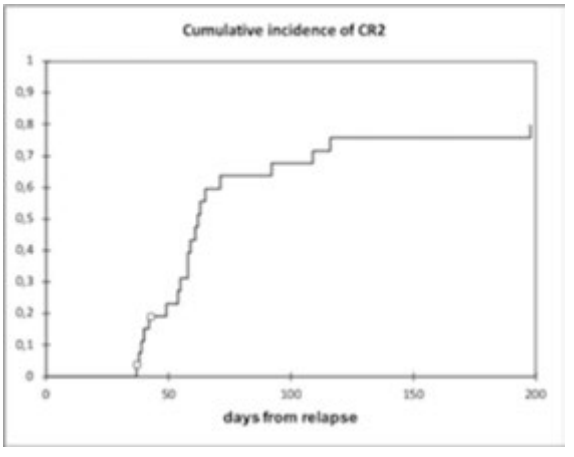

Figure 1.

Summary/Conclusion: intensive reinduction approaches proved feasible in our elderly pts with relapsed AML. The CR rate was similar to that obtained at diagnosis. Actually, TRM was high, in particular after alloSCT (57% overall). Of note, 4 pts (57%) had active disease at time of alloSCT. Moreover, median age of the treated population was high. Anyway, several pts obtained prolonged overall and disease free survival. We conclude that elderly pts with relapsed AML, fit according to PS and general criteria, could benefit from an intensive curative approach. Recent introduction of new strategies to prevent and treat potentially fatal complications after alloSCT, in particular infections and graft *versus* host disease, should prospectively reduce TRM and improve survival.

PB1733

RISK FACTORS AND OUTCOMES OF PATIENTS WITH RELAPSED CORE-BINDING FACTOR-POSITIVE ACUTE MYELOID LEUKEMIA

M. Virijevic[1,2,*], M. Mitrovic[1,2], Z. Pravdic[2], A. Novkovic[3], V. Djordjevic[2], N. Suvajdzic[1,2], A. Vidovic[1,2], D. Tomin[1,2]

[1]Faculty of Medicine, University of Belgrade, [2]Clinic for Hematology, Clinical Center of Serbia, [3]Clinical Hospital Center Zemun, Belgrade, Serbia

Background: Core-binding factor-positive acute myeloid leukemia (CBF-AML) (t(8;21) or inv(16)/t(16;16)) is associated with favorable prognosis. However, first relapse of AML-CBF occurs in 30% to 40% patients and can still be cured in half of patients. A number of studies identify predictive factors of outcome in relapsed CBF-AML which may help to improve post-relapse therapy strategies.
Aims: to determine risk factors for relapse in CBF-AML and to report clinical outcome of relapsed CBF-AML.
Methods: his single-center study involved 74 patients with *de novo* AML with rearrangement of CBF genes during the period between January 2006 and December 2017. We assessed clinical, biological, histological and cytogenetic characteristics for relapse and outcome of relapsed CBF-AML. Risk factors were identified using univariate and multivariate analysis. Kaplan-Meier method is used to estimate overall survival (OS).
Results: Among the 74 CBF-AML patients, 21 (28.4%) patients relapsed. Median age at relapse was 52 years (range, 28-64 years); inv(16) had 5/21 (23.8%) and t(8;21) 16/21 (76.2%) of patients) The median duration for CR1 was 20 months (range, 1-132 months) for inv(16) and 12 months (range, 1-120 months) for t(8;21) (p=0.051). Univariate analysis detected the following significant risk factors for relapse in CBF-AML: age ≥50 years (p=0.039), CD56$^+$ (p<0.001). Multivariate analysis identified CD56$^+$ as the most important risk factor for relapse in CBF-AML (p=0.001; relative risk (RR)=0.59; 95% confidental interval (CI)=0.011-0.308). The median OS for all the patients after relapse was 24 months (2-132 months); 25 months (range 2-132 months) for those with inv(16) and 18 months (range, 3-132 months) for those with t(8;21) (p=0.551). The CR2 rate for the inv(16) and the t(8;21) was 80% and 53.3%, respectively (p=0.630). Univariate analysis detected the following significant risk factors for poor OS in relapsed CBF-AML patients: elevated LDH (p=0.05), CD56$^+$ (p=0.05) and t(8;21) (p= 0.045). Multivariate analysis identified t(8;21) as the most important risk factor for poor OS in relapsed CBF-AML (p=0.045; relative risk (RR)=3.171; 95% confidental interval (CI)=0.891-11.283).
Summary/Conclusion: According to the results obtained from the analysis, CBF-AML with CD56$^+$ have a higher risk of relapse. Among patients with relapsed CBF-AML, the outcome was worse in patients with t(8;21).

PB1734

FEASIBILITY AND SAFETY OF AN EARLY INTENSIFICATION APPROACH WITH FLAG-IDA IN NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA (AML) PATIENTS WITH MORPHOLOGICAL RESIDUAL LEUKEMIA AT DAY 14 BONE MARROW AFTER 3+7

F. Pavesi[1,*], M.G. Carrabba[1], C. Messina[1], F. Lorentino[1], E. Sala[1], G. Casirati[1], C. Liberatore[1], L. Vago[1], R. Milani[2], P. Ronchi[3], B. Gentner[1], F. Ciceri[1], M. Bernardi[1]

[1]Hematology and BMTUnit, [2]Flow Cytometry and Cell manipulation lab, [3]Immunohematology and Transfusion Medicine, San Raffaele Scientific Institute, Milan, Italy

Background: 3+7 chemotherapy (CT) is considered reference treatment for AML patients (pts) treated with a curative intent although the rate of complete remission are lower than those that can be obtained with more intense regimens (eg FLAG-ida). Early assessment of response in AML by day 14 bone marrow (day 14 BM) has been proposed as a tool to optimize the response rate by the introduction of an early second induction in patients with >10% residual blasts. Recent data and reviews criticize this approach since day 14 BM specificity might be suboptimal and an early re-treatment be too toxic. In this context we reviewed our experience of an early intensification with FLAG-ida in pts obtaining a suboptimal response at day 14 BM after 3+7.
Aims: To evaluate the safety, the feasibility and the outcome of FLAG-ida as early re-induction for newly diagnosed AML pts treated at our hospital between february 2009 to june 2017.
Methods: Retrospective analysis of 19 consecutive newly diagnosed AML pts who were candidate to early re-induction due to residual blasts >10% (12-90%) at day 14 BM morphological examination and who were considered fit (without active infection, PS ECOG<2, without renal and/or hepatic impairments) to receive FLAG-ida. As outcomes we defined day 30 and 60 not relapsed mortality, complete remission (CR) rate at day 30 post FLAG-Ida, percentage of patient completing their intention to treat (ITT), event free survival (EFS) and overall survival (OS).
Results: Median age of our series was 60 years (26-78 years). 84% pts were de novoAML. 2 pts were ELN favorable risk, 13 intermediate and 4 adverse. Median follow-up was 669 days (248-1479 days). Median time from the induction start to FLAG-Ida was 17 days (15-23 days). After FLAG-ida median time to neutrophil recovery was 20 days (16-26 days), we recorded 2 cases of bacterial pneumonia and 2 possible invasive fungal infection which recovered with appropriate therapy. Non relapse mortality rates at 30 and 60 days from FLAG-ida were 0% and 10.5% (2/19). One pt died in CR for an adenovirus hepatitis, the other for a septic shock (from MDR Pseudomonas aeruginosa) after receiving high dose cytarabine as consolidation. Seventeen of 19 pts (89.5%) obtained the CR after FLAG-ida (median time 29 days). Two pts (10,5%) were refractory. Sixteen of these 17 (94%) pts completed treatment according to the ITT: 12 pts received allogeneic stem cell transplantation, 1 pt autologous transplantation and 3 pts consolidation chemotherapy. Twelve pts were alive when we analyzed the data, 9 of them in a durable CR. Two year EFS and OS rates were 45.6% (95% CI: 20-68.2) and 78.9% (95% CI: 53.2-91.5) respectively. (Figure 1).

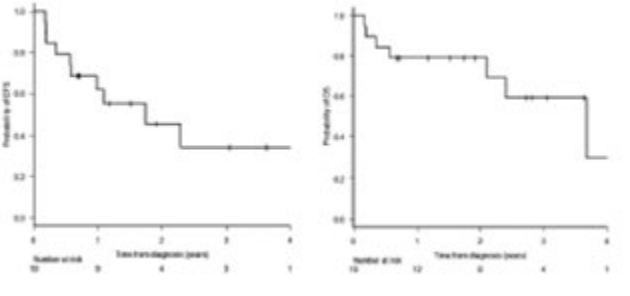

Figure 1.

Summary/Conclusion: Our findings suggest that FLAG-ida as early reinduction is feasibile and safe at least in a subgroup of AML pts selected on the basis of fitness criteria. Although recent data raise questions on day 14 BM morphology specificity we believe that our results are of relevance for designing strategies based on early residual disease (eg multi parametric flow cytometry based) assessment in AML to be tested in prospective study. The number of pts which completed the treatment in respect to the ITT and the persistent CR in spite of the prognostic value of day 14 BM suggest that a strategy of early intensification on the top of 3+7 can be considered in future clinical trials.

PB1735

REGISTRY FOR THE OFF-LABEL USE OF VENETOCLAX IN PATIENTS WITH RELAPSED OR REFRACTORY ACUTE MYELOID LEUKEMIA

R. Shahswar[1,*], I. Hamwi[1], C. Lueck[1], M. Toepperwien[1], C. Koenecke[1], W. Fiedler[2], R. Madanchi[2], J. Krauter[3], A. Trummer[3], M. Eder[1], G. Beutel[1], M. Stadler[1], S. Ehrlich[1], L. Hambach[1], A. Ganser[1], F. Thol[1], M. Heuser[1]

[1]Department of Hematology, Hemostasis, Oncology and Stem Cell Transplantation, Medical School Hannover, Hannover, [2]Department of Medicine II, Oncological Center, Hubertus Wald University Cancer Center, University Hospital Hamburg-Eppendorf, Hamburg, [3]Department of Hematology and Oncology, Klinikum Braunschweig, Braunschweig, Germany

Background: Previous data have shown promising safety and efficacy of venetoclax (VEN) in combination with hypomethylating agents (HMAs) or low-dose cytarabine (LDAC) in untreated AML patients (pts). VEN is a potent oral small molecule inhibitor of the anti-apoptotic protein BCL-2 and is currently approved for use in refractory chronic lymphoid leukemia pts.
Aims: To establish a registry of AML patients treated with VEN off-label and to report initial results.
Methods: Patients with refractory or relapsed (R/R) AML who were treated with VEN at three German medical centers were included. Patients received VEN for salvage treatment in combination with HMAs or LDAC outside of a clinical trial. We retrospectively collected data regarding clinical, genetic and treatment characteristics. All patients had given informed consent to the off-label use of VEN, genetic analysis and use of clinical data according to the Declaration of Helsinki.
Results: Eight patients with R/R AML who received salvage treatment with VEN in combination with HMAs or LDAC were eligible for analysis. Median age was 68 years (range 41-78). The patient cohort had an unfavorable risk with 5 pts (63%) having secondary or therapy-related AML, 7 (88%) pts being treated in second or higher salvage therapy (range 1-4), 3 (38%) pts having adverse ELN risk, 7 (88%) pts having received prior HMA or LDAC therapy and 1 (12%) patient having received prior allogeneic stem cell transplantation (SCT). In 6 of 8 pts (75%) VEN was combined with azacitidine (n=5) or decitabine (n=1), in 2 pts (25%) it was combined with LDAC. The VEN dose ranged from 50 to 600 mg per day with dose reduction related to concomitant CYP3A4 inhibitor treatment, primarily azole antifungals, in 6 pts (75%). At data cutoff pts received a median of 2.5 cycles (range 1-7, one patient ongoing). Of the 7 patients who discontinued VEN, reasons included progressive disease (n=3), death in aplasia due to sepsis (n=1) and transition to SCT (n=3). The overall response rate (ORR), defined as complete response (CR) or CR with incomplete blood count recovery (CRi) or partial response (PR) per IWG criteria was 6/8 (75%, 1 CR, 3 CRi, 2 PR with peripheral blood count recovery). All 6 patients treated with dose-reduced VEN because of concomitant azole use achieved a response. Three pts were successfully bridged to transplant. Median follow up was 9.4 months. Median survival was 6.6 months. Five patients died (63%), 3 from progressive disease and 2 from infectious complications. Transfusion-dependent anemia (n=8) and thrombocytopenia (n=6) were common prior to the start of therapy. Four of 8 patients (50%) achieved red blood cell transfusion independence. Three of 6 patients (50%) achieved platelet transfusion independence with recovery of platelet counts to >50/nl after a median of 36 days (range 29-47). One pancytopenic patient only received VEN on days 1-14 of each cycle in combination with LDAC and achieved complete blood count recovery after the second cycle (PR).
Summary/Conclusion: We established a clinical registry for R/R AML patients who were treated with VEN. Results are comparable to other reports of off-label use in R/R AML patients. Efficacy of VEN was maintained after dose reduction for concomitant azole treatment. Continuous VEN dosing may result in long lasting cytopenias, which may require dose interruptions. Including patients treated with off-label VEN in a registry can help us to better understand this novel treatment.

PB1736

OUTPATIENT-BASED HIGH DOSE CYTARABINE FOR PATIENTS WITH ACUTE MYELOID LEUKEMIA: SAFE, FEASIBLE AND COST EFFECTIVE APPROACH

P. Kaloyannidis*, E. Shaibani, F. Aburahma, A. Ferrer, J. Abiera, S. Kanfar, O. Abduljalil, K. Bakhit, A. Suhebeh, R. Khalili, A. Abualruz, O. Qariesh, J. Apostolidis, K. Al Anezi, H. Al Hashmi

Adult Hematology and Stem Cell Translantation Department, King Fahad Specialist Hospital, Dammam, Saudi Arabia

Background: Effective treatment of acute myeloid leukemia (AML) includes the induction remission therapy which is followed by consolidation chemotherapy. Regimens for consolidation are as intensive as induction therapy, and in the most centers are usually given in an inpatient basis, for 2-3 cycles, lasting approximately for a total of 3–4 months. Given the practical considerations such as healthcare costs and limited inpatient resources and the current advantages in the supportive care post chemotherapy, the administration of consolidation treatment in an outpatient basis emerges as an appealing approach.
Aims: In this study we evaluated the feasibility and safety of high dose Cytarabine (HiDAC) as consolidation treatment in an outpatients basis
Methods: Sixteen patients of a median age 48,5 (17-64) years who met the eligibility criteria (good compliance, general health status WHO: 0-1, no severe preceding or residual infections, timely reach the hospital services) received in a total 20 cycles of HiDAC (2g/m^2 intravenously over 3 hours infusion, twice daily for 3 days); 4 patient received 2 cycles of HiDAC. All patients received orally prophylaxis against bacterial, viral and fungal infection started from the 1st day of chemotherapy infusion till blood-counts recovery. GCSF was not given routinely for neutrophils recovery. Chemotherapy and supportive care were given in an allocated room in our department. Patients and their relatives had been previously informed in details regarding the consequences and the potential risks of chemotherapy. Patients were closely monitored (every 1-2 days) in the outpatient clinic
Results: All the 20 cycles successfully completed and no severe side effects occurred during chemotherapy infusion; patients mainly complained for nausea and mild vomiting which fully controlled with the appropriate treatment. The median day for neutrophils (>500/mm^3) and platelets (>20000/mm^3) recovery were +21 (19-24) and +23 (19-26) after HiDAC treatment. Only 3 /16 patients were admitted for a total of 13 days (5, 5 and 3 days respectively), for neutropenic fever of unknown origin. All cases promptly responded to the treatment and no patient admitted to intensive care unit.
Summary/Conclusion: Our study demonstrated that HiDAC can be safely given in an outpatient basis, provided that the aforementioned eligibility criteria are met. The extremely short hospitalization period (13 days for the total of 20 HiDAC cycles) resulted in lower exposure to nosocomial pathogens, saving also significant inpatients beds. Keeping also in mind that the inpatient administration of HiDAc usually requires at least 20 hospitalization-days per cycle, we can easily conclude that the outpatient approach of HiDAC chemotherapy offers also significant cost effectiveness.

PB1737

DOES THE ICU ADMISSION OF THE *de novo* AML PATIENTS DURING REMISSION INDUCTION HAVE INFLUENCE ON THE LONG-TERM OUTCOME?

A. Bazhenov*, G. Galstyan, E. Parovichnikova, V. Troitskaya, M. Drokov, V. Savchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: Treatment of acute myeloid leukemia (AML) is associated with high rate of the life-threating complications requiring intensive care unit (ICU) admission. The long-term outcomes of AML pts discharged from ICU are widely discussable and generally unknown.
Aims: To compare the overall and the disease free survival in *de novo* AML pts who did not require and those pts who required admission to ICU during remission induction.
Methods: All *de novo* AML pts, younger than 60 yo, who were treated in NRC from 2013 to 2015 yy, were enrolled into the study evaluating the impact of ICU admission on the long-term outcomes. Median age was-34 yo (20-60 yo). Patients had advanced disease: LDH activity median 767u/l (263-5152u/l); 76% of *de novo* AML pts had ECOG score 3-4 [1]. Patients were divided into 2 groups: 1st (n=24)-pts who were required ICU admission during induction chemotherapy due to life-threating complications and emergency events and 2nd (n=33)-pts who did not require ICU admission

during induction chemotherapy. 3 years overall survival (OS) and disease free survival (DFS) were assessed by the Kaplan-Meier method, log rank value $p<0.05$ consider as significant. Univariate analysis was performed with $\chi 2$ tests or Fisher's exact tests for categorical variables to find an independent ICU mortality predictor. All calculations and graphics were performed on IBM SPSS Statistics.

Results: 42% (24 of 57 pts) were admitted to the ICU due to life-threating complications and emergency events during induction chemotherapy. All *de novo* AML pts admitted to ICU were characterized by very advanced disease: LDH activity median 1056 u/l; 25% pts with WBC more than $100x10^9$/l; 35% pts of adverse cytogenetic group,-in comparison with pts who did not require admission to ICU: LDH activity median 689 u/l; 15,8% pts with WBC more than $100x10^9$/l; 18% pts of adverse cytogenetic risk. Reasons for ICU admissions were the following: acute respiratory failure (ARF) - 50%; acute neurological event-19,2%; septic shock (SS)-11,5%; urgent caesarian section-11,5%; arrhythmia-7,8%. ICU survival rate was 75%. 5 pts died due to the SS and 1 due to the ARF. Need for mechanical ventilation, need for vasopressors, 2 and more organ dysfunction were independent significant predictors of ICU mortality ($p<0.05$). A landmark analysis for OS was performed for patients who survived the first 30 days of treatment (1st induction chemotherapy cycle). OS and DFS were the similar in 1st and 2nd groups; p (log rank) =0.946 and p (log rank)=0.339 n.s. (picture 1 a, b).

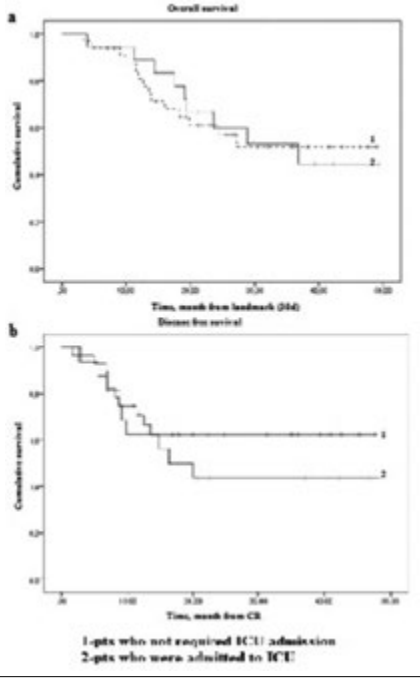

Figure 1.

Summary/Conclusion: There is no significant difference between 2 groups (ICU requires and non-requires) in OS and DFS. The successfully treated life-threating complications had no influence on the long-term outcomes.

REFRACTORY/RELAPSED ACUTE MYELOID LEUKEMIA PATIENTS WITH HIGH CD117 EXPRESSION BUT WITHOUT FLT3-ITD MUTATION COULD BE A SPECIAL GROUP WITH GOOD RESPONSES TO SORAFENIB TREATMENT ALONE

J. Xu[1,*], B. Wu[2], X. Liu[3], Y. Zhong Yuxia[4]

[1]Hematology Department, Zhujiang Hospital, Southern Medical University, Guangzhou, [2]Hematology Department, Shunde Hospital of Southern Medical Universtiy, Shunde, [3]Hematology Department, the Trusted Hospital of Panyu, Panyu district, Guangzhou, [4]Clinical Laboratory Department, Zhujiang Hospital, Southern Medical University, Guangzhou, China

Background: There are great unmet needs to explore more efficient and low-cytotoxic treatment for refractory or relapsed acute myeloid leukemia (R/R AML) patients. CD117 high expression was reported to be related with higher relapse of AML. But its inhibitors, such as imatinib or dasatinib, were not reported to successfully treat R/R AML by now. Because sorafenib targets multiple tyrosine kinases including CD117, and it has been reported to successfully treat R/R AML patients with FLT3/ITD mutation as a single agent. Here we retrospectively investigated the outcomes of seven R/R patients with high CD117 expression but without FLT3/ITD and C-kit mutation treated with single sorafenib.

Aims: The aims of this study is to see if sorafenib treatment alone could benefit this special group of patients with high CD117 expression but without FLT3/ITD and C-kit mutation.

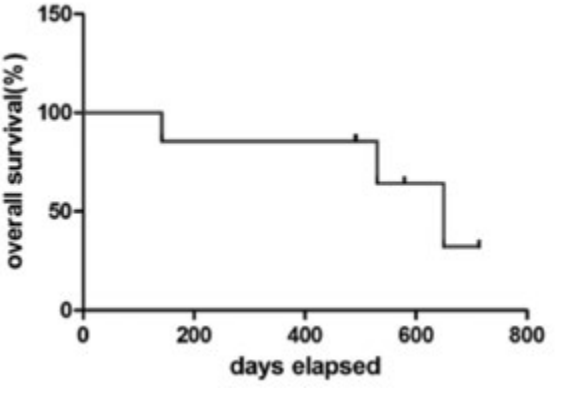

Figure 1.

Methods: Seven R/R AML patients without FLT3-ITD or C-kit mutations who were treated by single sorafenib, 0.4 gram twice a day, were sequentially enrolled in our center from May 2015 to August 2016. CD117 were positively expressed on more than 60% of bone marrow blast cells. Diagnosis was made according to the category criterion of WHO 2008. The risk status assessments and standards of patients' responses were referred to the NCCN guideline. Side effect grade was named according to common terminology criteria for adverse events v 4.0 by US National Institutes of Health. The outcomes of patients were followed up till September 2017.

Results: Four of the 7 patients achieved CR or CRi with single sorafenib. The time required to remission ranged from 31 to 100 days variably. In other three NR patients, two could also have a temporary decrease of bone marrow blast cells in the first week, but all had increment of blast cells in the latter two to three weeks and prescription of sorafenib went to cease. During sorafenib induction, all patients experienced grade 3 febrile neutropenia but had no unendurable infections. One patient developed grade 3 palmar-plantar erythrodysesthesia at the day 54. But it tapered in one week after stopping the drug. The median follow-up for the whole cohort have been more than 17 months. Three patients passed away for relapse of AML and their event free survival with sorafenib ranged from 2 to 20 months. All four patients who accepted stem cell transplantation were still alive at the end of follow-up no matter they responded to sorafinib or not. The median survival time initiating from sorafenib usage has been 650 days.

Summary/Conclusion: The preliminary study on single sorafenib treatment responses of R/R AML with high CD117 expression and no FLT3-ITD mutation gave an encouraging result. Sorafinib, at least as a bridge to transplantation, should be considered in such special R/R AML patients in further study.

DO LEUKAPHERESIS IMPROVE EARLY DEATH RATES IN ACUTE MYELOID LEUKEMIA PATIENTS WITH HYPERLEUKOCYTOSIS?

O. Ilhan*, G. Cengiz Seval, A. Uslu, S. Civriz Bozdag, S.K. Toprak, M. Kurt Yuksel, P. Topcuoglu, O. Arslan, M. Ozcan, T. Demirer, H. Akan, M. Beksac, G. Gurman

Hematology, Ankara University School of Medicine, Ankara, Turkey

Background: Hyperleukocytosis (HL) is defined as the clinical condition when the white blood cell (WBC) count is above 100 000/mm^3 in peripheral blood and the reported incidence of HL is between 5 and 20% in acute myeloid leukemia (AML). The effect of leukapheresis on early mortality data is scarce.

Aims: The aim of this study was to investigate the effect of leukapheresis on early mortality of AML patients with HL
Methods: From January 2005 through October 2017, data from 70 patients with AML who were eligible for leukapheresis were evaluated. All these data were obtained from the Ankara University Faculty of Medicine Center for Therapeutic Apheresis and written informed consent was signed according to our institution regulations. All leukapheresis procedures were performed according to the institutional standard operating procedures after informed consent. Leukapheresis was performed with a continuous-flow blood cell separator (COBE Spectra; TerumoBCT, software version 7.0) via central venous access. The leukapheresis procedures were continued on a daily basis until clinical improvement was determined. Early mortality was defined as death within the first 15 days of leukapheresis.

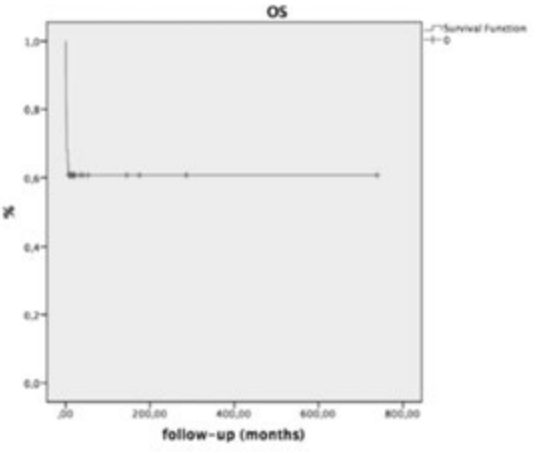

Figure 1.

Results: The study cohort consisted of 70 (36 male/33 female) newly diagnosed AML patients who had presented with HL and/or symptoms of leukostasis and underwent leukapheresis. The median age was 52 years (range, 4–86 years). The median WBC counts at diagnosis was 179.2x10^9/L (range, 56.5-558.0x10^9/L). The majority of patients, 88.6% (n=62) had WBC count ≥100x10^9/L. The majority of patients had symptoms of pulmonary leukostasis. A total of 140 leukapheresis cycles were performed among the 70 AML patients. The median number of leukapheresis cycles was 2 (range, 1–7). The median initial WBC was 179.2×10^9/L, which reduced to 121.7x10^9/L after the first leukapheresis. Eleven of the seventy patients had died by the time of analysis. Seven patients (10%) died within two weeks after leukapheresis commenced. Among the 7 patients, one patient was treated with induction chemotherapy and the remaining received palliative and supportive care. The main cause of early death was respiratory failure. The mean overall survival for all patients was 112±17 months (95% CI 78–145 months) (Figure). The median overall survival for patients who achieved complete all-cause 2-week mortality rate was 10% (7/70 patients) and the all-cause 4-week mortality rate was 12.8% (9/70 patients).
Summary/Conclusion: Leukapheresis is effective and safe procedure in reducing the peripheral blood leukocytes and leukemia blasts. Furthermore, high initial response rates in a subgroup of newly diagnosed AML patients fit to receive intensive chemotherapy suggest that leukapheresis could be beneficial in reducing the complications associated with hyperleukocytosis until systemic intensive chemotherapy commences.

PB1740

DETECTION OF PML-RARA IN APL: COMPARING FISH, PCR AND CONVENTIONAL KARYOTYPING

M. Pereira[1,*], G. Marques[2], R. Reis[2], A. Sousa[2], S. Pereira[2], N. Jerónimo[2], R. Tomé[2], F. Martins[2], L. Jorge[2], L. Ribeiro[1], F. Rodrigues[2]

[1]Clinical Hematology Department, [2]Clinical Pathology Department, Coimbra University Hospital, Coimbra, Portugal

Background: "Acute promyelocytic leukemia (APL) with PML-RARA" (WHO, 2016) is characterized by the presence of the aforementioned fusion gene, classically secondary to the t(15;17)(q24.1;q21.2) translocation, although cases of variant or cryptic translocations have been described. The presence of the translocation and its fusion product can be identified by conventional karyotyping (CK), interphase FISH analysis using adequate probes, and molecular biology (MolB) through polymerase chain reaction (PCR), three techniques with different sensitivities, advantages, disadvantages and limitations, that have been well described in the literature.
Aims: We aim to compare the outcome of the simultaneous application of the three techniques in a real-world setting.
Methods: We reviewed all peripheral blood (PB) or bone marrow aspirate (BM) samples that were analysed in our lab over a five-year period (from January 1st 2013 to February 14th 2018) for a suspected diagnosis of APL at presentation or relapse, and that were submitted for near simultaneous testing using at least two of the three techniques. Samples that were submitted for analysis but that were not processed due to a limitation of the sample (such as insufficient volume), were counted as not analysed. Results were classified as "positive" or "negative" for the translocation. Abnormal karyotypes that nevertheless did not reveal the classical t(15;17) translocation or one of its variants were considered "negative" in this context.
Results: Over the timeframe under consideration, 55 patients underwent a combination of two or more of the techniques at diagnosis or suspected relapse: 87.3% had FISH analysis (14.6% in a full unsorted mixed-cellularity BM or PB sample, and 85.4% in fluorescence-activated cell sorting (FACS)-separated APL blast cells); 65.4% had MolB testing; and 67.3% underwent conventional karyotyping. Overall, 22.9% of patients had all three tests, 37.5% had FISH + MolB and 39.6% had FISH + CK. Only two samples were negative for all three tests. All MolB and CK testing results were fully concordant. Likewise, all negative MolB results were also negative by FISH; however, 11.1% of positive MolB results were negative by FISH, k=(-1.0), p=1.00; half of these samples were submitted for conventional karyotyping and were positive for the translocation. All samples with a normal karyotype had a negative FISH test; all abnormal karyotypes without a t(15;17) translocation were negative by FISH; however, 12.5% of abnormal karyotypes with a detectable t(15;17) translocation were also negative by FISH (and positive on MolB), k=(-0.3), p=0.88. In all the above discordant cases, both morphology and cellular immunophenotyping by flow cytometry were not diagnostic for APL, and FISH probe hybridization had been performed on FACS-sorted cells; all cases were suspected relapses.
Summary/Conclusion: In our cohort, molecular biology and conventional karyotyping results were fully concordant, with a lower rate of detection for FISH analysis, where approximately 10% positive samples by MolB and CK were undetected, always in the context of a low disease burden, as evidenced by a normal BM smear and immunophenotype, and in a suspected relapse. FACS-separation of blast cells, especially when the immunophenotype failed to identify these cells as pathologic APL blasts, does not appear to be of benefit and may, in fact, have hindered the detection of the fusion gene by FISH.

PB1741

AZACITIDINE OR DECITABINE FRONTLINE THERAPY FOR ACUTE MYELOID LEUKEMIA IN ELDERLY PATIENTS?

S. Imbergamo*, A. Visentin, I. Kostic, S. Pravato, E. Scomazzon, M. Laurino, G. Binotto, F. Lessi, T. Berno, C. Gurrieri, G. Semenzato, L. Trentin

Department of Medicine, Hematology and Clinical Immunology Unit, Padua University School of Medicine, Padova, Italy

Background: Acute myeloid leukemia (AML) is a rare aggressive hematologic disease that occurs most often in the elderly and treatments for these patients are limited, particularly in those with poor performance status (PS) and comorbidities. Poor prognosis of elderly AML patients is due to several factors, including comorbidities, decreased organ function, poor performance status and a higher incidence of adverse karyotype. Although intensive chemotherapy can bring a high rate of complete remission (CR) in elderly AML patients, the toxicity and fatal side effects limit its extensive application in elderly unfit patients. Recent updated on AML treatment recommendations include hypomethylating agents 5-azacytidine (AZA) and decitabine.
Aims: The aims of this study were the comparison the two hypomethylating agents and the evaluation of the overall survival (OS) of Azacitidine and Decitabine in patients with AML, not eligible for intensive chemotherapy.
Methods: A retrospective analysis was performed on 64 patients with AML, 39 treated with Azacitidine and 25 treated with Decitabine, followed at Padua University Hospital from April 2012 to February 2018. The diagnosis was made according to 2016 WHO criteria. Thirty-nine patients received s.c. 5-Azacitidine 75mg/m^2 for 7 days every 4 weeks until disease progression, and twenty-five patients received e.v. Decitabine 20mg/m^2 for 5 days every 4 weeks until disease progression.
Results: The median age at diagnosis was 70 years (range 49-83). Eighteen patients (46%) were considered at high, 19 (48%) intermediate and 2 (6%) low-cytogenetic risk in the AZA group, while twelve (80%) patients were

considered at high, 3 (12%) intermediate and 2 (8%) low-cytogenetic risk in the Decitabine group. The complete remission was reached in 37% patients in AZA group, and in 30% in Decitabine group. The median OS for the AZA cohort was 10.7 months, while the median OS for the Decitabine cohort was 6.9 months, without any difference (p=0.9980). The median PFS for the AZA cohort was 4.4 months, while 11 months for Decitabine cohort, without any difference (p=0.2469). In univariate analysis, the variable associated with increased OS was adverse cytogenetic-risk (p=0.0367) in AZA cohort, not reaching in Decitabine cohort. No significant differences comparing the two treatments in patients with and without unfavorable cytogenetics-risk were found. Myelosuppression was the most common toxicity observed in decitabine treated patients. Infection-related complications occurred in 35 patients, 21 (54%) patients in azacitidine cohort and 18 (72%) patients in decitabine cohort. Pneumonia (62%) and sepsis (9%) were the most frequent infectious complications. These latters may occur during any cycle of therapy.
Summary/Conclusion: In conclusion, in our study there were no significant differences between azacitidine and decitabine. These agents are an effective and well-tolerated therapeutic alternative with acceptable side effects in elderly AML patients.

PB1742

THE ROLE OF MUTATIONS OF THE GENE FLT3 IN ACUTE MYELOID LEUKEMIA: THE EFFECT ON THE COURSE OF THE DISEASE AND THE RESULTS OF THE THERAPY

A. Radzhabova[1,*], S. Voloshin[1], I. Martynkevich[2], A. Kuzyaeva[3], V. Shuvaev[3], E. Motyko[3], L. Polushkina[3], M. Buckeye[3], N. Potikhonova[3], A.R.S. Kudryashova[3], V. Balashova[3], J. Chubukina[3], O. Uspenskaya[4], A. Chechetkin[3], M. Zenina[3]

[1]Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency, Federal State Budget Institution, [2]Federal State Budget Institution, Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency, [3]Federal State Budget Institution "Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency", Federal State Budget Institution "Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency", [4]Leningrad regional clinical hospital, Saint-Petersburg, Leningrad regional clinical hospital, Saint-Petersburg, St-Petersburg, Russian Federation

Background: Acute myeloid leukemia (AML) is an aggressive disease with extremely poor prognosis. Radical treatment like conventional chemotherapy (CT) +/– allogenic hematopoietic stem cell transportation (allo-HSCT), is rarely considered in elderly patients due to age, comorbidities and poor somatic state. The presence of mutations of the *FLT3* gene (*ITD* or *TKD*) in AML is recognized as an adverse prognosis affecting the course of the disease, the development of relapses with decrease in overall survival (OS) and disease-free survival (DFS) of patients. Despite the high incidence of mutations *FLT3-ITD* and *FLT3-TKD*, the role of the allelic load of the mutant gene *FLT3* has not been completely identified. Up to date we have no clinical studies with treatment individualized to elderly AML patients. The introduction of target therapy in AML gives hope for diminishing treatment side effects ang prolongation of life for elderly frail patients with AML.
Aims: To assess the frequency of *FLT3* gene mutations and their influence on clinical manifestations, relapse rate, OS and DFS of patients with AML.
Methods: A retrospective study of the incidence of *FLT3* gene mutation in blood or bone marrow and clinical outcomes in 199 AML patients (83 males) was conducted. Median age at the time of diagnosis was 52 years (20-86 years). The polymerase chain reaction (PCR) method with further restriction and determination of 2 main mutation types-internal tandem duplication (*FLT3-ITD*) and point mutation in "A-loop" (*FLT3-TKD*) was used to evaluate the *FLT3* status.
Results: The incidences of *FLT3* gene mutations were as follows: *FLT3-ITD*-22,6% (45/199), *FLT3-TKD*-5,5% (11/199), *FLT3-ITD* and *FLT3–TKD* in combination-1,0% (2/199); the rest-70.8% (141/199) patients did not have any mutation in the FLT3 gene (FLT3–). Complete blood counts have statistical significant differences in the white blood cells (p=0.0009) and the blast percent (p=0.01) between FLT3(-) and FLT3(+) patients. Chromosomal abnormalities were revealed in 38% (17/45) patients of *FLT3-ITD+* group, 64% (7/11)-*FLT3-TKD+* and in51% (72/141) of *FLT3–* cases. Both *FLT3-ITD/TKD+* patients had normal karyotype,. No significant (p=0.2990) differences have been yielded in the duration of OS between groups of patients with normal karyotype and chromosomal aberrations, regardless of the presence or absence *FLT3* gene mutations. The presence of *FLT3-ITD+* mutation was associated with higher risk of AML relapse (p=0.00006) than *FLT3-TKD+* or *FLT3(-)* patients. All patients received various CT regimens depending on age, performance status and comorbidity (7+3, 5+2, HAM). We observed significant (p=0.00024) differences in the OS between *FLT3*-ITD+, *FLT3-TKD+* and *FLT3–* patients. Median OS were: 5.1 months for *FLT3-ITD+*; 7.1 months for *FLT3-TKD+* and 13.0 months for *FLT3–* patients. Univariate analysis showed the next adverse factors for OS: any *FLT3* gene mutation (p=0.00007) and fail to achieve remission (p=0.000001). Factors influencing DFS were as following: karyotype at disease onset (favorable, intermediate and unfavorable) (p=0.013), the presence of *FLT3* mutations (p=0.0000013) and type of mutation (p=0.0001).
Summary/Conclusion: *FLT3* mutations in AML patients give adverse prognosis for OS and DFS. There is urgent need to have molecular genetic markers screening in the AML workup at initial diagnosis and risk-adapted therapy choice.

PB1743

OUTCOME OF ELDERLY PATIENTS WITH ACUTE MYELOID LEUKEMIA IN A SINGLE INSTITUTION

A. García-Noblejas*, E. Jiménez-Barral, A. Arriero, J. Cannata-Ortiz, A. Figuera, R. De La Cámara

Hematology, Hospital La Princesa, Madrid, Spain

Background: In order to cure Acute Myeloid Leukemia (AML) intensive chemotherapy +/- Stem Cell Transplant (SCT) is require. Nevertheless, the median age of these patients is around 70 years. Elderly patients, defined in the AML literature as aged ≥60 years, historically have lower complete remission (CR) and relapse-free survival (RFS) rates than their younger counterparts and, in practice, only a minority of them can receive intensive treatments. For the majority of patients, the options are demethylating agents or supportive care.
Aims: To analyze the outcome of AML patients ≥60 years old according to the different therapeutic approach in a single institution. ts, defined in the AML literature as aged ≥60 years, historically have lower complete remission (CR) and relapse-free survival (RFS) rates than their younger counterparts and, in practice, only a minority of them can receive intensive treatments. For the majority of patients, the options are demethylating agents or supportive care.
Methods: Unicentric, retrospective analysis of AML patients ≥60 years old, not treated previously and diagnosed from 2011 to 2016. Statistical analysis was performed using SPSS v.15.0.

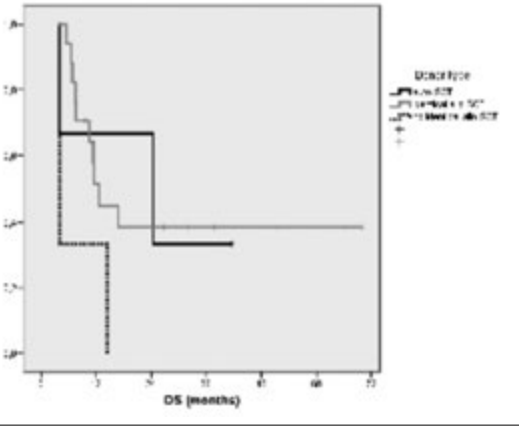

Figure 1.

Results: Patients' characteristics: Sixty-nine patients were registered: 51% male, median age 69 years old (range 60-90), 87% ECOG ≤1, 52% *de novo* and 48% secondary, and 22% with monosomal or complex karyotype. 49 patients (71%) received induction chemotherapy, 6 patients (9%) demethylating agents, only one patient (1%) received chemotherapy plus demethylating agents and 13 (19%) supportive care. Among patients treated with chemotherapy (n=49), 23 patients (47%) received consolidation with SCT (19 allogenic and 4 autologous) and 13 (26%) received demethylating maintenance. **Survival:** Median follow-up for alive patients was 42 months (range 4-81 months). Median overall survival (OS) from diagnosis according to the initial treatment was: 17 months (CI95% 10-23) for patients treated with chemotherapy (n= 49), 9 months for patients treated with demethylating agents (n=6) (CI95% 0-25), 8 months for the only patient who received chemotherapy plus demethylating agents and less than 1 month for those that received supportive care (n=13) (p<0.001). For patients treated in induction with chemotherapy, neither age (60-69 *vs* 70-79), type AML (de novo

vs secondary), FLT-3 mutation, or SCT as consolidation (allogenic or autologous) have an impact in overall survival. Nevertheless, no complex/monosomic karyotype (p=0.01) and receiving demethylating maintenance (p=0.02) were associated with a better outcome. Patients treated in induction with chemotherapy plus maintenance with demethylating agents compared with those that received SCT, were older (p<0.001) but showed no differences in the main characteristics of their leukemia (secondary, karyotype and FLT3). Median overall survival in transplanted patients (n=23) was as follows: 24 months for auto-SCT (n=3), 12 months in HLA-identical related/unrelated SCT (n=17) and 4 months in haploidentical or mismatched HLA unrelated SCT (n=3) (p=0.1). Both auto-SCT and identical allo-SCT observed plateau in survival graphics (**Figure 1**).
Summary/Conclusion: Our study shows the outcome of 69 older patients with AML in our current practical clinical. If patients are fit induction chemotherapy seems to be the best option to achieve longer outcomes but the post-induction isn't clear and have to be personalised.

PB1744

REAL LIFE SINGLE CENTER EXPERIENCE WITH TREATMENT REGIMENS IN ADULT PATIENTS WITH ACUTE PROMYELOCYTIC LEUKEMIA-EARLY DEATH RATES (2002-2018)

I. Oravcova[1,2,*], E. Mikuskova[1], L. Demitrovicova[1], S. Cingelova[1], V. Mikudova[1], S. Kevicka[1], A. Slobodova[1], A. Mlcakova[3], J. Gyarfas[3], M. Mego[1,2], L. Drgona[1,2]

[1]Oncohematology, National cancer Institute, Bratislava, Slovakia, [2]Oncohematology, Faculty of Medicine Comenius University, [3]Laboratory Hematology, National cancer Institute, Bratislava, Slovakia, Bratislava, Slovakia

Background: An integral part of the initial treatment of acute promyelocytic leukemia (APL) is a supportive treatment of hemorrhagic diathesis. Early death (ED) either before or during induction treatment remains the most frequent cause of failure in the treatment of APL. The induction death rate within the first month of ATRA treatment ranged between 5%–10% in clinical trials, however in real-life non-selected patients the ED rate ranged between 17%–30%. The most frequent reason of ED is fatal intracranial (57%–62%) or alveolar hemorrhage or both.
Aims: Some adverse prognostic factors are known being in correlation with ED and some are still being studied. We analyzed biologic and laboratory characteristics of patients with APL in relation to ED.
Methods: Eligible patients were adults, at least 18 years of age with *de novo* APL. Risk group was set according to Sanz *et al.* predicting model. ED was the death from any cause during induction. Patients were treated progressively over the years by the Spanish treatment protocol (LPA96, LPA99, LPA2005) and from the June 2017 by the Intergroup Study Protocol (GIMEMA + DSIL, APL 0406), which means that the induction treatment till June 2017 consists of ATRA and anthracycline for all risk groups and thereafter consists of ATRA and ATO for low and intermediate risk group, while high risk group continues the induction ATRA + anthracycline + cytarabine. All patients were analyzed for: sex, age, leukocytes, thrombocytes, blasts in peripheral blood (PB) and bone marrow (BM), lactate dehydrogenase (LDH), HLA-DR and CD56 expression, fibrinogen, PT and APTT, additional chromosomal abnormalities and PML/RARA type of transcript in relation to ED. For survival evaluation were used log-rank test (Kaplan-Meier) and Fisher exact test was used for early death risk factor analysis.
Results: 24 patients with APL were diagnosed and treated from 10/2002 to 1/2018. Two patients died till 12 hours after admission to the hospital (46 years old and 20 years old woman with initial clinical signs of intracerebral bleeding at the time of initial investigation, both started treatment of APL) and they were excluded from the survival assessment. We observed totally six ED (25%), representing 66.7% of total APL deaths. Five (25%) of them due to hemorrhagic event, four (16.7%) patients had intracerebral hemorrhage and 1 patient had intrapulmonary hemorrhage. One patient died of tumor lysis syndrome. 17 (70.8%) patients achieved first complete molecular remission, two patients died in relapse and one woman had primary myelosarcoma of the breasts, APL subtype, she didn t achieved complete remission and refused any treatment after induction as well and died. At median time of follow-up 46 month (0.16–159 months) the estimated 3-year OS and RFS were 77.0% CI 95% (59.3%–94.7%) and 71.9% CI 95% (52.7%–91.1%) respectively. In univariate analysis the prognostic factor that most influenced survival were the number of leukocytes ≥$10x10^9$/l (p=0.018), blasts in PB ≥70% (p=0.007), PT-INR >1.5 (p=0.001), APTT ≥35s (p=0.014). Risk factors associated with early death were: Le ≥$10x10^9$/l (p=0.015), blasts in PB ≥70% (p=0.001), PT-INR >1.5 (p=0.001), LDH >4μkat/l (p=0.002) and presence of bcr3 transcript (p=0.033).
Summary/Conclusion: Hemorrhagic events are the main cause of ED. Quick transport to hematologic center treating APL, recognizing high risk patients and supportive treatment are crucial for favorable outcome. Outcome of APL patients in our center is comparable to the results reported as real life data or from cancer registries.

PB1745

EARLY MORTALITY IN ACUTE MYELOID LEUKEMIA WITH HYPERLEUKOCYTOSIS

A. Moicean*, R. Billström

Hematology, Dept of Medicine M[1], Skaraborgs Hospital, Skövde, Sweden

Background: Age and cytogenetic/mutational leukemia cell profile are the most important determining factors for long-term survival after therapy in acute myeloid leukemia (AML), whereas the adverse factor elevated white blood cell count (WBC) at diagnosis is often linked to high early mortality.
Aims: Assessment of early mortality
Methods: In a community hospital covering a population of 255000, 67 out of 116 adult patients with newly diagnosed non-APL AML received combination chemotherapy aiming at complete remission (CR) during the time period 2007-2016. We assessed 30-day mortality in the subgroups with WBC 51-100x10E9/l (N=5, 8%) and >100x10E9/l (N=7, 10%, range 126-402x10E9/l), respectively, at diagnosis.
Results: No early deaths were observed in the WBC 50-100 group. In contrast, 2 out of 7 with WBC >100 died day 16 (WBC 126, liver failure) and day 18 (WBC 312, septicemia), respectively. Remarkably, two of the 7 patients with WBC>100 including a 28-year old male with a spectacular WBC 402x10E9/l, are among the long term survivors at 42+ mo and 90+ mo.
Summary/Conclusion: Leukocytosis >50,000 is not defining for early mortality (in the first 30 days) in non-APL AML. Extreme leukocytosis (WBC >100) does not affect survival if applied with a therapeutic strategy with a curating but protective purpose to avoid acute complications of treatment (such as leukostasis, progressive disseminated intravascular coagulation or acute tumor lysis syndrome). We discuss strategies to avoid complications such as the late insertion of the central venous catheter or another cytostatic sequence during induction for AML with extreme leukocytosis. This strategy replaces leukopheresis that was previously recommended for these cases and allows for an effective and rapid reduction in leukemic tumor mass.

PB1746

RARE REPORT OF PROMYELOCYTIC SARCOMA AFTER RENAL TRANSPLANT

L.-J. Shen*, F.-Y. Chen, J. Hou, H.-H. Huang, X. Gao

Hematology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

Background: Promyelocytic sarcoma (PS) following renal transplantation is an extremely rare phenomenon. Here we report a 26-year-old male suffered with PS at the site of transplanted ureter six months after renal transplant. Bone marrow aspiration and biopsy were normal, but Bcr1 subtype (intron 6) of the PML/RARα rearrangement gene was showed positive with 0.005 through common myeloid leukemia associated mutation genes and fusion genes screening. Chromosome was 46, XY. Flow cytometry detection of bone marrow cells had no special found. Then, fluorescence *in situ* hybridization (FISH) for PML/RARα rearrangement was performed on the ureteral tumor and it suggested positive at 15q22/17q21.
Aims: As the lesion seemed to be limited in the transplanted tissue, we sought to determine whether the tumor was a transmission of cancer from organ donor to the recipient.
Methods: In order to address this hypothesis, DNA was extracted from the excised ureteral mass and compared with DNA from the patient's blood. Just like as we suspected, DNA by short tandem repeat analysis revealed that ureteral mass was not of recipient origin. The young donor was died from cerebral hemorrhage. We proposed that she may be suffered from disseminated intravascular coagulation, which is the severe and common complication of acute promyelocytic leukemia.
Results: Chemotherapy (arsenic trioxide 0.15mg/kg/d on d1–28, and ATRA 40mg/d for 28 days) was administered to induce remission. Immunosuppression therapy was changed into rapamycin single agent. One month later, PML/RARα fusion gene from bone marrow sample was negative. Thereafter he received arsenic trioxide five days a week with 0.15mg/kg/d for 4 weeks every 8 weeks, and ATRA 40mg/d on d1-14 every 28 days for 28 weeks as the post-remission therapy recommended by Lo-Coco F published in New England Journal of Medicin. This patient maintains complete remission for nearly 2 years. Now his renal function sustains on a normal level and the

urinary tract is unobstructed. Till now, the other recipient of this deceased donor's kidney hasn't caught by tumor.

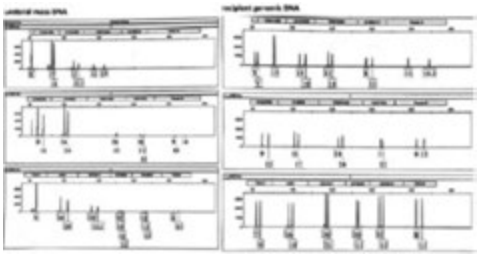

Figure 1.

Summary/Conclusion: Malignancy, as a major complication of renal transplant, accounts for 20% of the exitus of renal transplant patients every year and accounts for 30% of the death causes of the renal transplant recipients with a follow-up greater than 20 years. PS in the complete absence of bone marrow disease is an extremely rare phenomenon. To our knowledge, there had been only 2 patients presenting with promyelocytic sarcoma following renal transplant in the past three decades. They both suffered kidney failure again and subsequently had an allograft nephrectomy during the following chemotherapy. Management of recipients with *de novo* cancers after transplantation is complex and difficult. Recommendations for cancer screening in the renal transplant population (including donors and recipients) were mostly extrapolated from the general population. It's better to reduce the intensity of the combined chemotherapy and adjust immunosuppression therapy to protect the function of fragile allograft once *de novo* tumor occurred.

PB1747

INTENSIVE INDUCTION TREATMENT OF ACUTE MYELOID LEUKEMIA IN PATIENTS AGED ABOVE 60 IN SHATHD BETWEEN 1.01.2010 AND 1.01.2018, PROGNOSTIC FACTORS FOR INDUCTION MORTALITY

S. Lozenov[1,*], V. Stoeva[2], Y. Petrov[1], S. Mishkarova[1], Z. Popova[1], G. Arnaudov[1], B. Spassov[1]

[1]NSHATHD, [2]NSHATHD, Sofia, Bulgaria

Background: Acute myeloid leukaemia is an oncohaematological disease, with an incidence rate increasing with age. The patients aged above 60 years represent more than 60% of all cases, but the results from the treatment in this age group are worse and the therapeutic approaches available are more limited. With induction mortality rates with standard 7+3 based regimens reaching above 20% in some series one of the most difficult questions in this subset of patients is the proper assessment of the "fitness" of the patients.
Aims: We aimed to assess the therapeutic results from the intensive treatment of AML patients 60 years and older, concerning their overall survival and induction mortality rates and also to identify prognostic factors related to the induction mortality rates in the population of patients which was considered "fit" for intensive 7+3 based induction regimen.

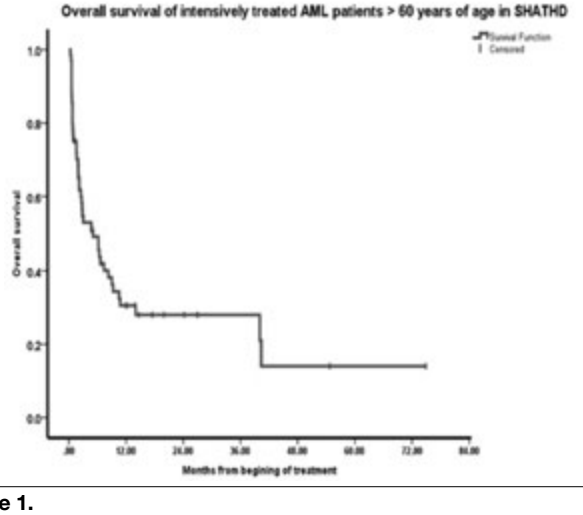

Figure 1.

Methods: 70 patients aged above 60 years with AML, diagnosed and treated intensively for AML in the period from 1.01.2010 to 1.01.2018 were evaluated in the SHATHD (Specialized hospital for active treatment of haematological diseases), with a median of the age of the analysed population of 66 +- 4.08. The treatment consisted of 7+3 based regimens including at least 5 days of administration of Ara-C at a dose above 100 mg per day and at least two administrations of an anthracicline at a standard dose (Epirubicin, Mitoxantron, Idarubicin). We evaluated the overall survival of the patient population, some of the conventional prognostic factors at diagnosis-serum albumin, creatinine, bilirubin, leukocyte count, platelet count, cytogenetic and molecular anomalities, percentage of blast infiltration in marrow, underlining MDS/MPP, some comorbidity indexes (Charlson Comorbidity Index, HCT-CI) and the levels of inductions mortality (IM) rate for the intensively treated patients, defined as mortality within 28 days from the commencing of treatment. The statistical methods used include the methods of Kaplan-Meier, Chi-Square, Fisher's exact test and Non-parametrical analyses between categorical and continuous variables conducted on the software product SPSS version 22.0.
Results: The OS within the study population is 28% at the second year and 14% at he fifth year. The level of the induction mortality as defined above stands at 21.42%. The analysis of the factors with prognostic significance for induction mortality in patients treated with 7+3 based regimens revealed strongly significant impact of platelet count on induction mortality (p 0.002), pretreatment levels of albumin and creatinine were also significantly affecting prognosis for induction mortality (p 0.028, p.0.030). The lassociation of AML with MDS/MPP also exposed the patients to a significantly higher risk of IM (p. 0.002), while the presence of cytogenetic or molecular aberration correlated with lower risk of IM (p 0.025). Interestingly in our studied population CCI and HCT-CI did not have statistically significant impact on IM.
Summary/Conclusion: The increase of the age for intensive treatment of elderly AML patients and the increasing transplant activity in these patients is a global trend now. In order to achieve significantly better results in terms of overall survival, new prognostic systems with a better potential for controlling the treatment related mortality and better selection of the "fitness" of patients for intensive treatment, are needed. This will probably require the development of expected IM risk calculators specific for the elderly patients with AML and their specific risk factors.

PB1748

IMPACT OF BONE MARROW ASPIRATE TREGS ON THE RESPONSE RATE OF YOUNGER NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA PATIENTS

M. Delia*, P. Carluccio, A. Mestice, C. Brunetti, F. Albano, G. Specchia

University of Bari-Bari, Italy, Hematology and Bone Marrow Transplantation Unit, Bari, Italy

Background: Acute myeloid leukemia (AML) is widely considered as a distinct clinical entity with a well-defined molecular and genetics-based prognosis. Particularly, in the younger patient the therapeutic approach depends largely on diagnostic risk stratification, which has an impact on the outcome after therapy.
Aims: We have added T regs evaluation to the usual molecular and cytogenetics profile in the AML younger patients diagnostic bone marrow aspirate (dBMA) in order to look for any correlation between Tregs and overall response (OR) as well as survival (OS) rates.
Methods: The study included 19 AML patients (12 males and 7 females, median age 57 years, range 20-65) all treated with "3+7" regimen. According to cytogenetic-molecular risk stratification: 2 (11%), 9 (47%) and 8 (42%) patients were assigned to the favorable, intermediate and adverse prognosis groups, respectively. Molecular evaluation (*i.e.* NPM; FLT3; CEBPA) was performed in all cases: NPM1 (A or B mutation) and FLT3 mutations (ITD or D835) were positive in 3 (16%) and 3 (16%) patients, respectively. There were no CEBPA positive cases. Median values of white blood cells (WBC) were 10400/uL and of dBMA Tregs 21/uL.
Results: OR (Complete remission (CR) + CR incomplete (CRi)) was documented in 7 of 19 patients (37%); there were two partial responderpatients. The optimal dBMA-Tregs cut-off value for predicting response to treatment (>21/uL) was obtained by ROC curve analysis. Apart from the expected impact of the molecular/cytogenetic group (p=0.05) and the NPM mutation (p=0.036), OR was also correlated with dBMA Tregs >21/uL (p=0.020). Furthermore, the same Tregs value seemed to correlate with a better median OS (21 *vs* 4 months, Log-Rank test, p=0.028).
Summary/Conclusion: Obviously, the possible prognostic value in terms of OR and survival rates of such an immunological player as BMA Tregs should be confirmed in larger patients numbers

PB1749

CORRELATION OF INTERLEUKIN-6, INTERLEUKIN-10, AND TRANSFORMING GROWTH FACTOR BETA SERUM LEVELS WITH THE RESPONSE TO INDUCTION CHEMOTHERAPY IN NEWLY DIAGNOSED ACUTE MYELOID LEUKEMIA PATIENTS

T. Salah[1,*], Z.A. Abdelhafez[2], M.A. Abdou[2], M.M. Salah Eldeen[2,] S.M. Mansour[3], S. Mabrouk[4]

[1]Clinical Oncology Department, [2]Clinical Pathology Department, Assiut faculty of medicine, Assiut university, [3]Clinical pathology department, South Egypt cancer institute, Assiut university, [4]medical oncology department, South Egypt cancer institute, Assiut university, assiut, Egypt

Background: Cytokines are involved in the pathogenesis of acute myeloid leukemia (AML) but their prognostic significance in these diseases is unknown. In this study, We assessed the association between changes in serum levels of interleukin-6, interleukin-10, and transforming growth factor beta cytokines baseline and after induction chemotherapy and the response to induction chemotherapy in patients with recently diagnosed previously untreated Acute Myeloid Leukemia (AML) patients.
Aims: To Assess the serum levels of IL-6, IL-10 and TGF beta in different types of newly diagnosed acute myeloid leukemia patients (FAB classifications) and the relationship between these cytokines and the laboratory findings and To determine the pre-and post-induction levels of these cytokines and their relationship to bone marrow blast cells.
Methods: This is a prospective case control study carried out on patients from Hematological Diseases Unit in internal Medicine Department, Assiut University Hospital and Medical Oncology Department, South Egypt Cancer Institute and clinical oncology and nuclear medicine department, Faculty of medicine, Assiut university. This study recruited 30 newly diagnosed patients with AML diagnosed by WHO classification and sub-classified (M1-M6) by FAB classification from February 2016 to May 2017. Mean age of the patients was 44 years (20-68). 30 patients (12 males and 18 females) as well as 20 age and sex matched healthy controls were also enrolled. Blood samples and estimation of serum levels of studied cytokines were collected from patients before induction and recollected again 10-14 days after induction and results were compared to its serum levels in 20 healthy control group (20 healthy individuals).The study was approved by the ethical committee of Faculty of Medicine, Assiut University. Informed Consents were obtained from the patients before enrollment in this study.
Results: Baseline serum levels of IL-6 and IL-10 levels were significantly higher in newly diagnosed AML patients than in control group (P-value=0.000*) suggesting their role in pathogenesis of the disease and their levels decreased when patients underwent remission (bone marrow blast cells count<5%),with significant decrease in both responders and non-responders for IL-6 but regarding IL-10 there was a significant decrease only in responders (P-value=0.012*) and insignificant decrease in non-responders (P-value=0.2) .On the other hand, baseline TGF-β level was significantly lower in newly diagnosed AML patients (before induction chemotherapy) than control group and its level significantly increased in patients responded to induction chemotherapy (P-value=0.012*) and insignificant increase in non-responders(P-value= 0.227).
Summary/Conclusion: Persistant Increased Serum level of IL-10 and persistant decreased TGF-β level may be used as a prognostic marker for AML indicating poor response to induction chemotherapy and unfavorable prognosis.

Aggressive Non-Hodgkin lymphoma – Clinical

IS DA-EPOCH -/+ RITUXIMAB FOR AGGRESSIVE LYMPHOMA FEASIBLE AND EFFECTIVE IN CLINICAL PRACTICE? A RETROSPECTIVE STUDY

S. Matsuda[1,*], Y. Suehiro[2], N. Tomita[3], K. Izutsu[4], N. Fukuhara[5,] Y. Imaizumi[6], K. Shimada[7], T. Nakazato[8], I. Yoshida[9], T. Takahashi[1,] R. Suzuki[1], M. Yamaguchi[10], J. Suzumiya[1]

[1]Cancer center, Shimane University Hospital, Izumo, [2]Hematology, National Hospital Organization Kyushu Cancer Center, Fukuoka, [3]Hematology, St. Marianna University School of Medicine, Kawasaki, [4]Hematology, Toranomon Hospital, Tokyo, [5]Hematology, Tohoku University Hospital, Sendai, [6]Hematology, Nagasaki University Hospital, Nagasaki, [7]Hematology, Nagoya University Hospital, Nagoya, [8]Hematology, Yokohama Municipal Citizen's Hospital, Yokohama, [9]Hematologic Oncology, National Hospital Organization Shikoku Cancer Center, Matsuyama, [10]Hematology and Oncology, Mie University Graduate School of Medicine, Tsu, Japan

Background: CHOP is the standard chemotherapeutic regimen for aggressive lymphomas. CHOP with rituximab (R) therapy is the standard of care for newly diagnosed diffuse large B-cell lymphoma (DLBCL), but it is not sufficient for DLBCL with adverse prognostic factors. Excellent efficacy of dose-adjusted (DA)-EPOCH -/+ R therapy has been reported for primary mediastinal large B-cell lymphoma (med DL), Burkitt lymphoma, and peripheral T-cell lymphomas (PTCLs). A phase II study on DA-EPOCH-R/high-dose methotrexate therapy for untreated stage II-IV CD5+ DLBCL also demonstrated promising efficacy (Miyazaki *et al.* ASH2016). However, the feasibility and efficacy of DA-EPOCH -/+ R in clinical practice has not been fully evaluated.
Aims: To evaluate the feasibility and efficacy of DA-EPOCH -/+ R for aggressive lymphomas in clinical practice, we conducted a retrospective study.
Methods: We retrospectively analyzed clinical features and outcomes of 149 patients with aggressive lymphoma who received DA-EPOCH -/+ R between 2007 and 2015 in 17 institutes in Japan.
Results: The patients' characteristics were as follows: male, 55%; median age, 62 years (range, 17-87); >65 y.o, 44%; no prior treatment, 60%; DLBCL, 54%; ECOG PS >1, 35%; and stage III/IV, 78%. All patients were hospitalized, and a central venous catheter was used in 96% of patients. The maximum dose level of DA-EPOCH was<1 in 13% of patients, level 1 in 57%, level 2 in 11%, level 3 in 13%, and >3 in 7%. The median number of cycles was 4 (range, 1-8). There was no treatment-related death. Grade 3/4 febrile neutropenia, infection, and constipation were documented in 54%, 28%, and 6% of patients, respectively. In elderly patients (≥65 y.o), these were 60%, 32%, and 9%, respectively. Only constipation (all grades) and neutropenia (grade 3/4) occurred more frequently in elderly patients than in younger patients. Patients with newly diagnosed DLBCL-NOS (*n*=46) exhibited the following clinical features: median age: 65 years (range, 28-87); >65 y.o, 50%; male, 50%; ECOG PS >1, 46%; and stage III/IV, 83%; IPI high/high intermediate, 73%; CD5+, 49%. The median follow-up duration was 23.9 months (range, 2.2-79.9). CR and estimated 2-year OS rates were 80% and 81%, respectively. There was no difference in OS according to dose levels of DA-EPOCH-R. The estimated 2-year OS rate for med DL (*n*=14) was 100%.
Summary/Conclusion: These results suggest that DA-EPOCH -/+ R is feasible in clinical practice and safe for elderly patients. Promising efficacy of DA-EPOCH -/+ R for aggressive lymphomas was also observed in this study, warranting further evaluation.

PB1751

THE AVERAGE RELATIVE DOSE INTENSITY OF R-CHOP IS AN INDEPENDENT PROGNOSTIC FACTOR DETERMINING OVERALL SURVIVAL IN DIFFUSE LARGE B CELL LYMPHOMA PATIENTS

M. Długosz-Danecka[1,*], S. Szmit[2], T. Ogórka[1], K. Krawczyk[1], E. Łątka[1], A. Skotnicki[1], W. Jurczak[1]

[1]Department of Hematology, Jagiellonian University, Krakow, [2]Department of Pulmonary Circulation, Thromboembolic Diseases and Cardiology, Centre of Postgraduate Medical Education, European Health Centre, Otwock, Poland

Background: Prognosis of diffuse large B cell lymphoma (DLBCL) patients depends on lymphoma and patient-related risk factors, best summarized in

IPI (International Prognostic Index). The aim of the study was to determine whether the average relative dose intensity (ARDI) of anthracycline containing regimen could be an IPI-independent prognostic factor.T

Aims: The aim of the analysis was to assess the relationship between the calculated ARDI and PFS and OS in DLBCL patients treated with R-CHOP chemotherapy.

Methods: We analysed 223 white Caucasian DLBCL patients, who completed at least four cycles of first-line R-CHOP immunochemotherapy (Rituximab, Doxorubicin, Cyclophosphamide, Vincristine, Prednisone). ARDI was calculated by specially developed software, in each individual patient, simultaneously with chemotherapy prescription. It allowed to address instantly all revealed causes of decreased ARDI. Importance of ARDI for progression-free/overall survival (PFS/OS) was evaluated.

Results: ARDI was decreased due to prolonged interval between immunochemotherapy cycles caused by neutropenia and infections (absolute neutrophil count<1,0x10^9/l) in 49.32% (110/223) or reduction of cytostatic doses in 19.73% (44/223) patients mainly as the consequence of cardiotoxicity or neutropenia (85,18% and 14,81% respectively, estimating in the group of patients with reduced doses of cytostatics). Progression free and overall survival (PFS and OS) varied significantly for ARDI >90%, 89-80% and<80% respectively (p<0.00001). Multivariate analysis confirmed that ARDI>90% was an IPI independent predictor of prolonged PFS (Hazard Ratio (HR), Confidence Interval (CI): HR=0.31; 95%CI: 0.20-0.47; p<0.000001) and OS (HR=0.32; 95%CI: 0.21-0.48; p<0.000001). Even with real time ARDI analysis it was possible to maintain it above 90% in 161 of 223 patients (72%). Further improvement may be possible only after implementing primary neutropenia prophylaxis and primary cardioprotection.

Table 1. Favorable PFS and OS depending on high ARDI and low IPI (Cox proportional risk model).

Survival		ARDI >90%	low IPI (0 or 1)
multivariate analysis	PFS	HR=0.31 95%CI: 0.20 - 0.47 p<0.000001	HR=0.43 95%CI: 0.24 - 0.76 p=0.004
	OS	HR=0.32 95%CI: 0.21 - 0.48 p<0.000001	HR=0.48 95%CI: 0.27 - 0.85 p=0.01

Summary/Conclusion: DLBCL patients with ARDI >90% have significantly better outcome regardless of IPI, therefore we postulate to regard adequate dose density as an official recommendation.

PB1752

CLINICO-PATHOLOGICAL ANALYSIS OF LIMITED-STAGE DIFFUSE LARGE B-CELL LYMPHOMA RELAPSING MORE THAN FIVE YEARS AFTER INITIAL DIAGNOSIS: POSSIBLE MECHANISM OF LATE RELAPSE

T. Suzuki[1,*], S. Fukuhara[1], A. Maeshima Miyagi[2], J. Nomoto[1], K. Tajima[1], Y. Ito[1], S. Hatta[1], S. Yuda[1], S. Makita[1], W. Munakata[1], T. Suzuki[1], D. Maruyama[1], H. Taniguchi[2], K. Izutsu[1], K. Tobinai[1], Y. Kobayashi[1,3]

[1]Hematology, [2]Pathology, National cancer center hospital, [3]Hematology, International University of Health and Welfare, Mita Hospital, Tokyo, Japan

Background: A continued risk of relapse in limited-stage diffuse large B-cell lymphoma (DLBCL) has been reported (Stephens *et al. J Clin Oncol* 2016). However, the characteristics of patients (pts) who develop late relapse (LR) are not well known.

Aims: To investigate the clinico-pathological features of pts with DLBCL who develop LR and its possible mechanisms.

Methods: Of 339 pts with limited-stage (Ann Arbor stage I/II) *de novo* DLBCL diagnosed between 1997 and 2012, 21 pts who had achieved a complete response to initial therapy but relapsed after >5 years since the initial diagnosis (*i.e.* LR) underwent clinico-pathological analyses. Immunohistological analyses were performed on pts who relapsed with a DLBCL histology and whose samples were available. Cell of origin (COO) subtypes were classified by Hans algorithm. Programmed death–ligand 1 (PD–L1) expression on tumor cells and tumor-infiltrating cells (TICs) were evaluated by double staining for PAX5 and PD–L1. Cut-off values for the PD–L1(+) stain on tumor cells and TICs were 30% and 20%, respectively (Kiyasu *et al. Blood* 2015). Fluorescence *in situ* hybridization (FISH) analysis using probes mapping to 9p24.1 and centromere 9 was performed on PD–L1(+) tumor cells. The cut-off value for MYC(+) was 40%. CD163 or PD–1(+) TIC numbers were counted manually in three representative fields (0.14 mm^2 area); the average number of positive cells per unit area in samples at initial diagnosis and LR were then compared.

Results: The characteristics of the 21 pts at initial diagnosis were as follows: 60 years median age (range, 32–77); 13 (62%) had stage I disease; 12 (57%) had extranodal disease; and frequent diseases in gingival, sinonasal/nasal cavities and testes (Table). The majority of pts (n=14, 70%) had a non-germinal–center B-cell–like (non-GCB) subtype. As an initial treatment, CHOP (median, 5 cycles; range, 3–8), with (n=18) or without (n=2) radiation therapy (RT), was performed. One pt received other intensive chemotherapy. Rituximab was administered to eight pts. The median duration from initial diagnosis to LR was 7 years (range, 5–18) and the median follow-up time for survivors was 11 years. Systemic relapses (n=15, 71%) were more common than local ones. Nine pts (43%) had more than one extranodal disease; skin/subcutaneous and bone/bone marrow diseases were frequent. Of 18 pts who had received RT, 12 pts relapsed outside of the RT field only, and six relapsed both within and outside the RT field. One pt relapsed showing a composite histology of DLBCL and a low-grade B-cell lymphoma (LGBCL), and two pts relapsed with only a LGBCL histology. Four pts had a different COO subtype from that at initial diagnosis. At initial diagnosis, MYC was positive in six pts and negative in eight pts; at LR, it turned positive in five pts, all of whom relapsed with stage IV disease, although it turned negative in another five pts. Interestingly, two pts showed PD–L1(+) tumor cells at LR despite being negative at initial diagnosis. FISH analysis revealed a 9p24.1 gain in one of the two pts. More PD–1(+) TICs tended to be observed at LR than at initial diagnosis, although this was not statistically significant (p=0.13). No clear trend in the number of PD–L1(+) or CD163(+) TICs was found.

Table 1.

Table. Characteristics of 21 patients with DLBCL who developed late relapse

	At initial diagnosis	At late relapse	*P* value
Median age, years (range)	60 (32–77)	71 (45–84)	
Gender, male : female, n	12 : 9		
Ann Arbor clinical stage, I / II / III / IV, n	13 / 8 / 0 / 0	5 / 1 / 1 / 14	<0.001[1)]
Number of extranodal diseases, 0 / 1 / ≥2, n	9 / 12 / 0	2 / 10 / 9	<0.001[1)]
Site of extranodal disease, n			
Gingival	3	0	
Nasal or paranasal cavity	3	2	
Testis	3	3	
Skin or subcutaneous	0	7	
Bone or bone marrow	0	6	
Intestine or colon	0	3	
Liver	0	2	
Other sites	3	7	
Immunohistochemistry			
Cell of origin, GCB / non–GCB / NA / non–DLBCL, n	6 / 14 / 1 / 0	6 / 12 / 1 / 2	
PD–L1+ on tumor cell, + / - / NA, n*	0 / 18 / 1	2 / 16 / 1	
PD–L1+ on TICs, + / - / NA, n*	4 / 14 / 1	2 / 16 / 1	0.48[2)]
MYC expression + / - / NA, n*	6 / 8 / 5	6 / 8 / 5	
PD–1+ TIC count, median (range)*	9 (0–36.7)	13.1 (0–63.3)	0.13[1)]
CD163+ TIC count, median (range)*	12.5 (0–28.7)	9.3 (1.3–20)	0.56[1)]

*Two patients who relapsed with only a low grade B-cell lymphoma histology were excluded from the analyses. 1):by Wilcox signed-rank test, 2): by McNemar's test; DLBCL, diffuse large B-cell lymphoma; GCB, non-germinal–center B-cell–like; TIC, tumor-infiltrating cell; PD–L1, programmed death–ligand 1; NA, not applicable

Summary/Conclusion: LR patterns of advanced-stage disease, multiple extranodal diseases and non-GCB subtype were frequently seen in limited-stage DLBCL. This study suggests heterogeneity as a LR mechanism, in which, in addition to the well-known mechanism of relapse with LGBCL components, we speculate functions associated with immune evasion or cell proliferation are acquired.

PB1753

COMPARISON BETWEEN CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING AND 18F-FDG POSITRON EMISSION TOMOGRAPHY-COMPUTED TOMOGRAPHY FOR THE DIAGNOSIS OF NEUROLYMPHOMATOSIS

Y. Abe*, K. Narita, H. Kobayashi, A. Kitadate, M. Takeuchi, K. Matsue

Division of Hematology/Oncology, Department of Internal Medicine, Kameda Medical Center, Kamogawa, Japan

Background: Neurolymphomatosis (NL) is an extremely rare clinical condition and its optimal diagnostic approach remains unclear. Although pathological confirmation is the gold standard for NL diagnosis, it is often unfeasible due to the anatomical difficulty in approaching the culprit lesions and the potential risk of irreversible nerve damage caused by nerve biopsy. Contrast-enhanced magnetic resonance imaging (MRI) and fluorine-18 fluorodeoxyglucose (18-FDG) positron emission tomography-computed tomography (PET-CT) have been identified as useful modalities for the NL diag-

nosis. However, the sensitivities of contrast-enhanced (MRI) and 18F-FDG PET-CT have not been compared thus far.
Aims: We aimed to compare the usefulness and detection sensitivities of contrast-enhanced MRI and PET-CT for the diagnosis of NL.
Methods: We enrolled 18 consecutive patients diagnosed with NL between 2007 and 2018. Criteria for diagnosis of NL were as follows: (1) clinical symptoms and/or neurological findings related to the peripheral nerves, and (2) histological confirmation of lymphoma cells within the peripheral nerves or imaging findings including enlargement and/or enhancement of these nerves detected by contrast-enhanced MRI and/or abnormal accumulation of 18F-FDG in these nerves detected by PET-CT. Imaging findings of all patients were confirmed by two experienced radiologists. Detection sensitivities were compared using the McNemar test.
Results: A total of 18 patients were treated at our institution and evaluated using both pretreatment contrast-enhanced MRI and PET-CT. Of these patients, contrast-enhanced MRI identified abnormal findings in 17 (94.4%) patients, while PET-CT identified them in 12 (66.7%) patients, although the difference was slightly insignificant (P=0.074). Among the 53 involved PN, 52 (98.1%) were deemed positive for NL by contrast-enhanced MRI, whereas only 21 (39.6%) were deemed positive by PET-CT (P<0.001). Detection sensitivity of PET-CT for the cauda equine (11.1%) and lumbosacral nerves (31.0%) was lower than that of contrast-enhanced MRI. However, PET-CT and contrast-enhanced MRI showed equivalent sensitivity for detection of abnormal findings in cranial nerves (81.8%). Levels of soluble interleukin-2 receptor in patients with NL who were deemed negative for NL by PET-CT were significantly higher than in those deemed positive for NL (P=0.049). The group deemed negative for NL by PET-CT included more patients with systemic presentation of lymphoma than those deemed positive for NL by PET-CT, although the difference was not statistically significant (50.0% *vs* 33.3%, respectively; P=0.627). Additionally, patients deemed negative for NL by PET-CT had a more favorable overall survival than those deemed positive for NL (median, 37.2 *vs* 7.5 months, respectively; P=0.234). All abnormal findings for PN identified by contrast-enhanced and PET-CT in patients who responded to therapy and had follow-up imaging studies showed significant improvement, suggesting that these findings were the manifestations of neural involvements of NL.

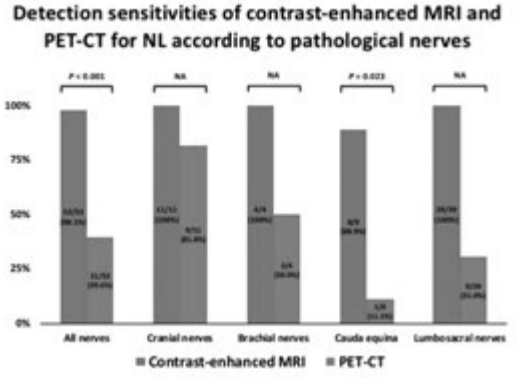

Figure 1.

Summary/Conclusion: To our knowledge, this is the first study to investigate the difference between detection sensitivities of contrast-enhancement MRI and PET-CT for the diagnosis of NL. Contrast-enhanced MRI has superior sensitivity to PET-CT for the diagnosis of NL, particularly in the cauda equine and lumbosacral nerves. Thus, contrast-enhanced MRI should be performed in combination with PET-CT for the diagnosis of NL.

PB1754

EXPRESSION AND CLINICAL RELEVANCE OF PROGRAMMED CELL DEATH-1 AND PROGRAMMED CELL DEATH LIGANDS IN EXTRANODAL NATURAL KILLER/T CELL LYMPHOMA

H. Muhamad[1,*], N. Sukswai[2], K. Wudhikarn[1]

[1]Medicine, [2]Pathology, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Background: Programmed cell death-1 (PD-1)/Programmed cell death-ligands (PD-Ls) signal plays a vital role in regulating T-cell response. Several cancers especially EBV-associated malignancy aberrantly express PD-1/PD-Ls leading to immunologic escape of tumors contributing to disease progression. In lymphoma, PD-1/PD-Ls expression was mostly described in Hodgkin lymphoma. Extranodal Natural Killer/T cell lymphoma (ENKTL) is one of the EBV-associated lymphomas more commonly found in Asia. Assessment of PD-1/PD-Ls expression in ENKTL is clinically relevant as a prognostic factor and biomarker for immune checkpoint based therapy.
Aims: To characterize PD-1/PD-Ls expression and its association with clinical characteristics and prognosis of ENKTL.
Methods: Thirty-nine ENKTL patients diagnosed at the King Chulalongkorn Memorial hospital between January 2008 and December 2017. Detailed clinical data was abstracted from medical record and immunohistochemical staining was performed on available formalin fixed paraffin embedded tissue archives to identify PD-1/PD-Ls expression within lymphoma and stromal cells. PD-L1 IHC was stained using the PD-L1 IHC E1L3N rabbit XP monoclonal primary antibody (1:400; Cell Signaling Technology, Danvers, MA, USA). PD-L2 IHC was stained using the rabbit anti-PD-L2 polyclonal antibodies (Sigma-Aldrich, St. Louis, MO, USA; catalogue# SAB3500395-100UG, used at a dilution of 1:1000). IHC staining was evaluated in agreement by two independent pathologists and two hematologists. The 5% cut-off was adopted for the positivity criteria. Clinical, pathological data and outcome were reported.
Results: Of 39 cases, median age at diagnosis was 51 years old. About half of patients presented with advanced stage and high-risk Korean ENKTL Prognostic Index (KPI). Among 33 chemotherapy treated patients, 21 (63.6%) received asparaginase based regimen. PD-L1 and PD-L2 expression were frequently presented within lymphoma cells (n=27; 69.2% for PD-L1 and n=29; 74.4% for PD-L2) with median expression of 15% and 10% respectively. Expression of PD-L1 and PD-L2 were noted on non-tumor stroma of 32 (82.0%) and 0 (0%) patients. Median stromal PD-L1 expression was 5%. PD-1 positivity within stroma was seen in 8 cases (20.5%) with median positive cells of 5% whereas there was no PD-1 expression within lymphoma cells. There was no difference in clinical features between positive and negative PD-1/PD-Ls expression except higher proportion of impaired performance status (PS) among cases with negative PD-L1 within lymphoma cells (P=0.03). There was no correlation between EBV viremia level and PD-1/PD-Ls expression. Positive PD-Ls expression within tumor cells was not associated with different EFS (2-year EFS 45.1 *vs* 54.7%; P=0.50 for PD-L1 and 42.8 *vs* 60%; P=0.31 for PD-L2) or OS (2-year OS 48.4 *vs* 74.1%; P=0.29 for PD-L1 and 51.7 *vs* 70%; P=0.36 for PD-L2). Neither PD-Ls nor PD-1 expression within stroma was associated with outcome, however, patients with positive stromal PD-1 had trend toward inferior EFS (P=0.08) (Figure 1). Univariable analysis revealed that stage, PS, KPI and asparaginase based treatment as prognostic determining factors.

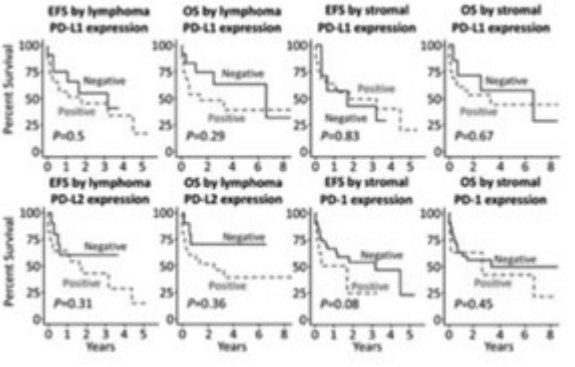

Figure 1.

Summary/Conclusion: In ENKTL, PD-Ls were aberrantly expressed within lymphoma cells at high prevalence whereas PD-1/PD-Ls were variably expressed within stroma. Our study did not demonstrate association between PD-1/PD-Ls expression and outcome, however, there was a trend toward worse EFS in patients with positive stromal PD-1. Further studies are warranted to explore significance of PD-1/PD-Ls expression in ENKTL.

PB1755

COMBINATION OF SERUM ALBUMIN AND PLATELET-LYMPHOCYTE RATIO (COA-PLR) AS A PROGNOSTIC MARKER IN PATIENTS WITH RELAPSED/REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA

Y.H. Park[1,*], J.H. Lim[2]

[1]Department of Hematology, St.Vincent's Hospital, College of Medicine, The Catholic University of Korea, Suwon, [2]Hemato-oncology, Inha University Hospital and School of Medicine, Incheon, Korea, Republic Of

Background: Recently, several inflammation-based parameters, such as lactate dehydrogenase (LDH), the neutrophil/lymphocyte ratio, the platelet/lymphocyte ratio (PLR), the absolute lymphocyte count, and serum albumin, were established for determining clinical outcomes in diffuse large B-cell lymphoma (DLBCL). However, these inflammatory parameters have been studied mainly in newly diagnosed DLBCL patients and there are few inflammation-based markers for predicting clinical outcomes of relapsed/refractory patients.
Aims: Therefore, we evaluated the usefulness of combination of serum albumin concentration and PLR (COA-PLR), as an inflammatory marker, in predicting response to salvage chemotherapy and prognosis for patients with relapsed/refractory DLBCL after R-CHOP chemotherapy.
Methods: We retrospectively reviewed data from 113 patients with relapsed/refractory DLBCL who received front-line R-CHOP chemotherapy between January 2000 and December 2016. PLR was calculated from differential count dividing the platelet measurement by the lymphocyte measurement and was recorded at first relapse or refractoriness after R-CHOP chemotherapy. A PLR of 270 was identified as the most discriminative cutoff value for overall survival (OS) and progression-free survival (PFS) from relapse or refractoriness by receiver operating characteristic curve analysis. The COA-PLR was calculated as follows: patients with both hypoalbuminemia (<3.5 g/dL) and an elevated PLR (>270) were allocated a score of 2, and patients with one or neither were allocated a score of 1 or 0, respectively.
Results: Overall, this study included 68 males and 45 females with a median age at diagnosis of 58 years (range, 23–76). Of the patients, 30 (26.5%) had refractory disease and 83 (73.5%) had relapsed disease. Of the relapsed patients, 36 (43.4%) and 47 (56.6%) showed early (≤1 year) and late relapse (>1 year) after achieving complete response (CR) or partial response (PR) at the end of R-CHOP chemotherapy, respectively. The COA-PLR score was 0 in 22 (19.4%), 1 in 55 (48.8%), and 2 in 36 (31.8%). The proportion of old patients (age >60 years) was significantly higher in the COA-PLR 2 group than in COA-PLR 1 and 0 group (61.4% *vs* 38.2% *vs* 39.5%, p<0.001). Poor Eastern Cooperative Oncology Group performance status, presence of B symptoms and high-risk international prognostic index were also observed frequently in the COA-PLR 2 group. ICE (ifosfamide, carboplatin, and etoposide) and DHAP (dexamethasone, cytarabine, and cisplatin) were the two most commonly used salvage chemotherapies resulting in overall response rate (ORR, CR+PR) of 68.1% with 46% of CR patients (n=53). The ORR after salvage chemotherapy decreased according to COA-PLR score: 82.1% at COA-PLR 0, 61.2% at COA-PLR 1, and 41.2% at COA-PLR 2 (p<0.001). Among the responders, 47 (62%) received autologous stem cell transplantation after salvage chemotherapy. Of a median follow-up of 42 months (range, 14-72), the 3-year PFS and OS rates were 32.5% and 44.2%, respectively. In multivariate analysis, early relapse (hazard ratio [HR] 2.108, 95% confidence interval [CI] 1.277-3.579), high LDH (HR 1.536, 95% CI 1.195-3.158), and COA-PLR 2 (HR 1.902, 95% CI 1.270-3.468) were independent poor prognostic factors for PFS. The independent poor prognostic factors for OS were early relapse (HR 2.104, 95% CI 1.178-3.768) and COA-PLR 2 (HR 1.976, 95% CI 1.370-2.852).
Summary/Conclusion: This study suggests that the COA-PLR maybe a potentially useful and easily available tool for predicting clinical outcomes in relapsed/refractory DLBCL patients.

RETROSPECTIVE ANALYSIS OF METHOTREXATE-ASSOCIATED LYMPHOPROLIFERATIVE DISORDERS

K. Yoshinaga*, Y. Kato, Y. Iizuka, A. Watanabe, N. Tanaka, M. Ishiyama, A. Shinohara, H. Kazama, S. Hagiwara, N. Mori, M. Shiseki, J. Tanaka

Hematology, Tokyo Women's Medical University, Tokyo, Japan

Background: Methotrexate-associated lymphoproliferative disorders (MTX-LPD) are included in category of other iatrogenic immunodeficiency-associated LPD in WHO 2016 classification. Although tumor regression by MTX discontinuation without any additional treatment is often observed, proportion of these phenomenon remains unclear. Risk factors for MTX-LPD development, and appropriate treatment strategy have not been well-known.
Aims: We conducted a retrospective observational study to characterize MTX-LPD and to evaluate prognostic factors.
Methods: We reviewed laboratory data and medical record of the pathologically confirmed MTX-LPD patients between Jan 2012 and Dec 2016 in our hospital.
Results: A total of 31 patients (23 females and 8 males; median age 71 years old, ranging 41-87 years old) were included in this study. Median observation period was 27.4 months (range 1.0-62 months). Histological diagnoses were as follows: 21 diffuse large B-cell lymphoma, 4 follicular lymphoma, 3 T-cell lymphoma, 2 Marginal zone lymphoma, one NK/T cell lymphoma. Spontaneous tumor regression within 3 months after MTX discontinuation was observed in 16 (51%) patients. Nine of them maintained remission without any additional therapy for MTX-LPD. Remaining seven patients received chemotherapy because of regrowth of LPD. Totally, 21 patients received chemotherapy. Median duration from the diagnosis to chemotherapy initiation was one month (range 3 days-38.6 months). Complete response and partial response was obtained in 11 (61%) and 5 (28%) patients. Therefore, overall response rate was 16/18(88%). Estimated 1-year overall survival (OS) rate was 93% and 3-yr OS rate was 69%. Kaplan-Meier plots demonstrated that following clinical variables were associated with worse OS: older age (65 years or older) (3-years OS, 52% *vs* 93%, log rank test, P=0.0019), higher serum LDH (>upper limit of normal range) (3-year OS, 62% *vs* 100%, log rank test, P=0.034), lower serum albumin (<3.8g/dL) (3-year OS, 42% *vs* 85%, log rank test, P=0.063), higher IPI risk categories (High-Int, and High risk groups) (3-year OS, 70% *vs* 80%, log rank test, P=0.024), and poorer performance status (PS score, 2 or higher) (3-year OS, 25% *vs* 80%, log rank test, P=0.012).
Summary/Conclusion: In conclusion, 10 (32%) patients were alive without chemotherapy after MTX discontinuation. Older age, higher serum LDH, higher IPI risk categories, and poorer PS predict survival of patients with MTX-LPD.

PROGNOSTIC SIGNIFICANCE OF TRYPTOPHAN CATABOLISM IN NEWLY DIAGNOSED DIFFUSE LARGE B-CELL LYMPHOMA

A. Masaki[1,*], S. Kusumoto[1], Y. Maeda[2], T. Narita[1], A. Ito[1], S. Kinoshita[1], T. Yoshida[1], M. Ri[1], H. Komatsu[1], T. Ishida[3], H. Inagaki[1], R. Ueda[4], S. Iida[1]

[1]Hematology and Oncology, Nagoya City University Graduate School of Medical Sciences, [2]Laboratory of Hospital Pharmacy, Nagoya City University Graduate School of Pharmaceutical Sciences, Nagoya, [3]Division of Hematology and Oncology, Internal Medicine, School of Medicine, Iwate Medical University, Morioka, [4]Tumor Immunology, Aichi Medical University School of Medicine, Nagakute, Japan

Background: Indoleamine 2,3-dioxygenase 1 (IDO1, IDO) is an enzyme catabolizing tryptophan (Trp) into the kynurenine (Kyn), and is a tumor microenvironment factor that suppresses antitumor immune responses. IDO is an attractive target for malignant tumor immunotherapy.
Aims: This study determined the prognostic significance of tryptophan (Trp) catabolism in patients with newly diagnosed diffuse large B-cell lymphoma (DLBCL) and primary mediastinal large B-cell lymphoma (PMBCL).
Methods: A total of 133 DLBCL and 5 PMBCL patients who received at least 1 cycles of rituximab-CHOP like regimen were enrolled. Baseline serum Trp and Kyn levels in 138 lymphoma patients and 50 healthy volunteers were measured using an ultra-performance liquid chromatography–tandem mass spectrometry system, and associations with various clinical parameters analyzed. IDO expression was histologically evaluated within affected tumor sites of 103 patients.
Results: Enrolled patients comprised 77 males and 61 females (age range 24-90, median 69 years), with estimated overall survival (OS) at 5 years of 74.0%. The serum Kyn concentration was significantly higher in the patients than in the healthy volunteers (median: 1.63 μM, 1.09 μM, respectively, *P*<0.001). The serum Trp concentration was significantly lower in the patients than in the healthy volunteers (median: 50.9 μM, 63.4 μM, respectively, *P*<0.001). Therefore, the serum Kyn/Trp ratio was significantly higher in the patients than in the healthy volunteers (median: 31.2, 16.5, respectively, *P*<0.001). Patients were divided into two groups according to their serum Kyn/Trp ratio (Kyn [μmol/L)/Trp [μmol/L] x10^3) since high IDO activity results in increased Kyn and decreased Trp concentrations, meaning a high serum Kyn/Trp ratio. Of four factors determining the international prognostic index for DLBCL, a high serum Kyn/Trp ratio (>27.5) was significantly associated with advanced Ann Arbor stage (III-IV), high LDH (>upper normal limit), high age (≥61), poor performance status (2-4), but was not associated with extranodal sites (>1). Interestingly, hypoalbuminemia (Alb<4) was also significantly associated with high serum Kyn/Trp ratio. OS was significantly shorter in patients with a high serum Kyn/Trp ratio compared to those with a low ratio (OS rate at 5 years, 62.8 *vs* 92.7%, *P*=0.0025; **Figure**), however, high serum Kyn/Trp ratio was not an independent risk factor for OS in multivariate analysis. In immunostaining analyses, lymphoma cells were negative, but macrophages and dendritic cells in the microenvironment were positive for IDO. No significant correlation existed between the serum Kyn/Trp ratio and the degree of histologically IDO positive cells in the tumor microenvironment. There were no significant differences in OS according to the degree of histologically IDO positive cells in the tumor microenvironment.

Figure: Overall survival of DLBCL patients according to the serum Kyn/Trp ratio

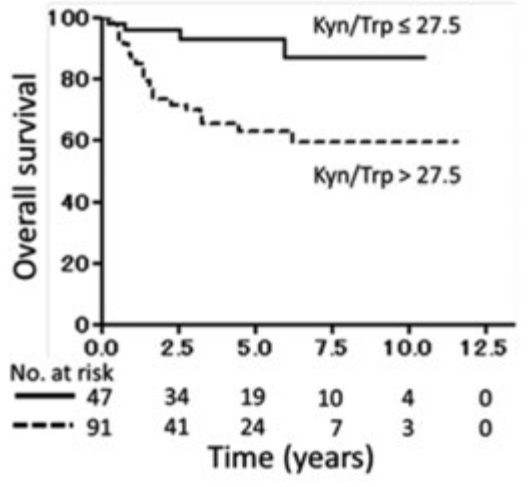

Figure 1.

Summary/Conclusion: Baseline high serum Kyn/Trp ratio was associated with poor prognosis in DLBCL patients, however the immunohistological evaluation of IDO expression in the tumor sites was associated with neither serum Kyn/Trp ratio nor prognosis. Furthermore, high serum Kyn/Trp ratio was significantly associated with known poor prognostic factors of DLBCL. Wherefore, novel treatment strategy targeting IDO is attractive for DLBCL patients with high serum Kyn/Trp ratio.

EARLY MORTALITY IN PATIENTS WITH NEWLY DIAGNOSED PRIMARY CNS LYMPHOMA

C.-J. Liu[1,*], C.-H. Lin[2], Y.-C. Liu[1], C.-J. Teng[3], C.-M. Yeh[1], Y.-C. Hong[4], Y.-B. Yu[3], P.-S. Ko[1], L.-T. Hsiao[1], T.-J. Chiou[5], J.-H. Liu[1], J.-P. Gau[1], H.-Y. Wang[1]

[1]Division of Hematology, [2]Department of Medical Education, Taipei Veterans General Hospital, Taipei, [3]Division of Oncology and Hematology, Far Eastern Memorial Hospital, New Taipei, [4]Division of Hematology and Oncology, Kaohsiung Taipei Veterans General Hospital, Kaohsiung, [5]Division of Transfusion Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China

Background: Primary central nervous system lymphoma (PCNSL) is a relatively rare non Hodgkin lymphoma (NHL) and counts for approximate 3% of all CNS neoplasms. Despite advances in treatment, patients still encounter early mortality. The previous reports focused on long-term outcomes (Abrey LE *et al*., *J Clin Oncol*, 2006; Ferreri AJ *et al*., *J Clin Oncol*, 2003), in which the risk factors included age, performance status, CSF protein level, involvement of deep brain, serum lactate dehydrogenase, and intraocular involvement.
Aims: In this study, we would like to investigate the risk factors of early mortality in patients with PCNSL.
Methods: We enrolled newly diagnosed PCNSL patients at Taipei Veterans General Hospital, a national medical center in Taiwan, between January 1, 2002 and October 31, 2017. Patients without histopathological confirmations, those diagnosed with secondary CNS lymphoma, or those with AIDS were excluded. The cohort was followed up until the end of February 2018. The risk factors for mortality within 180 days were identified using univariate and multivariate Cox proportional hazards models. The factors with $p<0.1$ in the univariate analysis were included in the multivariate analysis. All treatments were estimated with the use of time-dependent covariates to prevent immortal time bias.
Results: The study cohort consisted of 129 PCNSL patients, with a median follow-up of 8.4 years. The median age of the patients was 64 years and 73 (56.6%) of them were male. The probability of early mortality (≤180 days) was 13.4% (95% confidence interval [CI] 8.4–20.9%). In the univariate analysis, age ≥80 (hazards ratio [HR] 4.19), involvement of basal ganglia (HR 4.56) and ECOG performance status ≥2 (HR 2.93), hemoglobin<11 g/dl (HR 2.69), platelets<150,000/ml (HR 2.53), albumin ≥3.9 g/dl (HR 0.23), receiving steroid (HR 0.40), methotrexate (HR 0.33), and immunotherapy with rituximab (HR 0.28) were associated with early mortality. Age ≥80 (adjusted HR 5.08, 95% CI 1.21–21.25, p=0.026), involvement of basal ganglia (adjusted HR 7.46, 95% CI 2.08–26.78, p=0.002), and receiving steroid (adjusted HR 0.18, 95% CI 0.04–0.88, p=0.034) were identified as independent predictors for early mortality in the multivariate analysis.

Table 1.

Table Risk factors for early mortality in patients with Primary CNS Lymphoma

	Univariate analysis		Multivariate analysis[a]	
Predictive variables	**HR (95% CI)**	***P* value**	**HR (95% CI)**	***P* value**
Age ≥ 80	4.19 (1.45–12.09)	0.008	5.08 (1.21–21.25)	0.026
Sex (male)	0.82 (0.31–2.18)	0.688		
Site				
Frontal lobe	0.55 (0.18–1.70)	0.297		
Parietal lobe	0.56 (0.16–1.97)	0.367		
Temporal lobe	1.04 (0.38–2.87)	0.938		
Occipital lobe	1.56 (0.50–4.83)	0.443		
Basal ganglia	4.56 (1.58–13.14)	0.005	7.46 (2.08–26.78)	0.002
Brain stem	0.58 (0.08–4.38)	0.596		
Cerebellum	1.10 (0.25–4.82)	0.904		
ECOG ≥ 2	2.93 (0.95–9.08)	0.063	0.78 (0.21–2.89)	0.704
Hemoglobin < 11 g/dl	2.69 (0.98–7.40)	0.056	3.92 (0.96–15.93)	0.056
Platelets < 150,000/μl	2.53 (0.92–6.95)	0.073	2.29 (0.71–7.36)	0.165
Albumin ≥ 3.0 g/dl	0.23 (0.08–0.66)	0.007	0.43 (0.12–1.58)	0.205
Lactate dehydrogenase ≥ 250 U/L	1.34 (0.49–3.69)	0.574		
CSF protein ≥ 100 mg/dl	1.05 (0.11–10.13)	0.964		
Treatment[b]				
Steroid	0.40 (0.14–1.14)	0.087	0.18 (0.04–0.88)	0.034
Methotrexate	0.33 (0.12–0.90)	0.030	0.54 (0.13–2.20)	0.386
Rituximab	0.28 (0.09–0.88)	0.030	0.40 (0.08–1.96)	0.260

HR, hazard ratio; CI, confidence interval; ECOG, Eastern Cooperative Oncology Group performance
[a]All factors with $p < 0.1$ in the univariate analysis were included in the Cox multivariate analysis.
[b]Tuberculosis was analyzed as a time-dependent covariate in the Cox regression model.

Summary/Conclusion: We identified age ≥80 and involvement of basal ganglia as independent risk factors for early mortality in the patients with PCNSL. Of note, steroid treatment could prevent the patients from the early death. Identifying patients with risks of early mortality may help clinicians initiate appropriate management and early treatment. Further validation of our findings in other cohorts is warranted.

PB1759

DESCRIPTION AND ANALYSIS OF 36 CENTRAL NERVOUS SYSTEM RELAPSE IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA WITHIN LYSA STUDIES

S. Bernard[1,*], L. Oberic[2], J. Lazarovici[3], A. Perrot[4], K. Van Eygen[5], C. Sarkozy[6], C. Sebban[7], E. Van Den Neste[8], O. Fitoussi[9], B. Slama[10], Y. Arkam[11], C. Thieblemont[1]

[1]Hemato-oncology, Hôpital Saint Louis-APHP, PARIS, [2]Hematology, IUCT Oncopole, Toulouse, [3]Hematology, Institut Gustave Roussy IGR, Villejuif, [4]Hematology, CHU Brabois, Vandoeuvre les Nancy, France, [5]Hematology, Kortrijk, Kortrijk, Belgium, [6]Hematology, CHU Lyon Sud Pierre Benite, [7]Hematology, Centre Leon Berard, Lyon, France, [8]hematology, UCL, Louvains Saint Luc, Belgium, [9]Hematology, Polyclinique Bordeaux Nord, Bordeaux, [10]CH Avignon, Avignon, [11]hematology, CH Emile Muller, Mulhouse, France

Background: Central nervous system (CNS) relapse in patients with diffuse large B-cell lymphoma (DLBCL) is an uncommon event (2-5%) associated with a very poor prognosis. We present a descriptive analysis of characteristics and outcome of 36 patients who presented CNS relapse following their 1st line of treatment for a DLBCL treated prospectively in 7 LYSA Phase III trials (LNH03 / LNH07)/LNH09).
Aims: CNS relapse in the rituximab era is a rare event but with still a poor prognois. We proposed in this study to collect datas of patients with a CNS relapse and treated with RCHOP regimen to analyse pertinent clinical findings to improve diagnosis and therapeutic options in this population.
Methods: We reviewed the records of 1885 patients with *de novo* DLBCL and included in 7 phase III LYSA studies between 2003 and 2009. 1615 patients younger than 80 were treated with CHOP +/- Rituximab and ACVBP +/- Rituximab, and 270 older than 80 were treated with mini-CHOP-Rituximab. All patients with a documented CNS relapses (CSF analysis, MRI, CT-Scan) were collected and analysed.
Results: Median age of patients with CNS relapse was 71 (20-89).28 patients were under 80 years of age and were treated for 4 patients with R-ACVBP, and for 24 patients with RCHOP21/14. 8 patients were older than 80 years and were treated with RminiCHOP. At the initial diagnosis, 2 patients had a low risk CNS-IPI score (0-1), 15 an intermediate risk (2-3) and 17 patients presented a high risk (4-6) (2 unassessed patients). The

median time to relapse was 247.5 days (93-781). At CNS relapse, 18 patients (50%) had parenchymal involvement, 16 had meningeal involvement (44%), 6 had epidural disease (17%), 1 had ocular involvement (2.8%), and 7 had two associated CNS lesions (19%). Treatment of this CNS relapse included methotrexate and / or aracytin high dose-based chemotherapy in 20 cases (56%) with 3 intensifications (8.3%), local treatment in 20 cases [intrathecal chemotherapy in 12 cases (33%); radiotherapy in 8 cases (22%)], and palliative treatment in 10 cases (28%). The median survival after CNS relapse was 86 days (2-3172), or 2.9 months. 2 patients (5.4%) had a survival greater than 2 years; in both cases patients had benefited of an autologous stem cell tranplantation (ASCT).

Summary/Conclusion: We confirm the poor prognosis of CNS relapses in DLBCL patients, as well as their early onset. An optimization of CNS relapses prophylaxis is essential in agressive lymphoma. The therapeutic management of CNS relapses is disparate and non-consensual, requiring the establishment of multicenter relapse therapy protocols adapted to these rare events.

PB1760

OXALIPLATIN-BASED REGIMEN AS SALVAGE AND STEM-CELL MOBILIZING THERAPY IN RELAPSED REFRACTORY LYMPHOMAS

L. Manconi*, E. Coviello, F. Guolo, L. Giannoni, P. Minetto, F. Canale, M. Gambella, F. Ballerini, R.M. Lemoli, M. Gobbi

Clinic of Hematology, Department of Internal Medicine (DiMI), University of Genoa, Policlinico San Martino, IRCCS per l'Oncologia, Genoa, Italy

Background: Cisplatin containing regimens showed promising results as salvage chemotherapy (CT) in relapsed or refractory (R/R) lymphomas, mainly as bridge to autologous stem cells transplant (ASCT). Tolerability is mainly impaired by mucositis and cisplatin-associated renal and neurological toxicity. Oxaliplatin shows a better toxicity profile, but at the present time few data are available in R/R lymphomas setting.

Aims: To investigate the feasibility and efficacy of oxaliplatin, cytarabine and dexamethasone (DHAOx) as salvage and mobilizing regimen for peripheral blood stem cells (PBSC).

Methods: We retrospectively analyzed 83 R/R lymphoma patients diagnosed between October 2004 and October 2014, who received DHAOx as salvage CT. Forty-one had Diffuse Large B-cell Lymphoma (DLBCL, 49%), 10 Hodgkin Lymphoma (HL, 12%), 13 Mantle Cell Lymphoma (15%), 15 other Indolent Lymphomas (18%) and 4 Peripheral T-cell Lymphoma (5%). Median age was 59 (range 22-79). DHAOx schedule consists inq21 days-administration of dexamethasone 40 mg/die on days 1-4, oxaliplatin 130 mg/m^2 on day 1, cytarabine 2 g/m^2 bid on day 2.In B-cells lymphomas, Rituximab 375 mg/m^{2}was added on day 2. G-CSF was administered from day 7 until absolute neutrophil count recovery or from day 5 to 10 (5 mcg/Kg/die) if PBSC collection was scheduled. We analyzed overall response rate(ORR), progression free survival (PFS), hematological and non-hematological toxicities and success rate of BPSC collection.

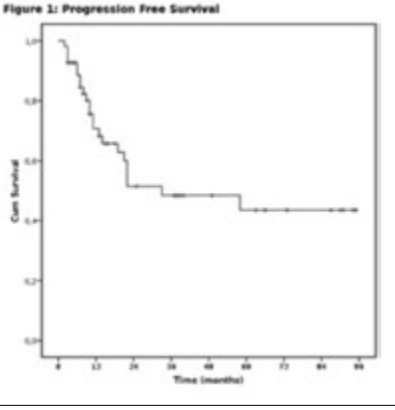

Figure 1.

Results: ORR was 64%, Complete remission (CR) was achieved in 48 patients (55%), partial remission (PR) in 8 patients (9%), 32 patients did not respond (36%). Patients affected by DLBCL had significantly higher probability of achieving CR if compared to HL, MCL and indolent lymphomas ($p<0.05$). Median PFS was 33 months (fig.1). The projected OS at 36 months was 54.5%.%. Survival was better in patients with DLBCL and HL ($p<0.05$). Grade >2 non hematological toxicity was observed in 27 patients (33%),most frequently oral mucositis and diarrhea (6 cases, 8%), FUO (17 cases, 21%), sepsis (3 cases, 4%), paresthesia (5 patients, 6%). No patients experienced acute renal impairment. Among DLBCL patients, 81% were treated in second line,19% in third or subsequent line. ORR was 71%. CR was obtained in 60%, PR in 11%. Eleven patients did not respond 29%. The median PFS was not reached and the projected OS at 36 months was 45.5. Following DHAOx and G-CSF priming, stem cell harvest for ASCT was planned in 40 patients (48%), all of them successfully performed the procedure and reached the target of 4x10^6 CD34+/Kg. Only 1 heavily pretreated patient needed plerixafor administration. All patients performing stem cell collection were able to proceed to ASCT.

Summary/Conclusion: Our experience shows that the use of oxaliplatin instead of cisplatin is feasible, alongside showing similar efficacy compared to conventional cisplatin containing regimens for R/R lymphomas. Low hematological and non-hematological toxicity as well as good capability of PBSC mobilization were observed. Notably, no renal toxicity was observed. The very good toxicity profile allowed all eligible responding patients to proceed with planned ASCT consolidation. Oxaliplatin-high dose cytarabine salvage therapy is therefore a reasonable option, expecially for R/R DLBCL patients considered eligible for ASCT.

SECOND TUMORS IN PATIENTS WITH B-CELL NON-HODGKIN'S LYMPHOMAS (BNHL): WITH HEPATITIS C(HCV) AND WITHOUT HEPATITIS C

S. Lepkov[1,*], I. Subortceva[2], J. Ribuchina[3], G. Tumian[4], O. Kolomeitsev[4], N. Kokosadze[4], P. Zeynalova[4], I. Komarov[4], S. Borisovckay[5], N. Kuprishina[4], O. Zaharov[6], R. Ivashenko[7], Y. Kemih[7], I. Lazarev[6], O. Ettinger[1], I. Nikitin[1]

[1]therapy, National Research Medical University named by N.I. Pirogov, [2]haematology, National Medical Research Center for Hematology, [3]oncology, [1] N.N. Blokhin National Cancer Research Center, Moscow,, [4]oncology, N.N. Blokhin National Cancer Research Center, Moscow,, [5]therapy, City Clinical Hospital. V.M. Buyanova, [6]haematology, Hematologic Moscow City Center at the State Clinical Hospital named by S. Botkin, [7]radiology, City Clinical Hospital. V.M. Buyanova, moscow, Russian Federation

Background: Information about the second tumors that arise after recovery from BNHL is not so extensive. Information about the second tumor after BNHL with HCV is scarce.

Aims: The purpose of our study was to study which secondary tumors, with what frequency and at what time develop in these groups of patients. The study included patients with BNHL treated from 2001 to 2017.The first group was patients with BNHL+HCV, there were 213. In the second group was patients with BNHL without HCV there were 835. The median age was in the first group-48 years, in the second group-60 years. The ratio of men and women in the first group was 1: 1, in the second 1: 2.5

Methods: During the observation in the first group, the second tumors developed in 23 patients (11%), in the second group-in 18 patients (2%). In the first group of the onset of the second tumor ranged from 16 to 96 months, the median was 44 months after the end of treatment BNHL. In the second group, the second tumor occurred from 47 to 144 months, the median was 60 months.

Results: During the observation in the first group, the second tumors developed in 23 patients (11%), in the second group-in 18 patients (2%). In the first group of the onset of the second tumor ranged from 16 to 96 months, the median was 44 months after the end of treatment BNHL. In the second group, the second tumor occurred from 47 to 144 months, the median was 60 months. In the first group, 5 of 23 patients developed MDS / AML. Another 17 patients developed solid tumors. Among the solid tumors were 3 primary liver cancer, 5 renal cancer, 5 colon cancer. According to one type of cancer, the following occurred: uterine body cancer, brain tumor, soft tissue sarcoma, lung cancer, breast cancer. In all patients during the diagnosis of lymphoma, the viral load was high. The median viral load was 2.7x10^6 copies / ml. The genotype of hepatitis C was determined in 18 of 23 patients. The genotype 1b was in 14 of 18 patients, 2 genotype in 2 patients, and the 3 genotype was in 2 patients. Of the 23 cases, the second tumors were diagnosed in 18 patients who did not receive antiviral therapy and only 5 patients who received antiviral therapy with interferon + ribavirin. All patients who developed MDS / AML received only polychemotherapy. In the first group with IHC, the study of the expression of HCV proteins was carried out in 13 cases. Expression of HCV proteins was detected in 6 cases: liver cancer-3, kidney cancer-3. In the second group of patients, of the 18 second tumors were breast cancer-3 patients, uterine body cancer-4 patients, thyroid cancer was in 2 patients. In one case: stomach cancer, colon cancer, prostate cancer, melanoma, kidney cancer, laryngeal cancer, hepatocellular cancer, lung cancer, skin cancer were identified.

Summary/Conclusion: When comparing these two groups of patients with BNHL + HCV and BNHL without HCV, the frequency of diagnosis of the second tumor was higher than in the BNHL group-11% *versus* 2%. The first group of patients was younger, the second tumors occurred earlier than 44 months compared to 60 months. In patients receiving antiviral therapy, the second tumor was diagnosed reliably less frequently than in a group of patients who did not receive antiviral therapy. HCV is an additional risk factor for developing second tumors.

PB1762

CLINICAL VALUE OF ABNORMAL FINDINGS ON BRAIN MAGNETIC RESONANCE IMAGING IN PATIENTS WITH INTRAVASCULAR LARGE B-CELL LYMPHOMA

Y. Abe*, K. Narita, H. Kobayashi, A. Kitadate, M. Takeuchi, K. Matsue

Hematology/Oncology, Kameda Medical Center, Kamogawa, Japan

Background: Neurological symptoms related to the involvement of the central nervous system have been commonly seen at diagnosis and at relapse in intravascular large B-cell lymphoma (IVLBCL). Although various patterns of abnormal findings on brain magnetic resonance imaging (MRI) in patients with IVLBCL have been reported, most of them were from case reports or small case series in selected patients.
Aims: We aimed to investigate the clinical value of abnormal findings detected by brain MRI in patients with IVLBCL with regard to diagnosis and prognosis.
Methods: Thirty-three consecutive patients pathologically diagnosed and treated at Kameda Medical Center between 1998 and 2017 were identified. The baseline clinical characteristics, treatments, and outcomes of these 33 patients had been retrospectively reviewed. Brain MRI was performed as previously reported, and the abnormalities were classified into the following four patterns by two neuroradiologists (Figure): (1) hyperintense lesion in the pons on T2-weighted imaging (T2WI), (2) nonspecific white matter lesions, (3) infarct-like lesions, and (4) meningeal thickening and/or enhancement.

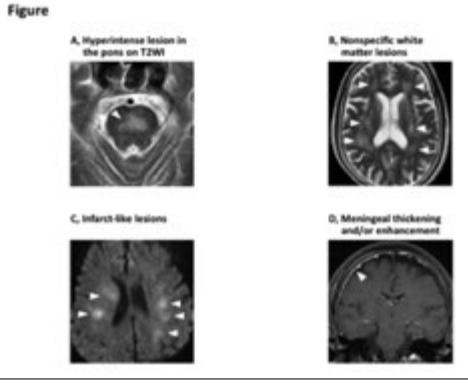

Figure 1.

Results: We identified 18 patients with NL with a total of 53 involved peripheral nerves (PN) diagnosed and treated at our institution who were evaluated with both pretreatment contrast-enhanced MRI and PET-CT. Among the 18 patients with NL, contrast-enhanced MRI described abnormal findings on PN in 17 (94.4%) patients, while PET-CT described them in 12 (66.7%) patients, although the difference was slightly insignificant (P=0.074). Among the 53 involved PN, 52 (98.1%) were positive for contrast-enhanced MRI, while only 21 (39.6%) were positive for PET-CT (P<0.001). Detection sensitivities of PET-CT for cauda equine (11.1%) and lumbosacral nerves (31.0%) were lower compared to contrast-enhanced MRI, whereas PET-CT detected abnormal findings on cranial nerves with as high detection sensitivity (81.8%) as contrast-enhanced MRI. Patients who were negative for PET-CT included more patients with systemic presentation of lymphoma compared to those who were positive for PET-CT, although the difference was not statistically significant (50.0% *vs* 33.3%, respectively; P=0.627), and soluble interleukin-2 receptor in patients with NL negative for PET-CT was significantly higher than those positive for PET-CT (P=0.049). Patients negative for PET-CT had relatively favorable overall survival than those positive for PET-CT (median, 37.2 *vs* 7.5 months, respectively; P=0.234). All abnormal findings on PN described by contrast-enhanced MRI and PET-CT in patients who responded to therapy and had follow-up imaging studies showed significant improvement, suggesting that these findings were the manifestations of neural involvement of NL.

Summary/Conclusion: Our findings revealed that most patients with IVLBCL presented abnormal findings on pretreatment brain MRI even if they had no neurological symptom. In particular, hyperintense lesion in the pons on T2WI was frequently observed in patients with IVLBCL irrespective of presence or absence of impaired consciousness, suggesting that this pattern may be pathognomonic and valuable for timely diagnosis of IVLBCL. Improvement in all types of abnormal findings on follow-up brain MRI indicated that all these findings might reflect structural changes associated with IVLBCL and might be useful for confirmation of the therapeutic effect.

PB1763

NEW TRICKS FOR OLD DRUGS: COMBINATION OF ALBUMIN-BOUND PACLITAXEL AND PEGYLATED LIPOSOMAL DOXORUBICIN IN THE TREATMENT OF RELAPSED/REFRACTORY DIFFUSE LARGE B CELL LYMPHOMA

L. Wang[1,*], Z.-J. Xia[2], X.-Q. Chen[2], W.-D. Wang[2]

[1]Hematology, ZhuJiang Hospital, Southern Medical University, [2]Sun Yat-sen University Cancer Center, Guangzhou, China

Background: There is great unmet need in improving the prognosis of patients with relapsed/refractory diffuse large B cell lymphoma (DLBCL).
Aims: How to get those patients into remission and enable them to receive autologous stem cell transplantation (ASCT) is a great challenge.
Methods: A phase 2 clinical trial was conducted to evaluate the efficacy and safety of rituximab in combination with **two nanoparticle-delivered chemotherapy drugs, albumin-bound paclitaxel and pegylated liposomal doxorubicin** (RAD) in patients with relapsed/refractory DLBCL who received at least two prior lines of immunochemotherapy.
Results: 13 patients were enrolled with a median age of 40 years. All patients received a median of 3 prior lines of therapy. 12 patients received at least two cycles of RAD. After 2 cycles of RAD, the complete response rate was 38.5%, partial response rate was 46.2%, and overall response rate was 84.6%. Three patients successfully received subsequent ASCT, and were still alive without disease after a follow-up time of 4 months, 15 months, and 29 months, respectively. Three patients died of disease progression when waiting for ASCT, and another three patients failed collection of stem cells due to bone marrow dysfunction. This RAD regimen was well tolerated with mostly reported adverse events being grade 2 or 3 hematologic events.

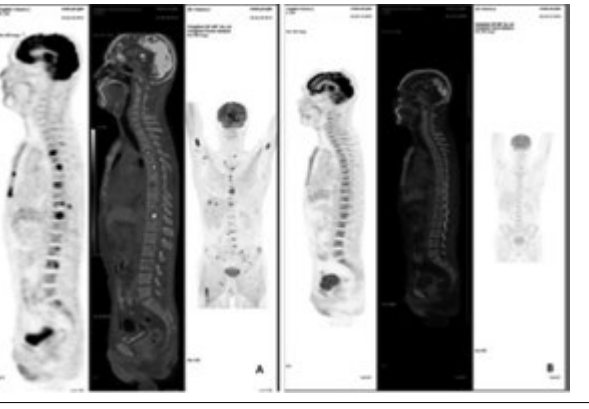

Figure 1.

Summary/Conclusion: In conclusion, we demonstrated that rituximab in combination with albumin-bound paclitaxel and pegylated liposomal doxorubicin was highly active in patients with relapsed/refractory DLBCL, and this regimen should be considered as an effective salvage therapy to bridge subsequent ASCT.

PB1764

"REAL WORLD" PRESENTATIONS OF DIFFUSE LARGE B CELL LYMPHOMA: A RETROSPECTIVE AUDIT OF HISTOPATHOLOGICAL & CLINICAL DIVERSITY, & EARLY MORTALITY

A. Thavarajah[1,*], W. Chinnery[2], L. Thomas[3], U. Igbokwe[4], P. Greaves[3]

[1]Barts and the London School of Medicine and Dentistry, Queen Mary University of London, [2]Department of Cancer & Clinical Support Services, [3]Department of Haematology, [4]Department of Histopathology, Barking Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom

Background: Diffuse large B cell lymphoma (DLBCL) is diagnosed in 3-5/100,000 people annually, with RCHOP (Rituximab, Cyclophosphamide, Hydroxydaunorubicin, Oncovin, and Prednisolone) chemotherapy remaining the standard & central nervous system (CNS) prophylaxis delivered based on an International Prognostic Index (IPI) of 4/5, or having a high risk anatomical site. Extended molecular histopathology with Ki67 proliferative index, cell of origin immunohistochemistry (COO-IHC: germinal centre/GCB or activated B cell/ABC), MYC expression, & genetic rearrangements are now routinely undertaken to evaluate prognosis. Local audit of practice is essential to capture histopathological diversity, early response, & mortality rates to ensure that we can adapt and provide the best care possible.
Aims: This retrospective audit scrutinises diagnostics, initial therapy, & mortality of DLBCL treated at a busy general hospital serving 800,000 people in a socio-economically challenged area of London, UK.
Methods: 100 patients diagnosed in 2016 & 2017 were retrospectively assessed using electronic health records. The Swedish Lymphoma Registry (SLR) was chosen as a comparator dataset.
Results: To obtain a snapshot of diagnostics and initial care, median follow-up was short (150 days). Median age was 72 years (27-90, where 33% of patients were over 80). 65% presented with stage 3/4 disease (comparable with SLR). IPI was 4 or 5 in 43% of patients (16% in SLR). 60% of patients were initiated on RCHOP chemotherapy and 20% on RCVP or R-GemCVP due to comorbidities. 2 received RCODOX-M due to high risk features. 15% received only palliative steroids or radiotherapy. CNS prophylaxis criteria were met in 50% of cases: 90% due to high IPI; 10% due to anatomical site. Prophylaxis was only administered in 15% of these cases (IT methotrexate alone in 50% & systemic methotrexate in 50%). Omissions were due to patients being unfit for treatment. 4 CNS relapses occured with 2 deemed high risk at diagnosis. Of the 85% of biopsies reporting Ki-67, 60% had a Ki-67>90% (10-30% reported elsewhere). COO-IHC was ABC in 41% of cases, GCB in 30%, & unclassifiable in 35% (comparable to literature). Of the 90% of cases reporting MYC, 44% showed overexpression where 85% were double or triple expresser with BCL2/6. Rearrangement of MYC/BCL2/BCL6 genes were assessed by FISH in only 45% of cases (45% omitted due to low IHC MYC expression, 30% due to inadequate biopsy material). In the 37 cases assessed, 5% showed only MYC rearrangement & 15% had a double or triple hit, greater than the rates of 5-10% reported elsewhere. Around 80% of patients under 60 years of age(yoa), 70% of patients 60-70yoa, & 60% of patients 70-80yoa survive 2 years, comparable to the SLR. 23 patients died within 100 days of diagnosis of whom 13 were over 80yoa & 3 under 60yoa. 62% of patients diagnosed over 80yoa died within 100 days; 50% of these deaths occurred in palliative patients & 50% received chemotherapy.

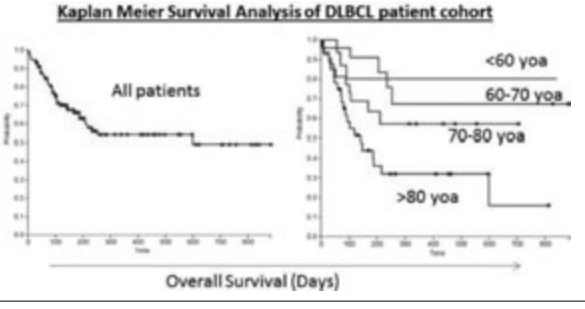

Figure 1.

Summary/Conclusion: This audit has revealed survival rates largely comparable to the registry data, but with high early death rates requiring scrutiny. High IPI scores account for a greater proportion than expected (43% *vs* 16% in the SLR). This may reflect late presentation of disease, or more molecular adverse features, with Ki67>90% & 'double-hit' disease apparently over-represented in this cohort. We emphasise that audit of 'real-world' practice is essential to elicit trends & regional differences, ensure equitable high quality care & delivery, enabling tailored service provision to its population.

PB1765

LIMITED IMPACT OF MYC, BCL2 AND BCL6 BREAKS IN THERAPEUTIC DECISIONS FOR DIFFUSE LARGE B CELL LYMPHOMAS (DLBCL) IN A REAL WORLD SETTING-A SINGLE CENTER EXPERIENCE

F. Rigotti[1], M. Gomes da Silva[2,*], S. Esteves[3], J. Cabeçadas[4]

[1]Facoltà di Medicina e Chirurgia, Università di Bologna, Bologna, Italy, [2]Hematology, [3]Clinical Trial Office, [4]Pathology, Instituto Portugues de Oncologia de Lisboa, Lisboa, Portugal

Background: Diagnosis of lymphomas with DLBCL morphology and *MYC, BCL2* and/or *BCL6* breaks (double hit, DH) is rare but relevant given the poor outcome with conventional treatment and possible treatment-escalation benefits suggested by retrospective studies.
Aims: To characterize the impact of *MYC*, *BCL2* and *BCL6* breaks in treatment decisions in DLBCL patients (pts) enriched for immunophenotypically defined germinal center type (GC) and to evaluate the relationship between breaks and MYC and BCL2 expression in a single center.
Methods: All DLBCL biopsies tested by Fluorescence *in situ* hybridization (FISH) for *MYC*, *BCL2* and *BCL6* breaks between 2010-2017 were reviewed. Cell of origin was defined according to Hans algorithm. Positivity cut-offs for MYC and BCL2 were ≥40% and ≥50%, respectively. FISH was mostly done in pre-selected GC cases and in additional pts with unusual morphological and/or clinical features. Pts characteristics and outcomes were reviewed and groups compared by Fisher exact test. The impact of FISH on clinical decisions was assessed as the number of pts needed to screen (NNS) in order to intensify treatment in one, calculated in two scenarios using the prevalence of DH and the number of treatment changes informed by FISH. The NNS to avoid one progression/death was calculated based on published data in DH pts comparing PFS with aggressive treatments *versus* RCHOP according to Altman *et al.* (B Med J 1999)
Results: 76 biopsies (73 diagnosis, 3 relapse) (9% of all DLBCL) underwent FISH; the proportion of pts analyzed increased over time, the majority (58%) after the publication of the revised WHO classification draft. The population (49% male, median age 57, 66% stage III/IV, 39% intermediate-high and high-risk IPI) included 43% pts older than 60 years, 16% transformed lymphomas and 30% pts with significant co-morbidities, including 9 previously exposed to anthracyclines. 85% were GC and 16% were double MYC/BCL2 expressors (DE). 16% (95%CI 8%>26%) had DH (*6 MYC/BCL2*, *5 MYC/BCL6* and 1 *MYC/BCL2/BCL6),* more frequently in the DE group (45% *versus* 9% in non-DE, p=0.01). 75% pts received RCHOP and 12% had aggressive regimens (mostly LMB96) based on clinical risk factors, age, fitness and FISH. Out of 12 DH cases 3 had aggressive regimens, only in one due to the FISH result; reasons for not escalating treatment in others included age, comorbidities and prior anthracyclines. Only 35/76 pts were fit for aggressive regimens; of those 3 were DH (9%, 95%CI 2-23%) and treatment was escalated in 2. Assuming a 9% prevalence of DH in fit pts and that 2/3 would change treatment based on FISH, the NNS for one therapeutic change would decrease from 76 to 17. For a median 8-month PFS with RCHOP (Petrich *et al*., Blood 2014), a 47% reduction of PFS events with aggressive regimens (HR=0.53; 95% CI 0.29-0.98) (Howlett *et al*., Br J Haematol 2015), a 16% prevalence of DH and 8% therapeutic changes, 469 pts (95% CI 313-11250) would need testing to avoid one progression/death at 8 months. If selection criteria for FISH included only fit pts, this would decrease to 102 (95% CI 68-2425).
Summary/Conclusion: This retrospective single center study suggests that from the therapeutic perspective DLBCL candidates for FISH can be restricted considering clinical information added to cell-of-origin and/or protein expression. This impacts on costs and feasibility of large scale testing while new targeted therapies with acceptable toxicity profiles for a predominantly elderly/co-morbid population are unavailable.

PB1766

R-VACOP-B+RT *versus* DOSE-ADJUSTED R-EPOCH IN FRONTLINE MANAGEMENT OF PRIMARY MEDIASTINAL B-CELL LYMPHOMA: SIMILAR EFFICACY WITH DIFFERENT TOXICITY PROFILE

E. Scomazzon[1,*], S. Imbergamo[1], A. Visentin[1], M. Riva[1], F. Lessi[1], A. Branca[1], T. Berno[1], G. Scapinello[1], M. Laurino[1], S. Pravato[1], S. Vio[2], M. Gregianin[3], C. Boso[4], F. Adami[1], G. Binotto[1], R. Zambello[1], G. Semenzato[1], F. Vianello[1], F. Piazza[1], C. Gurrieri[1], L. Trentin[1]

[1]Haematology and Clinical Immunology Unit, University of Padua, [2]Radiology Unit, University of Padua, Padua, [3]Nuclear Medicine Unit, S.Giacomo Hospital, Castelfranco Veneto, [4]Radiotherapy and Nuclear Medicine Unit, IOV-IRCCS, Padua, Italy

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is a subtype of aggressive B-cell non-Hodgkin lymphoma, with a usual presentation being a bulky anterior mediastinal mass. It affects predominantly females in their third-fourth decade of life, who present signs and symptoms related to the mediastinal mass. Historically, R-CHOP (Rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone) has been the standard treatment for PMBCL, in combination with consolidative radiotherapy. An Italian retrospective study (Zinzani PL *et al.* 2009) showed that regimens R-

MACOP(Rituximab/methotrexate/leukovorin/cyclophosphamide/doxorubicin/vincristine/prednisone/bleomycin)/R-VACOP-B (Rituximab, etoposide, doxorubicin, cyclophosphamide, vincristine, prednisone, bleomycin) with radiotherapy is an effective therapy for the treatment of PMBCL; recently, a comparison study demonstrates a superiority of Dose Adjust (DA)-R-EPOCH (rituximab, etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin) towards R-CHOP. In literature there are no comparison study between DA-R-EPOCH and R-VACOP-B.
Aims: The aim of this study was to compare the long-term efficacy and the most relevant side effects of the R-VACOP-B and DA-R-EPOCH regimens in PMBCL patients from a single institution.
Methods: We conducted a retrospective study on 49 patients (30 females, 19 males) affected by PMBCL, based on WHO criteria 2008, referred to the Hematology Division of Padua University Hospital. Median age at the diagnosis was 33 years (18-58). Fifteen patients (30.6%) were treated with DA-R-EPOCH with a median of 6 cycles (6-8), 34 patients (69.3%) were treated with R-VACOP-B followed by consolidative radiotherapy (RT) (30 Gy in 17 fractions).
Results: During a median follow up of 63 months, 8 patients out of 49 relapsed and 4 died (3 for progression, 1 for heart attack). The estimated 5-year progression free survival (PFS) and OS for the whole population were 81.8% and 92.5%, respectively. In the R-VACOP-B group with a follow up of 95 months, we found a 5-years PFS of 82% and a OS of 97%, for the DA-R-EPOCH group the median follow-up is shorter (13 months) with a 1-year PFS and a OS of 89% and 84%, respectively. Regarding the serious adverse events, we found an increase of haematological toxicities in the DA-R-EPOCH group ($p<0.00001$) without a significant incidence of major infections. We found a similar rate of cardiological events between the two groups, but a higher pulmonary toxicity in the R-VACOP-B + RT group ($p<0.0006$).
Summary/Conclusion: With the limitations of a retrospective survey with a small number of patients, our data suggest that both regimens are equally effective for the treatment of PMBCL. Regarding the toxicities, DA-R-EPOCH causes more G3/G4 neutropenia than R-VACOP-B regimen, with no increase in major infections. Likewise, there is no difference in the cardiological toxicity between the two regimens probably due to the presence of a comparable cumulative dose of anthracyclines in both treatment schemes. On the contrary, Bleomycin and consolidative mediastinal radiotherapy in the R-VACOP-B regimen may account for the significant difference in pulmonary side-effect observed. In conclusion, our study provide evidence that both DA-R-EPOCH and R-VACOP-B regimens are very effective for the treatment of PMBCL, with response rates higher than those reported in the literature for R-CHOP+RT, DA-R-EPOCH showed a worse though manageable toxicity profile than R-VACOP-B + RT, however, in the latter regimen the role of consolidative RT is still controversial.

A PHASE IB, OPEN LABEL, MULTICENTER TRIAL OF PIXANTRONE, ETOPOSIDE, BENDAMUSTINE AND, IN CD20-POSITIVE TUMORS, RITUXIMAB (PREBEN) IN RELAPSED AGGRESSIVE LYMPHOMAS OF B- OR T-CELL PHENOTYPE

J. Jørgensen[1], S. Leppä[2], T. Relander[3], T.S. Larsen[4], G.F. Lauritzsen[5], P. Brown[6], S. Mannisto[2], G. Minotti[7], P. Menna[7], H. Holte[5], K. Liestol[8], H. Toldbod[1], F. Damore[1,*]

[1]Dept. of Hematology, Aarhus University Hospital, Aarhus, Denmark, [2]Dept. of Oncology, Helsinki University Hospital, Helsinki, Finland, [3]Dept. of Oncology, Skane University Hospital, Lund, Sweden, [4]Dept. of Hematology, Odense University Hospital, Odense, Denmark, [5]Dept. of Oncology, Oslo University Hospital, Oslo, Norway, [6]Dept. of Hematology, Copenhagen University Hospital, Copenhagen, Denmark, [7]Clinical Pharmacology Laboratory, University Hospital Campus Bio-Medico, Rome, Italy, [8]Dept. of Informatics, University of Oslo, Oslo, Norway

Background: Aggressive non Hodgkin lymphomas (aNHL) relapsing after high-dose therapy or, in not transplant-eligible patients (pts), after 1st line chemotherapy, represent an unmet clinical need. Therefore, we developed a salvage combination regimen based on pixantrone, an azaanthracenadione recently approved in Europe for pts with multiply relapsed or refractory aNHL, etoposide, bendamustine and, in CD20+ tumors, rituximab (PREBEN/PEBEN). A preliminary pre-trial experience on heavily pretreated aNHL pts showed good feasibility and efficacy and was previously reported. On this background, the Nordic Lymphoma Group launched an open label phase 1b/2 study (EudraCTno.201500075839) testing the feasibility and efficacy of the P[R]EBEN regimen in relapsed aNHL of B-or T-cell phenotype.
Aims: Here, we present the final results of the dose finding phase 1 part of the P[R]EBEN study.
Methods: According to predefined criteria, pts were subdivided in 'fit' and 'frail'. 'Fit' pts entered the phase 1 part of the study at baseline dose level. This consisted of 4 to 6 cycles of Pixantrone 50 mg/m2 i.v. day 1+8, Etoposide 100 mg i.v. day 1, Bendamustine 90 mg i.v. day 1 with or without the addition of Rituximab 375 mg/m2 i.v. day 1. 'Frail' pts entered directly the phase 2 part of the study at the same baseline dose level. Dose escalation was only applied to 'fit' pts and done according to a Bayesian model. Maximum tolerated dose (MTD) was based on the occurrence, within the first two cycles of therapy, of at least two DLT events (uncomplicated Grade 4 neutropenia lasting more than 5 days in patients without marrow involvement; grade 3-4 febrile neutropenia, or neutropenic infection; grade 4 thrombocytopenia; grade 3 drug-related non-hematopoietic toxicity with the exception of nausea, vomiting and alopecia). Primary end-points were identification of the MTD in phase 1 and overall response rate (ORR) in phase2. MTD was defined as the Response evaluation was performed by PET/CT after cycle 2 and at the end of therapy (EOT).
Results: In total, five pts were treated in the phase 1 part of the study. They had a median age of 60 years (range 39-68 years). Four of the pts (3 males and 1 female) had diffuse large cell B-cell lymphoma (DLBCL) and one (male) peripheral T-cell lymphoma (PTCL). All had relapsed disease after autologous transplant. The median time from last treatment to relapse was 20 months (range 8-86 months). All the chemotherapy courses were administered in an out-patient setting. No toxic deaths occurred. A total of 6 SAEs were reported among 4 pts: one grade 1 (transitory asymptomatic troponin T increase after cycle 3), one grade 2 (respiratory tract infection with non-neutropenic fever at cycle 6), three grade 3 (1 non-neutropenic fever at cycle 4, 1 neutropenic fever with anemia at cycle 4, 1 pneumonia/sinusitis at cycle 2), and one grade 4 (sepsis at cycle 3). All SAEs resolved without premature treatment interruption. No overt cardiac toxicity was recorded. Two DLT-defining events occurred within cycle 2 at baseline level, fulfilling MTD criteria. The two DLT defining events were: (i) neutropenic infection and (ii) post-therapeutic neutropenia (<0.5 mia/l) of >5 days in a pt without marrow involvement. PK measurements for pixantrone are ongoing. ORR was 60% after 2 cycles (1CR, 2 PRs) and at EOT (1 PR converted to CR: 2CR, 1PR).
Summary/Conclusion: The MTD of the PREBEN regimen was Pixantrone 50mg/m^2 i.v. day 1+8, Etoposide 100 mg i.v. day 1, Bendamustine 90 mg i.v. day 1 and Rituximab 375mg/m2 i.v. day 1. The schedule was feasible and the preliminary efficacy data are promising.

PB1768

A COMPREHENSIVE REVIEW OF PUBLISHED DATA ON THE TREATMENT OF RELAPSED/REFRACTORY (R/R) PERIPHERAL T-CELL LYMPHOMA (PTCL): AN EVIDENCE-BASED ASSESSMENT

E. Marchi[1,*], K. Tobinai[2], D. Maruyama[3], H. Nagai[4], O. O'Connor[1]

[1]Medicine, Columbia University Medical Center, New York, United States, [2]Geriatric Health Services Facility Rehabilitation Care Funabashi, Chiba, [3]Department of Hematology, National Cancer Center Hospital, Tokyo, [4]Department head of Hematology/Oncology Research, National Hospital Organization Nagoya Medical Center, Nagoya, Japan

Background: Peripheral T-cell lymphomas (PTCL) are a group of rare clinically aggressive heterogeneous diseases associated with a poor prognosis. Standard first-line chemotherapy achieves complete response (CR) rates ranging from 30% to 60% and long-term survival rates of only 15% to 25% at 5 years. Patients with relapsed/refractory (R/R) disease have an even worse prognosis with overall survival (OS) and progression-free survival (PFS) of 5.5 and 3.1 months, respectively. There is no consensus on the management of relapsed disease, primarily because the evidence supporting most treatment approaches is modest at best. Many approaches, deemed 'standard-of-care,' are often not well supported by the literature, and broad categorizations are commonly made regarding efficacy and toxicity without attention to differences between studies. Furthermore, treatments that have recently achieved regulatory approval with stringent independent assessment of pathology response are viewed as less established, or inferior to combination therapy.
Aims: In the effort to take a critical and comprehensive evidence-based approach to available standards in R/R PTCL we developed an objective scoring system for all types of studies published in the literature (*e.g.*, randomized phase 3, case match control, phase 2, phase 1, case reports and small series) to aid decision-making based on an assessment of all the available data.
Methods: We performed an extensive review on PubMed of the clinical trials published in the literature that included patients with R/R PTCL. We proposed a rigorous scoring system based on a survey from nearly 100 authorities in the field to assess the scientific impact of each study based on the agreed study characteristics, including type of study (*i.e.*, randomized

phase 3, case match control analysis, phase 2 weighted based on number of PTCL patients [≥100 *vs* <100 patients], phase 1 with ≥5 or <5 PTCL patients enrolled, and retrospective) weighted based on percent of PTCL patients included; weighting for inclusion of central pathology or response review; weighting for detailed reporting of study metrics (ORR, CR, DoR, PFS). The scoring system included a penalty of -0.5 each for ORR, DoR, or PFS not being reported and -0.2 for omitting previous lines of therapy. Studies that ranked 0 or below were all grouped under the minimum score of 0. The proposed scoring system was evaluated by a panel of experts belonging to different academic institutions in three different continents, actively involved in T-cell lymphoma clinical research. The scoring system was modified accordingly based on recommendations made by 2 or more of the panel members.

Results: We identified 58 original publications between 2004 and 2018 that involved clinical studies enrolling patients with R/R PTCL. The scoring system spanned from 0 to 9. Interestingly only 12 of the 58 studies had a score above 5; 15 out of 58 studies had a score between 1 and 5; and the remaining publications all scored between 0 to 1.

Summary/Conclusion: When compared to standard recommendations reported by various societies, our analysis suggests most practice patterns are based on studies with low priority scores, and underweight more robust clinical experiences. This analysis aims to guide physicians in critically evaluating the published literature when choosing salvage therapy for patients with R/R PTCL.

Salamanca, Salamanca, [9]S° Hematología, H.U. Canarias, Tenerife, [10]S° Hematología, Hospital del Mar, Barcelona, [11]S° Hematología, Hospital Clínico Valencia, Valencia, [12]Medical Department, Janssen, Madrid, Spain

Background: Most of the patients with MCL have an unfavorable prognosis. It is a heterogenous disease that remains incurable despite progress in therapies developed with quite heterogeneous approaches in frontline and relapse scenarios.

Aims: This retrospective, multicentre, observational study describes and analyses the therapeutic strategies and their results in MCL from first line and beyond in routine clinical practice in Spain.

Methods: Patients included were diagnosed since 2005, older than 18 years with relapsed/refractory MCL and followed during a minimum of 6 months after the last treatment received. Quantitative variables were described by measures of central tendency and dispersion and qualitative variables by absolute and relative frequencies. Survival analysis were made by Kaplan-Meier Method. Analysis done with SPSS v18.0

Results: Primary endpoint: efficacy of treatments in terms of response, progression free and overall survival. **Secondary endpoints:** Description of demographic characteristics, morbidities, treatments and safety profile. 67 patients were analysed: 43 not candidates and 24 candidates to intensive therapy at diagnosis. Median age was 71 (range, 42-90 yo), blastoid histology 40%, 93% extranodal disease (86% bone marrow, 48% gastrointestinal) and 40% high-MIPI. Comorbidities: hypertension (43%), cardiovascular disease (40%), AF/Flutter (18%), thrombosis (12%) and liver disease (12%). Most concomitant treatments were: antihypertensive therapy 45%, antidepressants 38%, anticoagulants 34% and 24% antiplatelet agents. Treatment decisions were made by: routine clinical practice (2/3), clinical protocol (1/3). None treatment was discarded due to economic issues. *Main treatments in first line were*: R-CHOP (54%), R-HyperCVAD or R-CHOP/R-DHAP (39%), R-CVP (5%) and R-Bendamustine (3%), 19% received rituximab maintenance and 18% ASCT. For *second line*: R-Bendamustine (30%) and R-GemOX (19%), 21% patients received rituximab maintenance, 5% ASCT and 5% alloSCT. The rest were highly variable. For *third line*: R-Bendamustine (29%), ibrutinib (16%), temsirolimus (11%), radiotherapy (11%), 2% ASCT and 4% alloSCT. *In 4th line*, R-Bendamustine (33%), bortezomib combinations (25%) and ibrutinib (13%). Survival results with every line according to non-candidates /candidates to intensive therapy are shown in the table below.

Table 1.

Non candidates	N	Treatment duration (m, median [min-max])	Response (%)	CR (%)	PFS (m, median [95%CI])	Overall survival (m, median [95%CI])
First line	43	4,3 (0,7 – 30,9)*	79,1*	44,2*	19,5 (14,6 – 24,5)*	74,6 (41,1 – 108,2)
Second line	43	4,6 (0,2 – 41,9)	67,4	39,5	22,5 (15,6 – 29,4)	93,1 (1,3 – 64,8)
Third line	20	4,6 (0 – 15,3)	48,2	24,1	9,2 (6,6 – 11,8)	10,4 (2,9 – 17,9)
Fourth line	10	3,1 (0,1 – 14,9)	25,1	6,3	3,4 (0,4 – 6,4)	5,0 (0 – 20,6)
Fifth line	8	0,7 (0 – 5,7)	25	0	1,5 (1,5 – 1,6)	5,5 (0 – 11,1)
Sixth line	3	5,5 (1,9 -9)	1 patient	0	2 patients progression/exitus	2 patients exitus

Candidates	N	Treatment duration (m, median [min-max])	Response (%)	CR (%)	PFS (m, median [95%CI])	Overall survival (m, median [95%CI])
First line	24	7,0 (2,4 – 27,5)	91,7	79,2	35,9 (22,2 – 49,5)	NR
Second line	24	4,2 (0,3 – 47,7)	70,9	66,7	27,3 (11,1 – 43,6)	63,4 (33,5 – 93,4)
Third line	10	2,3 (0,1 – 16,9)	50,3	43,8	16,0 (4,3 – 28,9)	32,5 (20,4 – 44,6)
Fourth line	8	4,5 (1,8 – 6,5)	37,5	37,5	12,8 (2 – 23,7)	20,1 (9,2 – 31,1)
Fifth line	5	4,7 (0,5 – 8,9)	27	20	22*	27,9 (12,4 – 43,5)
Sixth line	3	6,9 (0,7 – 13,2)	2 patients	0	2 patients progression/exitus	2 patients exitus

*p=0,05 candidates vs. non candidates for intensive treatment; NR: not reached. *Standard error not available due to low N of patients

Summary/Conclusion: This study shows the highly heterogenous treatments in MCL in a sanitary scenario without economic restrictions. Overall survival differs according to intensive *versus* non intensive treatment in first line and, it markedly decreases from the second line onwards, especially in older patients. We need new therapeutic targets to improve the current outcomes.

PB1770

A PHASE 3 STUDY COMPARING POLATUZUMAB VEDOTIN PLUS R-CHP *versus* R-CHOP IN PATIENTS WITH DLBCL (POLARIX)

H. Tilly[1,*], C. Flowers[2], J.W. Friedberg[3], C. Herbaux[4], F. Morschhauser[4], L.H. Sehn[5], J. Sharman[6], M. Trněný[7], L. Wang[8], C. Lee[8], G. Salles[9]

[1]Centre Henri Becquerel, ROUEN CEDEX, France, [2]Winship Cancer Institute of Emory University, Atlanta, [3]University of Rochester Medical Center, Rochester, United States, [4]University of Lille, CHU Lille, Lille Cedex, France, [5]BC Cancer Agency, Vancouver, Canada, [6]US Oncology and Willamette Valley Cancer Institute, Springfield, United States, [7]Charles University, Prague, Czech Republic, [8]Genentech, Inc., South San Francisco, United States, [9]Hospices Civils de Lyon, Université Lyon-1, Lyon, France

Background: R-CHOP remains the standard of care in patients with previously untreated diffuse large B-cell lymphoma (DLBCL). However, patients with high-risk disease have poorer outcomes with R-CHOP. Polatuzumab vedotin (pola) is an antibody-drug conjugate targeting CD79b; it delivers the antimitotic agent MMAE and is being evaluated as a replacement strategy for vincristine within the R-CHOP regimen. In a phase Ib/II study in higher risk DLBCL patients, pola + R-CHP produced promising efficacy across different subtypes of DLBCL and a safety profile similar to that observed in the R-CHOP arm of the GOYA study (Tilly H, *et al.* Hematol Oncol 2017; Vitolo U, *et al.* J Clin Oncol 2017).

Aims: To evaluate the efficacy and safety of pola plus R-CHP compared with R-CHOP in patients with previously untreated DLBCL to see whether pola can improve outcomes in patients with low to high-risk disease.

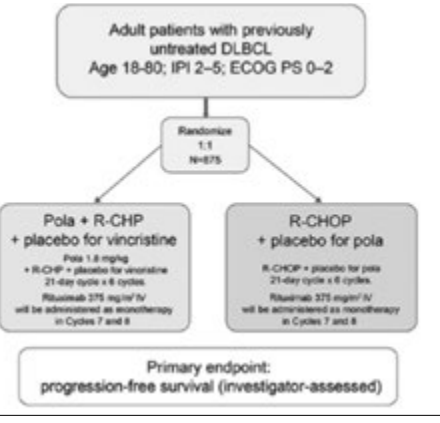

Figure 1.

Methods: This is a multicenter, randomized, double-blind, placebo-controlled, phase 3 study in patients with previously untreated DLBCL. Patients (planned N=875) aged 18-80 years with CD20-positive DLBCL (including DLBCL not otherwise specified [NOS], germinal center B-cell like [GCB],

and activated B-cell like [ABC] subtypes), ECOG performance status 0-2, and IPI score 2-5, will be randomized 1:1 to one of two treatment groups, stratified by IPI score (2 *versus* 3-5), bulky disease and geographical region (Figure). Arm A will receive pola 1.8 mg/kg on Day 1 plus R-CHP (standard dosing schedule) plus vincristine placebo for 6 cycles; Arm B will receive R-CHOP (standard dosing schedule) with pola placebo for 6 cycles. In both arms, R will be administered as monotherapy in cycles 7 and 8. The primary endpoint is progression-free survival (PFS), as assessed by the investigator, using the Lugano classification (Cheson B, *et al.* J Clin Oncol 2014). Secondary endpoints include PET-CT complete response rate at end of treatment assessed by an independent review committee, event-free survival due to efficacy reason, 2-year PFS rate, and overall survival. PET-CT and CT scans will be obtained at screening, after 4 cycles (planned interim assessment), and 6–8 weeks after end of study treatment. Patient follow-up will continue for 5 years after end of treatment.
Results: Enrolment began November 2017.
Summary/Conclusion: This phase 3 study, POLARIX, will evaluate clinical outcomes with pola plus R-CHP compared with R-CHOP in patients with previously untreated DLBCL. Clinical trial information: the study is funded by F. Hoffmann-La Roche Ltd; NCT03274492.

PB1771

CUTANEOUS MANIFESTATIONS OF ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

N. Chernova[1,*], M. Sinitcina[2], Y. Sidorova[3], N. Soboleva[4], A. Sudarikov[3], A. Kovrigina[2], E. Zvonkov[1]

[1]Department Chemotherapy of Lymphomas, [2]Department of Pathology, [3]Department of Molecular Hematology, [4]Clinical diagnostic laboratory, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare form of non-Hodgkin's lymphoma, characterized by generalized lymphadenopathy and frequent extra nodal sites. Cutaneous lesions of AITL are observed in 38-58% of pts and often precede lymphadenopathy.
Aims: The aim of our study is to identify the genesis of cutaneous lesions of AITL.
Methods: Clinical data of 54 patients with newly diagnosed AITL we analyzed. Diagnosis was based on standard WHO criteria. The male/female ratio was 30/24; median age was 61 (29-81) years. Histological, molecular studies of skin biopsies were performed. To evaluate T-cell clonality TCRG and TCRB gene rearrangements were PCR-amplified according to BIOMED-2 standardized protocol and analyzed by capillary electrophoresis on ABI PRISM 3130 (Applied Biosystems). Sensitivity of T-cell clonality assay was limited to 10% of clonal -cells of the total T lymphocytes in the sample. Gly17Val RHOA mutation was analyzed by quantitative allele-specific (qAS) TaqMan Real-Time PCR assay. The detection level of this method was 1% of mutated cells in the total cell population.
Results: Cutaneous lesions were observed in 24 (44.4%) of 54 pts, they were more common in males (75%) than females (25%). Maculopapular rash was noted in 22 (91.7%) of 24 cases. Morphological and molecular studies of skin biopsies with maculopapular rash demonstrated reactive changes. The level of polyclonal IgE was elevated in patients with maculopapular rash. Tumor cutaneous lesions were detected in 8 (14.8%) of 54 pts and were represented by "livedo reticularis" in 3 cases, focal hyperpigmentation-in 2, erythroderma-in 1, tumor node-in 1 and plaques-in 1. Tumor and reactive cutaneous lesions were presented in 6 pts, in 4 (7.4%) of 54 cases they were noted at the same time. The type of cutaneous elements changed during of the disease in 3 (5.6%) pts.
Summary/Conclusion: Maculopapular rash is the most frequent cutaneous manifestation of AITL and it has a reactive genesis. Tumor lesion of the skin is rarely and can manifest by various cutaneous elements. In some cases AITL tumor and reactive cutaneous lesions can be observed simultaneously or sequentially.

DA -EPOCH- R CAN CAUSE ADRENAL INSUFFICIENCY IN NON-HODGKIN'S LYMPHOMA PATIENTS

I. Vaxman[1,2,*], O. Katz-Beyar[3,4], A. Gafter Gvilli[1,5], A. Grossman[1,6], A. Schlesinger[1,7], N. Horowitz[3], O. Pasvolsky[1,2], E. Joffe[1,2], P. Raanani[1,2], U. Rozovski[1,2], M. Lahav[1]

[1]Sackler School of Medicine, Tel Aviv University, Tel Aviv, [2]Institute of Hematology, Beilinson, Petah tikva, [3]Rappaport Faculty of Medicine, [4]Department of Hematology and Bone Marrow Transplantation, Technion, Haifa, [5]Medicine A, [6]Medicine B, Rabin Medical Center, Petah tikva, [7]Home care unit of sharon shomron, Sharon Shomron, Tel Aviv, Israel

Background: Adrenal insufficiency (AI) is caused by insufficient production or action of glucocorticoids. The most frequent cause of AI is high dose and prolonged use of corticosteroids. However, there is evidence that even shorter periods of corticosteroid therapy may affect adrenal function. The standard protocol for diffuse large B cell lymphoma (DLBCL) is 6 to 8 cycles of R-CHOP (rituximab, cyclophosphamide, doxorubicin, vincristine, prednisone), which includes five days of prednisone at a dose of 100 mg/d. DA- EPOCH- R (rituximab, etoposide, doxorubicin, vincristine, cyclophosphamide and prednisone) is an alternative protocol used in patients with aggressive lymphomas and especially for primary mediastinal B cell lymphoma (PMBCL). The protocol consists of higher doses of prednisone compared to R-CHOP (five days of prednisone 60 mg/m^2 twice daily). In both regimens, there is no recommendation for tapering down of corticosteroids or assessment of potential AI. Because the DA -EPOCH-R protocol includes higher dose of corticosteroids we hypothesized that it may induces higher rates of AI.
Aims: To determine the incidence of AI in non-Hodgkin's lymphoma (NHL) patients treated with R-CHOP or DA- EPOCH- R.
Methods: We prospectively enrolled patients with newly diagnosed NHL that received either DA-EPOCH- R (study group) or R- CHOP (control group) protocols. We excluded patients with known adrenal disorders, patients receiving corticosteroid treatment at any time during the past six months, known adrenal involvement with lymphoma and treatment with drugs that are known to cause a false positive ACTH test. We evaluated adrenal function by 250 microgram ACTH tests at 5 time points: prior to first treatment cycle, on day 5 or 6 of the cycle and 21 after the first cycle, at the completion of the 5th cycle and on the first day of the 6th cycle. A positive ACTH test was defined as a cortisol level of less than 500 nmol/liter at least in one of these test.
Results: Between May 2015 and May 2017, ten patients who received DA-R-EPOCH and 17 patients who received R-CHOP were enrolled. The median age at time of diagnosis was 60 years (range: 21-89) and 52% (14 patients) were females. The diagnosis was DLBCL in 19 patients and other (PMBCL, follicular lymphoma grade 3a, primary effusion lymphoma) in 8 patients. There was no difference between the two groups with regards to baseline characteristics in terms of blood pressure, hemoglobin or platelet levels, white blood cells, eosinophils, glucose, sodium or potassium levels. However, patients in the control group that received R-CHOP were significantly older than those in the DA- EPOCH- R arm (the median age was 63 in R-CHOP group and 34 in DA-EPOCH-R, p=0.001). Out of the 27 patients included in the trial 2 died at the time of data collection, both were in the R-CHOP arm. ACTH test was positive at least once during the study follow-up in 9 patients -7 patients who received DA -EPOCH-R and 2 patients who received R-CHOP (P=0.04). Tests were mostly positive on day 5 (8 patients. Patients with positive ACTH test were more likely to develop fever during treatment (P=0.04), but did not develop overt electrolyte disturbances, reduced mean arterial pressure or elevated eosinophil levels.
Summary/Conclusion: Our study demonstrates that patients who received DA- EPOCH- R were more likely to develop AI. We believe that clinicians should be aware of this limited adrenal response to stress and that the option of AI as an alternative cause of fever in these patients should be considered.

PB1773

PRIMARY PANCREATIC LYMPHOMA: REPORT ON 10 CONSECUTIVE PATIENTS

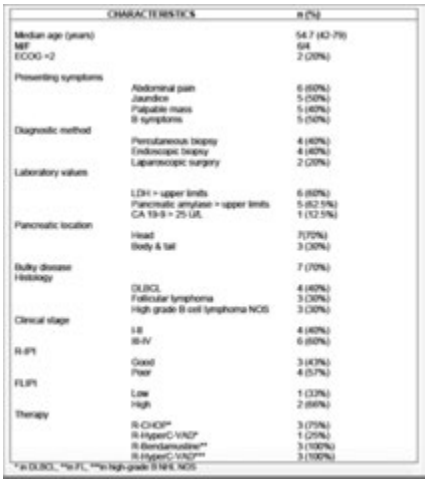
D. Facchinelli[1,*], A. Polino[1], A. Borin[2], E. Boninsegna[3], M.C. Tisi[4], C. Visco[4], M. Krampera[1], C. Tecchio[1]

[1]Department of Medicine, Section of Hematology, [2]Department of General and Pancreatic Surgery, [3]Department of Radiology, University of Verona, Verona, [4]Department of Medicine, Section of Hematology, San Bortolo Hospital, Vicenza, Italy

Background: Primary Pancreatic Lymphoma (PPL) is a very rare disease, representing only 0.1% of lymphomas and 0.2% of pancreatic tumors. According to the WHO classification the diagnostic criteria for PPL are: i) the bulk of the disease has to localize in the pancreas; ii) although adjacent and distant spread may be exist the primary clinical presentation has to involve the pancreatic gland. PPL presentation is variable and may overlap the onset of other neoplastic or inflammatory pancreatic diseases, often resulting in diagnostic difficulties. Histopathological examination usually reveals a diffuse large B cell lymphoma (DLBCL), nonetheless other types of lymphomas have been reported including the indolent ones. Diagnosis can be obtained through a percutaneous/endoscopic ultrasound-guided biopsy or surgery. An accurate histological characterization is essential because, unlike epithelial tumors, PPL does not benefit from surgery.

Aims: to evaluate retrospectively clinical, laboratory and histological characteristics, diagnosis, treatment, and outcome of a series of PPL patients diagnosed in 2 hematology units.
Methods: patients diagnosed with PPL between 2008 and 2017 were retrieved from the medical record databases of the Verona and Vicenza Hematology Units. Inclusion criteria were the availability of information related to clinical onset, histopathological diagnosis, laboratory tests, radiology imaging, treatment and follow-up. Patients with secondary pancreatic involvement of lymphoma were excluded. All cases herein presented were revised to ensure that they fit the latest WHO criteria for PPL.
Results: 10 patients with PPL were identified: median age was 54 years, 6 patients were males. Clinical manifestations included abdominal pain, jaundice, a palpable epigastric mass and systemic symptoms. None of these patients had a history of previous pancreatitis, one had a positive serology for hepatitis B. Laboratory tests evidenced a normal hemogram in all cases, while LDH and pancreatic amylase were augmented in 6 and 5 patients, respectively. CA 19-9 was slightly increased in 1 patient only. The histopathological diagnosis was obtained by percutaneous or endoscopic biopsy or surgery and revealed: DLBCL (n=4), follicular lymphoma (FL) (n=3) and high-grade B-cell lymphomas not otherwise specified (n=3). In 7 cases PPL was bulky and occupied the pancreatic head. All patients underwent a first line immune-chemotherapy: R-Bendamustine (n=3), R-CHOP (n=3) or R-HyperC-VAD (n=4). Only 2 patients with a histopathologica diagnosis of FL achieved a complete remission (20%). The 7 patients with aggressive lymphoma had a median progression free survival of 4 months and an overall survival of 24 months.

Table 1.



CHARACTERISTICS		n (%)
Median age (years)		54.7 (42-79)
M/F		6/4
ECOG >2		2 (20%)
Presenting symptoms		
	Abdominal pain	6 (60%)
	Jaundice	5 (50%)
	Palpable mass	5 (40%)
	B symptoms	5 (50%)
Diagnostic method		
	Percutaneous biopsy	4 (40%)
	Endoscopic biopsy	4 (40%)
	Laparoscopic surgery	2 (20%)
Laboratory values		
	LDH > upper limits	6 (60%)
	Pancreatic amylase > upper limits	5 (62.5%)
	CA 19-9 > 25 UI/L	1 (12.5%)
Pancreatic location

	R-CHOP*	3 (75%)
	R-HyperC-VAD*	1 (25%)
	R-Bendamustine**	3 (100%)
	R-HyperC-VAD**	3 (100%)

*in DLBCL, **in FL, ***in high-grade B NHL NOS

Summary/Conclusion: PPL represents a rare and difficult-to-recognize disease. Most patients in our series complained symptoms characteristics of pancreatic adenocarcinoma such as abdominal pain, jaundice, and weight loss. However increased LDH serum levels and normal CA19-9 were associated to a diagnosis of NHL, as confirmed by histopathological analysis. The poor outcome of patients with high-grade PPL suggests the need of aggressive first-line immune-chemotherapy regimens, possibly followed by autologous stem cell transplantation. Obviously larger series of patients are awaited in order to drawn definitive conclusions on this rare extranodal NHL.

PB1774

PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA-THE ROLE OF MEDIASTINAL RADIATION

S. Afonso*, I. Carvalhais, A. Carneiro, F. Príncipe, J.E. Guimarães

Department of Clinical Hematology, Centro Hospitalar de São João, Porto, Portugal

Background: Primary mediastinal large B-cell lymphoma (PMLBCL) is a rare subtype of diffuse large B-cell lymphoma. The most standard approaches include a combination of immunochemotherapy and mediastinal radiotherapy (RT).
Aims: Because mediastinal RT is associated with significant long-term toxicities, it was necessary the development of effective therapeutic strategies (rituximab with increased dose intensity regimens) that changed the need for routine RT.
Methods: Fifteen patients with diagnosis of PMLBCL between 2005-2015 were treated according to protocol R-DA- EPOCH (infusional dose-adjusted etoposide, doxorubicin and cyclophosphamide with vincristine, prednisone and rituximab). Patients were classified into 3 risk groups (according to presence of pleural/pericardial effusion and IPI high/intermediate-risk or high-risk). Residual disease (RD) was evaluated by FDG-PET scan and defined as score 2 according to Deauville Criteria and partial response (PR) defined as score 4-5 with a reduction >50% in size of mass.
Results: Median age at diagnosis was 29 (21-43) years, 86.7% of patients were aged<40 years (n=13). Eleven patients (78.6%, n=14) had bulky disease (tumor mass ≥10 cm) and 6 (42.9%, n=14) had superior vena cava syndrome (SVCS) at presentation. Presence of pleural/pericardial effusion in 7 patients (53.8%, n=13) and pulmonary involvement in 5 (38.5%, n=13). According to the prognostic score, two patients (15.4%) were classified as high risk (2 adverse factors), five (38.5%) in intermediate risk (1 factor) and six (42.2%) in low risk (0 factors). All patients were treated with 6 cycles of immunochemotherapy. Seven patients (46.7%) achieved complete response (CR), confirmed by FDG-PET in five. Another 3 (20%) had RD. All patients who achieved CR/RD did not perform RT with an event-free survival (EFS) of 100%. PR was attained in 3 patients (20%), two had high-risk disease. All patients in PR were submitted to RT, reaching CR (confirmed by FDG-PET) without relapse during the follow-up time. Progressive/stable disease was observed in 2 patients (13.3%). They were submitted to autologous stem cell transplant reaching CR. With a median follow-up of 64 (26-128) months, an overall survival/EFS of 100% was reached without evidence of disease. No cardiac events or secondary tumors were observed, so far.
Summary/Conclusion: The use of therapeutic approaches with rituximab and increased dose intensity regimens (like R-DA-EPOCH) has shown excellent efficacy and challenge the need for mediastinal radiation (5-years OS and EFS >90%, according to data from several studies). In conclusion, our results indicate that patients who had CR/RD evaluated by FDG-PET after treatment with R-DA-EPOCH, attained an EFS was 100% with a median follow up of 64 months. In these patients, the use of R-DA-EPOCH obviated the need for routine mediastinal RT. In patients with persistent disease after treatment, RT is a necessary approach though.

PB1775

R-DA-EPOCH AS OUTPATIENT REGIMEN FOR AGGRESSIVE NON HODGKIN B CELL LYMPHOMA: A SINGLE CENTER EXPERIENCE

F. Cocito[1,*], I. Casaroli[1], E. Doni[1], F. Rossini[1], L. Verga[1], A. Aroldi[1], F. Brioschi[1], C. Borella[1], C. Gambacorti Passerini[1,2], B. Silvia[1]

[1]Hematology, Ospedale San Gerardo-ASST Monza, [2]Department of Internal Medicine, University of Milano-Bicocca, Monza, Italy

Background: R -CHOP still remains the standard of care for large B cell Lymphoma(LBCL) patients(pts) but it's clearly unsatisfactory for about 30-40% of them, especially for pts characterized by high-risk molecular profile,carrying expression of MYC and BCL2 proteins (Double Expressor Lymphoma[DEL]) associated or not to the underlying translocation(Double Hit Lymphoma[DHL]).More intensive programs and in particular R-DA-EPOCH scheme obtained good results in retrospective studies. We report our prospective experience with this program.
Aims: to analyze the outcome in terms of response, Progression free survival (PFS), Overall Survival (OS), feasibility and toxicity of consecutive pts with Diffuse Large B cell Lymphoma(DLBCL),High grade Lymphoma(HGL) or Primary mediastinal B cell Lymphoma(PMBCL) diagnosed in a single Italian hematological center and all treated with the R-DA-EPOCH, which was delivered either as an inpatient regimen or administered on an outpatient basis using ambulatory infusion pumps.
Methods: We reviewed chart data of 36 LBCL pts consecutively diagnosed from December 2014 to February 2018 at our center. For pts diagnosed since 2016 we introduced the new category of HGL according to WHO 2016.
Results: Median follow up of our pts is 533 days (42 -1154). Regarding pts characteristics 23/36 (63.9%) are male, 13/36 (36.1%) female. Response is available for 33/36 pts, 1 is waiting for restaging and 2 pts are still receiving therapy at time of analysis. Median age at diagnosis was 50 years(range 22-69). Considering histology 23/36 (63.9%) were DLBCL, 6/36(16.7%) HGL and 7/36 (19.4%) PMBCL. Median ki67% was 80% (range 50- >90). Regarding molecular profiles a total of 18/36 (50%) pts show bcl2 expression,28/36 (77,8%) are bcl6 and 7/36 (19,4%) myc positive. In our series 4/36(11,1%) pts were DEL (bcl2 and myc positive) but FISH data were available only for 2 pts and only 1 resulted DHL. Regarding the disease stage 17/36(47,2%) have IPI score 0-2 and 19/36 (52,8%) IPI score 3-5. Twenty out of 36 pts (55,6%) have an extra-nodal (EN) localization at diagnosis; 15/36 (41,7%) >1 EN localization. Of note 4/36 (11,1%) were HIV positive pts. Data regarding the feasibility of this approach are available for all pts: 28/36(77,8%) pts completed six planned cycles and 23/36(63,9%) received therapy on an outpatient basis (123 outpatient cycles administrat-

ed).Four pts didn't complete 6 cycles because of disease progression. Dose escalation was possible in 23/36(63.9% [95% C.I. 57%-85%]) pts, but rarely in pts >65 yrs (only in 2/36 [5,6%, 95% C.I. 1.7%-17%]). The median dose level reached was 2 (range level -1-5). Grade4 neutropenia occurred in 36/36 (100%)pts, thrombocytopenia grade 4 in 8/36 pts (22,2%). A total of 15/36 (41,7%) pts had an infectious event and 10/36(27.8%) had therapy delay due to toxicities. Grade 3/4 non-hematological toxicities, especially neurotoxicity, were infrequent and manageable. We observed cardiotoxicity in 2/36 pts, which was related to tumor lysis syndrome and HIV infection. Among pts evaluable for response, 27/33(81,8%) obtained a complete remission (CR). A total of 6/36 pts died, all due to disease progression. PFS at 2 years was 74,7% (Figure 1). OS at 2 years 77%.

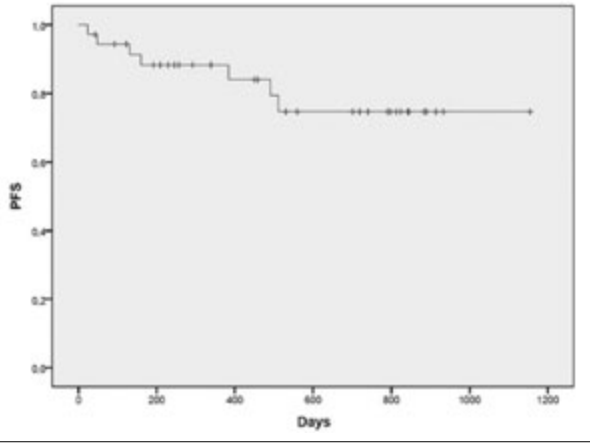

Figure 1.

Summary/Conclusion: Our results confirm R-DA-EPOCH as a feasible program with promising response rate.This scheme allows to obtain CR in 81,8% of pts with an acceptable toxicity profile. Especially in patients with high risk DLBCL (high IPI score, DEL and DHL) R-DA-EPOCH is an alternative to standard induction therapy which can be administered as an outpatient regimen in the majority of pts.

PB1776

R-HCVAD/MTX-ARA-C AND AUTOLOGOUS STEM CELL TRANSPLANTATION IN MANTLE CELL LYMPHOMA-RETROSPECTIVE ANALYSIS OF A SINGLE INSTITUTION EXPERIENCE IN THE RITUXIMAB ERA

P. Chorão[1,*], M. Badior[2], I. Carvalhais[1], A. Carneiro[1], F. Príncipe[1], J.E. Guimarães[1,3]

[1]Clinical Hematology Department, Centro Hospitalar São João, Porto, [2]Clinical Hematology Department, Centro Hospitalar Vila Nova de Gaia/Espinho, Gaia, [3]Faculty of Medicine of Porto University, Porto, Portugal

Background: In fit patients with mantle cell lymphoma (MCL), intensive chemotherapy containing rituximab (R) and cytarabine (Ara-C) followed by autologous stem cell transplantation (ASCT) is the backbone for treatment. Despite new data on novel induction schemes, reports on R-HCVAD/MTX-Ara-C (R-hyperfractionated-cyclophosphamide-doxorubicin-vincristine-dexamethasone and R-methotrexate-Ara-C) are lacking.
Aims: To analyze the outcome of MCL patients treated with R-HCVAD/MTX-Ara-C followed by ASCT.
Methods: From 2005 to 2017, data on MCL patients treated with R-HCVAD/MTX-Ara-C (3+3 cycles) followed by BEAM (BCNU, Etoposide, Ara-C, Melphalan) and ASCT was retrospectively analyzed. Five-year survival (5y-OS) and progression free survival (5y-PFS) from time of ASCT was calculated.
Results: A total of 28 patients (6 were external referrals) received induction with R-HCVAD/MTX-Ara-C. Median age was 60 years (interval 42-68) and 71% were male. At diagnosis, 96% had Ann-Arbor stage IV, 50% had B symptoms, 93% had ECOG performance status<2, 39% had increased lactic dehydrogenase, 57% had leukemic expression and 32% gastrointestinal invasion. MIPI was low-risk (LR) in 39%, intermediate-risk (IR) in 25% and high-risk (HR) in 36%. For the 22 patients treated in our institution, overall response rate was 86% with complete response (CR) rate of 64%. Three patients died due to disease progression (2 during treatment) and 1 patient was ineligible for ASCT because of cardiovascular toxicity. The 6 patients externally referred to ASCT were all in CR. Of the 24 patients who were submitted to ASCT the median age at transplantation was 60 years (17% had >65 years) and MIPI was LR in 46%, IR in 25% and HR in 29%. All patients made successful peripheral blood stem cell progenitors (PBSCP) harvest, 71% at the secondo R-MTX-Ara-C and the remaining in following cycles. Only 2 patients required plerixafor in addition to G-CSF. Median harvest for infusion was $2.90x10^9$ CD34+ cells per kilogram (interval 2.08-7.70), with no differences between harvesting at the second R-MTX-Ara-C or after (p=0.260). There was no mortality associated with BEAM conditioning and ASCT. All engraftments were successful, with median time to neutrophil recovery of 11 days (interval 9-14) and to platelet recovery of 17 days (interval 12-42). At the time of analysis, data was available on 22 patients (2 have yet to reach 100 days after ASCT). CR rate at +100 day was 100%, with 63% 5y-PFS and 77% 5y-OS after ASCT. Five patients relapsed and 4 deaths occurred (2 from lymphoma relapse and 2 due to secondary solid malignancies). Patients with HR MIPI had worst outcomes (median OS HR 58 months *versus* LR/IR not reached, p=0.007). Patients older than 60 years had inferior 5y-PFS (35% [median 59 months] for >60 years *versus* 82% for ≤60 years, p=0.022) but similar 5y-OS (57% *vs* 90%, p=0.060).
Summary/Conclusion: Even in an older and higher risk patient cohort, our results show similar outcomes to other induction schemes. R-HCVAD/MTX-Ara-C followed by ASCT remains a practical option for fit MCL patients.

PB1777

SERUM ALBUMIN IS A STRONG PREDICTOR OF SURVIVAL IN PATIENTS WITH DIFFUSE LARGE B CELL LYMPHOMA TREATED WITH R-CHOP

L. Villela[1,*], E. Montaño[2], G. Ruiz-Argüelles[3], S. Baltazar[4], A. Isassi-Chapa[5]

[1]Hematology and blood bank of Centro Medico Dr. Ignacio Chavez, ISSSTESON, ISSSTESON, HERMOSILLO, [2]Hematology Service, Hospital General de México, Hospital Dr. Eduardo Liceaga, Ciudad de México, México, Secretaria de Salud, Mexico City, [3]Clinica Ruiz de Puebla, Clinica Ruiz de Puebla, Puebla, [4]Hematology Department, UMAE [25] IMSS, [5]Hematology and oncology department, ITESM, Monterrey, Mexico

Background: Traditional International Prognostic Index before (tIPI) and post-rituximab era[Revised IPI (R-IPI) and enhance National Cancer Comprehensive Network-IPI (NCCN-IPI)] has been used to obtained risk groups for overall survival (OS) and progression free survival (PFS). Serum albumin (SA) has proven to be a prognostic marker in many hematological malignancies, including diffuse large B-cell lymphoma (DLBCL), but it was not analized in any IPI. SA could be a surrogate for age, poor nutritional status, comorbid status, and aggressive disease.
Aims: Analyze in DLBCL patients the predictive factor of albumin in relation to OS.
Methods: From 2010 to 2016, 5 databases of public and private institutions from 4 different states were analyzed retrospectively. Where *de novo* DLBCL patients were identified and obtained 113 from 160 patients with next inclusion criteria: 18 years old and older, and R-CHOP treatment. Minimum the following clinical data for calculating tIPI,R-IPI and NCCN-IPI : Age, lactic dehydrogenase (LDH), performance status (PS, ECOG scale), number of extranodal disease (EN), Ann Arbor stage (localized *vs* Advance), and others like SA. Diagnosis of DLBCL was confirmed through review the initial pathology report. 47 patients were excluded because they did not have some variable before mentioned. Primary clinical outcome was defined as date of diagnosis to date of death or date of last contact for those censored. For the descriptive statistics the square Chi was used. Time-to event data (OS) were estimated using the KaplanMeier method. Hazard Ratios (HR) were used to identify potential risk factors in different risk groups conformed. To obtain a correct cut-off point for albumin, we used the ROC curve and later we evaluated the best positive and negative likehood ratio (LHR+ and LHR-, respectively).
Results: From 113 DLBCL-patients, median age was 56.5 (range: 19-89); 52% were women; 58% were advanced stage (III/IV Ann Arbor); age >60 y/o,47%, but 15% >75 y/o; ECOG 2, 28.3%; EN disease (≥1), 35.5%; LDH elevated, 57.2%; Albumin<4g/dL, 46%. The median follow-up of whole series was 19 months; the median follow-up depending on the response after treatment was for complete response (CR): 32 months, partial response (PR): 13.6 months and Progression/failure (P): 8 months. The OS curves creation for tIPI, R-IPI and NCCN IPI was in accordance with already reported in other series. The cut-off point for albumin using the ROC curve was ≤3.7g/dL (Sensitivity 63.4%, Specificity 80.6, AUC 0.77; p<0.001). Interestingly, the LHR+ in 19.32 and LHR- in 0.74 were found in accordance to 2.7g/dL cut-off point of albumin, thus identifying a value lower than the original point of 3.7 of albumin that could be associated with higher mortality. Then, we

can build two risk groups: one called low (3.7 to 2.8g/dL) and another ultra low-albumin (≤2.7g/dL). When we capture these groups in the OS curves, 3 groups can be identified perfectly (Figure 1).

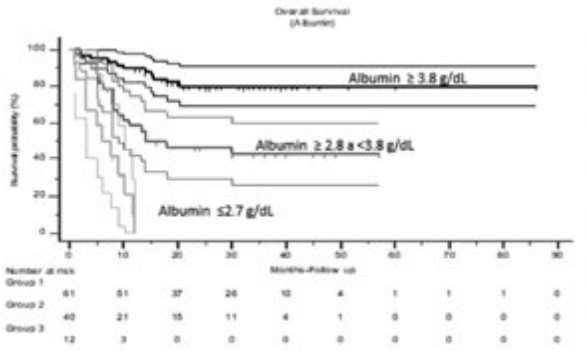

Figure 1.

Summary/Conclusion: The low and ultra low levels of serum albumin are a strong predictive factor for the early mortality of patients with DLBCL. These findings guarantee to evaluate this biomarker more closely

PB1778

FEASIBILITY OF PIXANTRONE CONTAINING R-CPOP AS FIRST LINE TREATMENT FOR PATIENTS WITH AGGRESSIVE B CELL LYMPHOMA WITH CONGESTIVE HEART FAILURE OR AT RISK OF ANTHRACYCLINE INDUCED CARDIOTOXICITY

R. Marks*, T. Strüßmann, U. Krohn, J. Duyster, J. Finke, K. Fritsch

University Hospital Freiburg, Freiburg, Germany

Background: Anthracyclines are essential in the treatment of aggressive B cell Non Hodgkin Lymphoma (NHL). Nevertheless, in clinical practice the substantial risk of developing drug induced cardiotoxicity, in particular congestive heart failure (CHF), results often in ommission of anthracyclines in first line treatment of this otherwise curable malignant lymphomas in patients at risk. Known cofactors for developing anthracycline induced CHF are cumulative anthracycline dose, female sex, age >65, diabetes, impaired cardiac function, and hypertension. No standard treatment for patients with aggressive B cell NHL having one of this cofactors exist. Pixantrone is an aza-anthracenedione showing reduced cardiotoxicity *in vitro* compared to standard anthracyclines. Recent data by Herbrecht *et al.* (Ann Oncol, 2013, 24:2618) showed that first line combined rituximab based immunochemotherapy treatment for DLBCL with the R-CPOP protocol (derived from R-CHOP in which doxorubicin is substituted with pixantrone 88mg/m^2) resulted in similar PFS when compared with R-CHOP, while reduced grade 3 CHF rates could be observed.
Aims: We wanted to explore the feasibility of R-CPOP treatment in aggressive B cell NHL patients with cofactors for developing anthracycline induced CHF.
Methods: In an unicenter setting we started in 2015 to use this protocol (6 cycles CPOP, 8x rituximab, every three weeks) in ten patients. Diagnoses included DLBCL (8 pat.), Richter transformation and high grade B cell lymphoma (1 pat. each). Median age was 72,4 years (range: 61-84) with an IPI 3-5 in 70% of patients. The main cardiac risk factor in all patients was known clinical CHF with a median left ventricular ejection fraction (LVEF) of 37% (range: 25-55). Known causes were ischemic heart disease in 5 patients. Three patients had exposure to anthracyclines in prior cancer treatment.
Results: Eight patients received four to six cycles of R-CPOP. Among those, treatment was well tolerated with hematological toxocities as expected in this patient cohort and no deaths due to neutropenic complications. No one experienced higher grade acute cardiac toxicity during treatment. Two patients did not complete the treatment, one with an initial LVEF of 25% experienced a deterioration of the CHF after the first cycle, the other with Richter transformation showed an early disease progress. While treatment is still ongoing, all of the remaining patients responded to R-CPOP with confirmed complete remission in 5 (62%) patients. This results in a median overall survival of 10 months (range: 2-31 months) so far.
Summary/Conclusion: In conclusion, using pixantrone in a first line combined R-CPOP treatment protocol for aggressive B cell NHL is feasible. An ongoing study (DRKS-ID: DRKS00000718) is active in recruiting patients and will further explore duration of response and incidence of longterm toxicity of this approach.

PB1779

PLEURAL EFFUSION IN PATIENTS WITH NON-HODGKIN LYMPHOMA

A. Roque[1,2,*], M.C. Afonso[1], M. Gomes[1], M.L. Ribeiro[1]

[1]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra, [2]Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Pleural effusion (PE) is reported in up to 20% of patients (pts) with non-Hodgkin lymphoma (NHL), and it is mainly due to pleural infiltration or lymphatic and thoracic duct obstruction. However, the risk factors for its development, as well as the evaluation of the diagnostic tools for lymphoma cells identification are not yet well established.
Aims: We aimed to evaluate the risk factors and diagnostic techniques for PE study in pts with NHL.
Methods: We analyzed all pts that performed a diagnostic thoracentesis and had a previous or simultaneous diagnosis of NHL, between January/2007 and December/2017. Inter-technique reliability was evaluated using the Cohen's kappa test. The overall survival (OS) between the groups was compared using a log-rank test, followed by subset analysis for estimated survival among patients using univariate Cox proportional hazard regression.
Results: During this period, we identified 55 pts with a median age of 76 years (26-89), 49.1% were males. The main NHL subtypes were diffuse large cell lymphoma (DLCL) (39.6%; n=21), follicular lymphoma (28.3%; n=15), chronic lymphocytic leukemia/small lymphocytic lymphoma (9.4%; n=5), marginal zone lymphoma (7.6%; n=4) and T-cell NHLs (5.7%; n=3). All the pts had stages III-IV. At the time of PE identification, 79.3% of pts (n=42) had mediastinal lymphadenopathies (28.6% bulky mediastinal disease) and 11.3% (n=6) were in leukemic form. 51.5% (n=31) pts had PE at presentation of NHL. Among those that developed PE later, during the course of the disease, the median time to diagnosis was 18.4 months; 20 had been treated with chemotherapy and 3 pts received mediastinal radiotherapy. In 17.0% of the pts the PE was bilateral; 37.7% had a chest tube drainage and only 13.2% had performed a pleurodesis. Considering PE biochemical characteristics, 84.9% pts (n=45) presented an exudate (79.2% with ≥2 Light's Criteria), 9.4% (n=5) a chylothorax and 5.7% (n=3) a transudate. Curiously, the presence of bulky mediastinal disease was not associated with the risk to develop chylothorax (OR 1.9; p=NS). The flow cytometry study was performed in 75.5% (n=40) pts and was positive in 80.5% (median effusion cellularity 3200 cells/uL; median infiltration by NHL cells 33%). NHL subtype was identified in PE in 75% of the cases. Cytology recognized abnormal cells in 42.6% pts. The consistency between flow cytometry and cytology to evaluate the presence of lymphoma cells in PE was moderate (κ=0.42). Effusion relapse occurred in 20.8% (n=11) pts, with a median time of 3.7 months. The identification of lymphoma cells in immunophenotyping (OR 2.6; p=NS) or morphological (OR 4.8; p=NS) studies did not modify the risk for relapse. Only 2 pts had bacterial growth in effusion cultures. However, although no pt had positive cultures for *Mycobacterium spp.*, 49.1% had increased levels of pleural adenosine deaminase (ADA) (>40 IU/L). The median OS for the cohort was 3.7 months. There was no difference in OS between pts with positive effusion flow cytometry (HR 1.5; p=NS) or cytology (HR 1.5; p=NS).
Summary/Conclusion: Our study shows a higher sensitivity in the identification of lymphoma cells in PEs by flow cytometry compared with cytology, with a moderate concordance between the two techniques. Pleural ADA levels had shown low specificity for tuberculosis pleuritic infection in NHL pts, suggesting that cultures for *Mycobacterium spp.* should always be performed. The presence of lymphoma cells in PE of NHL pts does not seem to have a prognostic relevance in OS.

PB1780

CIRCULATING EXSOMAL MIR-451A FOR THERAPY RESPONSE MONITORING IN DIFFUSE LARGE B CELL LYMPHOMA

C. Xu*, D. Cao, Y. Jiang, J. Xu, Y. Feng, C. Jing

West China Hospital of Sichuan University, CHENGDU, China

Background: Emerging evidence have indicated that Exosomal microRNAs(miRNAs) in serum could be used as noninvasive biomarkers for tumor early diagnosis and/or prognosis. Here we hypothesized circulating exosomal miRNA can work as a candidate for diffuse large B cell lymphoma (DLBCL) diagnosis.
Aims: To investigate the expression level and significances of therapy monitoring of circulating exsomal miR-451a in diffuse large B cell patients.
Methods: We isolated exsomal RNAs fractions from serum of DLBCL patients before treatment during treatment and after treatment, the serum of healthy controls was collected at the same time. Real time polymerase

chain reaction RT-PCR were performed to detected the expression level of circulating exsomal miR-451a.
Results: A total of 112 participates, including 56 DLBCL patients and 56 healthy controls were enrolled. Circulating exsomal miR-451a were down-expression in DLBCL compared with healthy controls(P<0.0001) and the area under the curve was 0.737 95%CI 0.645~0.816 . In patients who obtained remission including complete remission CR and partial remission PR , the levels of circulating exsomal miR-451a were gradually increased to healthy control. While in patients who did't get remission including stable disease SD and progression disease PD , the changes of the level without significant difference and still lower than healthy controls. The AUC was 0.867 95%CI 0.728~0.951 when compared remission group and non-remission group.
Summary/Conclusion: Circulating exsomal miR-451a are suitable for therapy response monitoring in DLBCL.

LONG-LASTING RESPONSES WITH EXTRACORPOREAL PHOTOPHERESIS FOR SÉZARY SYNDROME. SINGLE CENTER EXPERIENCE

M.M. Andrade Campos[1,2,*], S. Sanchez Ortega[3], C. Muniesa[4], N. García-Muñoz[3], L. Martinez[4], E. Domingo Domenech[5], E. De la Banda[6], F. Climent[6], A. Sureda[5], E. Gonzalez Barca[7], O. Servitje[8]

[1]Department of Hematology, Duran I Reynals Hospital, Catalan Institute of Oncology, IDIBELL, Barcelona, [2]U-752 Research gruop on Hematology and Lysosomal disorders., CIBER Enfermedades Raras, CIBERER, IISCIII, Madrid, [3]Catalan Blood and Tissue Bank, Barcelona, [4]Dermatology, Bellvitge Universitary Hospital, [5]Department of Hematology, Duran I Reynals Hospital, Catalan Institute of Oncology, IDIBELL, [6]Department of Pathology, Bellvitge Universitary Hospital, [7]Department of Hematology, Duran I Reynals Hospital, Catalan Institute of Oncology, IDIBELL. University of Barcelona, [8]Department of Dermatology, Bellvitge Universitary Hospital, Hospitalet de Llobregat, Barcelona, Spain

Background: Sézary syndrome (SS) is a rare (7.7 cases per million per year) and incurable disease, it is one of the major variants of cutaneous T-cell lymphomas (CTCL). Extracorporeal photopheresis (ECP) is a process by which peripheral blood mononuclear cells are isolated from circulation by discontinuous leukapheresis, exposed ex-vivo to pro-apoptotic doses of 8-methoxypsoralen and ultraviolet A radiation and reinfused. Nowadays is a technique used for different lymphocyte-mediated diseases, including CTCL, graft-versus-host disease and solid organ transplant rejection.
Aims: To analyze response rate and duration of response of ECP for advanced stage MF/SS.
Methods: Patients >18y.o, diagnosed with SS not previously transplanted treated and treated with ECP were consecutively included since August 2015. The ECP protocol included 2 procedures administered on 2 consecutive days at 2-weeks intervals until the procedure number 20, when an evaluation was performed (ECP20) assessing the skin (dermatological) and hematological responses according to Olsen criteria (Olsen *et al*., JCO 2011;29(18):2598-607). For complete dermatological response (CDR): 100% skin clearance, partial DR (PDR): 50-99% clearance of lesions without new tumors, stable D disease (SDD):<25% increase or<50% clearance of skin lesions, progressive D disease (PrDD) >25% increase or new tumors, for blood involvement: complete hematological response (CHR): B0, partial HR (PHR): >50% decrease in Sézary cells, progressive H disease (PrHD): move form B0 to B2 or >50% increase in blood burden with at elast 5,000 Sézary cells/microL, stable HD (SHD): fails to CHR, PHR or PrHD. In cases without response or progressive disease (PD), ECP was stopped; in cases with partial response (PR), bi-weekly ECP is continued until procedure number 30, in cases with complete response (CR), ECP continued 2 consecutive days every 4-week with progressive withdrawal in 10 procedures.
Results: 9 patients were eligible for ECP, 7 completed at least 20 procedures and were included in the analysis, 1 patient discontinued therapy due to PD after 18 ECP, and 1 patient due to a new diagnosis of a degenerative disease (lateral amyotrophic sclerosis). Among the 7 patients that could be evaluated at ECP20, 4 were males, mean age was 62 y.o (range: 36-72), and stage was IVA1in 5 and IVA2 in 2. In 4 patients, ECP was started in progression at a median time from diagnosis of 10 months (limits 1-101) (median previous lines 3), and in 3 cases was used as front-line therapy combined with prednisone, retinoids or interferon. ECP20 evaluation showed CR in 1 patient and PR in 6. Specific 20ECP responses were: PHR+SDD: 2, PHR+PDR: 2, CHR+PDR: 2, CHR+CDR: 1. After ECP20, 3 patients (1CHR+CDR, 2 CHR+PDR) continued bi-weekly ECP until procedure 30 and then were switched to the 4-week schedule, the other 4 patients continued in the 2-weeks schedule. With a median follow-up of 19 months (limits 8-25), none of the 7 patients lost their response. Median duration of response (PFS since ECP20) was 14 (limits 23-21) months. Currently 1 patient continues in CHR+CDR, 4 are in CHR+PDR and 2 in PHR+PDR. The patient in CHR+CDR stopped ECP after 34 procedures and continued free of relapse 21 months later. No mortalities neither hospitalization were registered during therapy. Fig1 shows two illustrative cases.

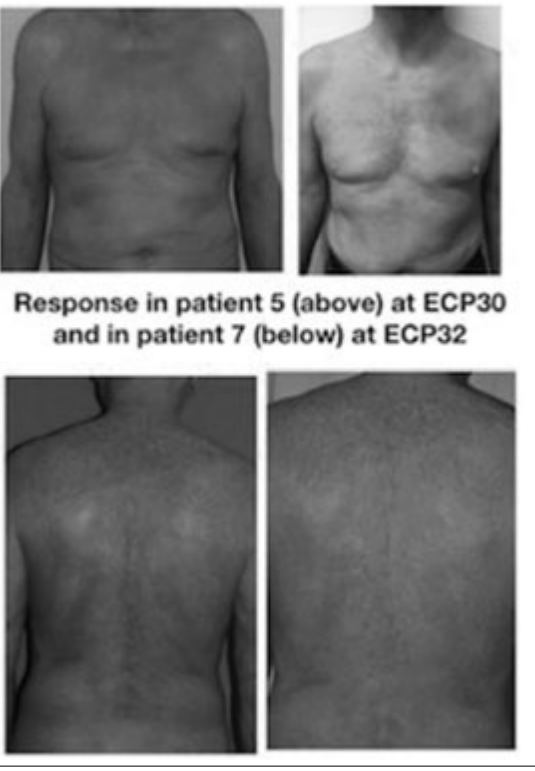

Figure 1.

Summary/Conclusion: Patients showed long-lasting responses with ECP without toxicity. Moreover, none of the responder patients at ECP20 lost their response during the follow-up.

PB1782

RISK FACTORS FOR HIGH DOSE METHOTREXATE ASSOCIATED ACUTE KIDNEY INJURY

I. Amitai[1,*], U. Rozovski[1,2], R. El-Saleh[2], P. Raanani[1,2], A. Gafter-Gvili[1,2,3], R. Gurion[1,2]

[1]institute of hematology, Davidoff Cancer Center, Rabin Medical Center, Petah-Tikva, [2]Sackler Faculty of Medicine, Tel Aviv University, Tel-Aviv, [3]Internal Medicine A, Rabin medical center, israel, Petah-Tikva, Israel

Background: High-dose methotrexate (HDMTX) is an important component in the treatment protocols of certain hematological malignancies. A significant complication of this treatment is renal failure. There is paucity of data regarding the occurrence of acute kidney injury (AKI) following HDMTX in hemato-oncological patients. Herein we aimed to explore the incidence and risk factors of AKI after HDMTX therapy.
Aims: 1. explore the incidence of AKI after HDMTX administration. 2. define the putative patients' baseline characteristics that predict the occurrence of AKI.
Methods: This is a single center, retrospective study. We reviewed the medical records of all consecutive patients who received a total MTX dose of 1500 mg or more. For these patients we collected demographic, clinical and outcome data. Acute kidney injury (AKI) was defined according to Acute Kidney Injury Network (AKIN) criteria (an increase in serum creatinine of at least 0.3 mg/dL). We compared patients with or without renal toxicity. For categorical variables, we used the χ^2 test. We used a logistic regression model with the exp(β) as an estimator of the odds ratio and the confidence interval around it in order to define which baseline variables, predict renal toxicity. We used receiver operator characteristics (ROC) curves and the area under the curve to define the best cutoff for continuous variables. The probability of overall survival (OS) was estimated by the Kaplan-Meier method. The log-rank test was used to compare survival distributions.
Results: Between January 2012 and December 2016, 136 patients received

at least one course of HDMTX in our Institute. Indications for HDMTX included: primary CNS lymphoma (n=12, 9%), other types of lymphoma (including as primary prophylaxis) (n= 96, 70%), acute lymphatic leukemia (n=24, 18%) or for various other diagnoses (n=4, 3%). The median age at diagnosis was 58 years (range 22 to 84), and 68 were males (50%). The vast majority were of good functional status, and 46 (34%) had at least one major comorbidity: vascular (n=18, 13%), diabetes (n=23, 17%) or prior malignancy (n=9, 7%). The median number of cycles per patient was 2 (range 1 to 10) and the median dose of MTX adjusted to body surface area (BSA) was 1670 mg/m^2 (range: 743 to 3865). The median time until MTX clearance was 5 days (range 3 to 20). During this time AKI developed in 12% of patients (n=16). In a univariate analysis for prediction of acute nephrotoxicity: age above 58 years (p=0.03), LDH above 470 units/L (p=0.02), MTX dose adjusted for BSA above 1640 mg/m^2 (p=0.015) and low levels of albumin at baseline (p=0.04) predicted acute MTX associated renal toxicity. In a multivariable analysis only age above 58 years remained predictive (Odds Ratio 4.6, 95% confidence interval 1.16-18.4). In 80% of cases, the creatinine levels returned to normal within 1 month. Yet, the median survival of patients who developed acute toxicity was only 38 months, while it was not reached in patients who maintained normal kidney function (Log rank= 0.06).

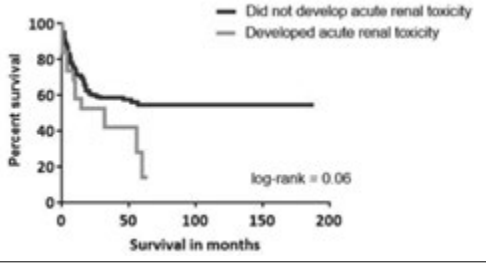

Figure 1.

Summary/Conclusion: Older age is the strongest risk factor which predicts AKI in patients receiving HDMTX. While the rise in creatinine levels is usually reversible, AKI was associated with increased mortality rates. Whether decreasing the MTX doses in the elderly population will improve outcome in these patients warrants further investigation.

PB1783

CLINICAL IMPACT OF PROGNOSTIC NUTRITIONAL INDEX IN DIFFUSE LARGE B-CELL LYMPHOMA

G.-W. Lee[1,*], S.-I. Go[1]

[1]Hematology and Oncology, Gyeongsang National University Hospital Gyeongsang National University College of Medicine, Jinju, Korea, Republic Of

Background: Cachexia is an indicator of tumor progression in patients with malignancy. Cachectic patients are intolerant to cytotoxic chemotherapy, exhibit a reduced response to antitumor therapy, and have an unfavorable prognosis. An international consensus proposed diagnostic criteria for cancer cachexia including weight loss, low body mass index (BMI), and/or presence of sarcopenia. Other potential biomarkers (e.g., albumin, C-reactive protein, pro-inflammatory cytokines, and microRNAs) and scoring systems (e.g., cachexia score [CASCO], Glasgow prognostic score [GPS], prognostic nutritional index [PNI]) have also been studied to diagnose cancer cachexia and assess its severity.
Aims: We evaluated the association between the prognostic nutritional index (PNI) and the clinical features of diffuse large B-cell lymphoma (DLBCL) and developed a novel prognostic model using a nomogram including the PNI and other biomarkers for cancer cachexia.
Methods: PNI was positively correlated with skeletal muscle index, body mass index, and serum levels of albumin. The low PNI group had a lower complete response rate (60.3% *vs* 87.6%), increased treatment-related toxicity, and more frequent treatment discontinuation (43.5% *vs* 8.8%) than the high PNI group. The median OS was shorter in the low PNI group than the high PNI group (15.6 months *vs* not reached; p<0.001). Multivariate Cox regression analyses showed that PNI, sarcopenia, and the international prognostic index (IPI) were independent prognostic factors for OS. The nomogram developed using this regression model showed excellent discriminatory ability for predicting OS (c-index, 0.80) compared to the IPI alone (c-index, 0.75).
Results: PNI was positively correlated with skeletal muscle index, body mass index, and serum levels of albumin. The low PNI group had a lower complete response rate (60.3% *vs* 87.6%), increased treatment-related toxicity, and more frequent treatment discontinuation (43.5% *vs* 8.8%) than the high PNI group. The median OS was shorter in the low PNI group than the high PNI group (15.6 months *vs* not reached; p<0.001). Multivariate Cox regression analyses showed that PNI, sarcopenia, and the international prognostic index (IPI) were independent prognostic factors for OS. The nomogram developed using this regression model showed excellent discriminatory ability for predicting OS (c-index, 0.80) compared to the IPI alone (c-index, 0.75).
Summary/Conclusion: Low PNI was associated with adverse clinical features in patients with DLBCL. The proposed nomogram supports the clinical impact of cachexia on survival and may contribute to individualized therapy in patients with DLBCL.

PB1784

RESULT OF TREATMENT OF PRIMARY LYMPHOMAS OF THE BRAIN

A. Jazyltayeva*, R. Karakulov, S. Gabbasova, E. Ishkinin, G. Sagindykov, B. Nassipov, N. Kemelbekov, A. Akanov

Hemoblostosis, Kazakh Scientific Research Institute of Oncology and Radiology, Almaty, Kazakhstan

Background: Primary non-Hodgkin's lymphomas occur in 3% of all brain tumors. This is a rare aggressive form of non-Hodgkin's lymphoma, localized in the brain, in the cerebral membranes, the spinal cord, in the orbit of the eyes.
Aims: The aim of the study is to evaluate five year overall and disease-free survival of patients with primary CNS lymphomas depending on the risk factors.
Methods: It is retrospective study of the 45 patients with primary lymphoma of the central nervous system (CNS) treated at the Kazakh Institute of Oncology and Radiology, from June 2006 to September 2016. The histological variants of the disease are presented in the form of diffuse large B-cell lymphoma in 28 patients, in the B-cell unspecified lymphoma in 16 patients, in the marginal zone-one patient. Mean age 48.4 (21-66). Women-24 (53.3%), men-21 (46.7%). Local forms-15 (33,3%), advance forms-30 (66,7%) of CNS lesion. The increase in LDH was registered in 32 patients. All patients received 3 cycles of chemotherapy (methotrexate 3.5 mg / m^2 1d, cytarabine 2 g / m^2 twice a day 2+3 d) with an interval of 21 days, following whole brain radiotherapy and for patients with PR adding boost for residual tumor.
Results: Complete response (CR) was achieved-28 (62.2%), partial response (PR) -16 (35.5%), progressive disease (PD) -one (2.2%). The OS for all patients 48.9%, median was 21.6 months, SE 17.4, CI 95% (0-55.6). Patient performance status assessed by Karnovskiy scale before treatment 63.3, in the end of treatment 72.7. The recurrences of the disease were registered 21 patients (46.7%), the majority of patients were included in the unfavorable group on the Extranodal Lymphoma Study Group scale. Seventeen patients had a local recurrence, two-spinal cord recurrence. Recurrence-free median 24.6, SE 5.5, CI 95% (13.8-35.3). According to the Extranodal Lymphoma Study Group scale we have analyzed risks factors such as age, tumor lesion. It was presented that in the group of age >50, OS 46.4%, median was 31.5 months, SE 4.2, CI 95% (23.4-39.7). Age<50 OS 52.9%, median was 37.5 months, SE 10.8, CI 95% (16.3-58.7). For age risk factor differences not significant (χ2=0,2 p=0,65). Recurrence for older than 50 years, and younger was 42.9% and 52.9% respectively, differences not significant (χ2=0,16 p=0,69). In the local forms, OS 66.7%, median was not achieved yet. In that time advance forms OS 40.0%, median was 15.7 months, SE 5.3, CI 95% (5.3-26.0). For dissemination risk factor differences significant (χ2=5,2 p=0,02). Recurrence for local and advance forms was 40% and 50% respectively, differences not significant (χ2=0,9 p=0,34). Infectious complications were diagnosed in seven patients. Neurological toxicity was observed in 12 patients, in the form of intense headaches, aggressive behavior and sleep disturbances after radiation therapy.
Summary/Conclusion: The analysis of the results obtained during chemotherapy for patients with primary CNS lymphoma, according to the prognostic factors (prevalence of the process, age), showed that relapses of the disease were more frequent in the group with unfavorable prognostic risk factors, the overall survival of patients in this group was lower than in a group with a favorable prognosis.

PB1785

VEINO-OCCLUSIVE DISEASE (VOD) DURING AUTOLOGOUS STEM CELL TRANSPLANTATION (ASCT): WARNING ABOUT SUSPECTED INCREASED INCIDENCE AFTER OXALIPLATIN-CONTAINING SALVAGE REGIMEN

P.-E. Debureaux[1,*], D. Le Febvre de Nailly[2], K. Belhadj[1], F. Le Bras[1], L. Roulin[1], C. Salvado[1], T. El Gnaoui[1], M. Hammoud[1], F. Lemonnier[1,3], D. Azoulay[3,4], J.P. Richardet[5], A. Luciani[3,6], S. Mulé[6], J. Calderaro[7], M. Carvalho[2], C. Haioun[1,3], J. Dupuis[1]

[1]Lymphoid Malignancies Unit, [2]Pharmacy Unit, Henri Mondor University Hospital,

[3]Paris Est-Créteil University (UPEC), [4]Department of Hepatobiliary and Pancreatic Surgery and Liver Transplantation, [5]Departement of Hepatology and Gastro-Enterology, [6]Department of Radiology and Medical Imaging, [7]Department of Pathology, Henri Mondor University Hospital, Créteil, France

Background: ASCT is a cornerstone in lymphoma therapeutics, especially in the relapse setting. BEAM (Carmustine, Etoposide, Cytarabine and Melphalan) conditioning regimen is the most widely used with a low toxic mortality rate. Bendamustine has been occasionally used as a substitute for Carmustine ("BendaEAM") during shortage periods. VOD is a potentially life-threatening complication, rarely observed after ASCT.
Aims: During the last 2 years, we observed 5 cases in patients treated with BEAM or BendaEAM in our department. Two patients required hepatic transplantation (HT).
Methods: We recorded cases of VOD observed in our department after ASCT. The new EBMT classification for VOD was used [1].

Table 1.

Age at ASCT/Sex	Type of lymphoma	First line	Second line / Third line	Risk factor of VOD before ASCT	Conditionning	VOD Grade	Delay ASCT-VOD	Treatment	Post ASCT Outcomes (months)
Five cases in Mondor between 2015 and 2018: DHAOX followed by ASCT									
44/F	MCL	R-DHAOx	None	Hydroxyurea, SGOT at 1.5 ULN	BEAM	Moderate	5	Support	Alive at 19m
58/M	FL	Mini-CVP+Rtx	BR+Rtx / R-DHAOx	None	Benda-EAM	Moderate	5	Defibrotide	Alive at 18m
62/M	DLBCL	R-CHOP21	R-DHAOx+Ibrutinib	Metabolic syndrom, Carmustin 80%	BEAM	Very severe	8	Defibrotide+HT	Dead at 1.5m
58/F	FL	R-CHOP21+ Rtx	R-DHAOx	None	Benda-EAM	Very severe	5	Defibrotide+HT	Alive at 29m
63/M	MCL	CALGB+DHAOx	None	Carmustin 80%	CALGB-BEAM	Severe	15	Defibrotide	Alive at 1m
Last case in Mondor in 2009									
41/F	HL	ABVD	BEACOPP	None	BEAM	Mild	12	Support	Alive at 90m

MCL : mantle cell lymphoma / FL : follicular lymphoma / DLBCL : diffuse large B-cell lymphoma / HL : Hodgkin Lymphoma
CVP : Cyclophosphamide Vincristine Prednisone / Rtx : Rituximab in abbreviation / BR : Bendamustine Rituximab / HT : Hepatic transplantation
CALGB : Chemotherapeutic / IFN : Interferon / ULN : upper limit normal

Results: Case 1: A 54 y.o. woman was diagnosed in 2010 with grade I-II follicular lymphoma. Complete remission (CR) was obtained after 6 cycles of R-CHOP21 and 2 years of Rituximab maintenance. Upon relapse in March 2015, a second CR was obtained after 4 cycles of R-DHAOX (Rituximab, Dexamethasone, High-dose Cytarabine, Oxaliplatin) delivered every 3 weeks [2]. ASCT was performed in the setting of the "BENEFIT" study (NCT02008006) using BendaEAM with Bendamustine 200 mg/m². VOD started at day 5 with ascites, painful hepatomegaly, weight gain (11%) and jaundice. Factor V dropped and hepatic encephalopathy occurred. At day 15, HT permitted recovery. At 29 months of follow-up, she is in persisting CR and didn't present any major complication of HT.Case 2: A 60 y.o. man was diagnosed in 2015 of diffuse large B-cell lymphoma treated by 8 cycles of R-CHOP. In May 2017, relapse occurred. Second CR was obtained with 3 cycles of R-DHAOX + Ibrutinib in the setting of the "BIBLOS" study (NCT02055924) followed by BEAM/ASCT. VOD started at day 8 with ascites, tender hepatomegaly, weight gain (8%) and jaundice. Low factor V and encephalopathy led the patient to receive an HT at day 12. After transient improvement, he died of septic choc. The same pattern was observed in 5 cases of VOD in last 3 years : R-DHAOx inductive salvage regimen followed by consolidative ASCT (conditioning by BEAM or BendaEAM). The last case before this period was a woman in 2009 who presented mild VOD after BEACOPP and BEAM/ASCT. Characteristics of these patients are described in table 1. None had major comorbidities. Between 2008 and 2017, incidence of VOD in our department following DHAOX/ASCT was 6.4% (5/78) *versus* 1.3% (1/75) after other salvage regimen/ASCT for lymphoma.
Summary/Conclusion: In the last decade, Cisplatin was often replaced by Oxaliplatin in the DHAP protocol in order to avoid renal impairment. Preoperative Oxaliplatin in hepatic metastatic of colorectal cancer leads to asymptomatic sinusoidal damage in half of patients and could explain the increase of VOD in ASCT [3]. We need to be more aware of risk in this setting and national report is ongoing. Management of VOD could include HT with limits about status of disease and multi-organ failure.

PROGNOSTIC FACTORS AND TREATMENT OUTCOMES IN PATIENTS WITH PERIPHERAL T-CELL LYMPHOMAS-A SINGLE CENTRE EXPERIENCE

T. Skrypets[1,*], O. Novosad[1], I. Pastushenko[1], T. Kadnikova[1], I. Tytorenko[1], O. Aleksik[1], Y. Stepanishina[1], K. Filonenko[1], A. Martynchyk[1], K. Ulianchenko[1], E. Kushchevyy[1], O. Gorbach[2], I. Kriachok[1]

[1]Oncohematology, [2]Experimental Oncology, National Cancer Institute, Kiev, Ukraine

Background: Peripheral T-cell lymphomas (PTCLs) are a rare heterogeneous group of lymphoid malignancies (5-15% of all non-Hodgkin lymphomas) with aggressive clinical behavior. There are three most common subtypes of PTCLs: Peripheral T-Cell Lymphoma (NOS), ALCL and AICL. Compared to B-cell lymphomas, which incidence remains stable, level of T-cell lymphomas have been rising continuously. Despite worldwide standard of first-line treatment, using anthracycline-based regimens, there is a need for better management of this patients. Unfortunately, due to lack of cases and randomized clinical trials, there are still inconsistency of specific prognostic factors in PTCLs.
Aims: The primary endpoint was event-free survival (EFS) and overall survival (OS), depending on PTCL type. We evaluated the influence on patients outcomes of different prognostic factors, which are included in PTCLs prognostic scores (IPI, IPTCL, PIT, mPIT).
Methods: We analyzed 50 patients (median age: 57, range: 22-80 years; males: 34, females: 16) with PTCLs treated from Sep 2006 to Feb 2018 in NCI (Kiev, Ukraine). Twenty two patients (44%) have PTCL (NOS), ALK –ve were 11 (22%) pts, ALK +ve-11 (22%) pts and 6 (12%) have unknown ALK status. 82% and 18% pts were younger and older than 65 y.o, respectively. They were assessed with IPI, IPTCLP, PIT and mPIT prognostic scores. Patients received CHOP-like chemotherapy regimens (CHOP, CHOEP, EPOCH).
Results: ORR was observed in 66% cases, progression on therapy had 34% pts. We registered 48% of relapses after the 1-st line therapy during the follow-up period (median-11 months; range 1–85 months). EFS was associated with LDH level (>620 U/l) and stage (III-IV) by ROC analysis [Sp=64.71%, Se=82.35%, AUC= 0.74, p=0,0011] and [Sp=66.67%, Se=65.38%, AUC= 0.66, p=0,03], respectively. 3-year EFS showed worse outcomes in pts with high LDH level 25% *vs* 75% in pts with normal LDH (p<0.05). Patients with stage I-II had better 3-years EFS compared to stage III-IV, 62% *vs* 15%, respectively (p<0.05). Also, multivariate analysis revealed that ECOG influence on EFS with HRs of 3.3 [95% CI 1.16–9.5, p=0.001]. The 3-year EFS in patients with ECOG<1 was 50% *vs* 15% with ECOG >1. Any significant difference was found between bone marrow involvement, age, gender, B-symptoms, Ki-67, albumin, ANC, platelets level and EFS rate. Also, there was no superiority between conventional CHOP *vs* more intensive CHOEP ana EPOCH (p=0.16). 5-year OS was 33%, 45% and 90% in PTCL (NOS), ALK –ve and ALK +ve, respectively (p<0.05).
Summary/Conclusion: PTCLs are still remaining a rare group of lymphoid malignancies, which are difficult to cure. Over the last decades, several studies showed prognostic evaluation in clinical and pathologic features of PTCLs. In our retrospective analyses we identified LDH level (>620 U/l), stage (III-IV) and ECOG >1, as the most valuable factors that predict a lower level of EFS in patients with PTCL (NOS), ALK –ve, ALK +ve lymphomas.

PB1787

PROGNOSTIC IMPACT OF PRETREATMENT ALBUMIN TO GLOBULIN RATIO IN ELDERLY PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH R-CHOP

S.-H. Kim[1,*], G.-W. Lee[2]

[1]Division of Hematology and Medical Oncology, Department of Internal Medicine, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon, [2]Division of Hematology-Oncology, Department of Internal Medicine, Gyeongsang National University School of Medicine, Jinju, Korea, Republic Of

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin lymphoma, representing about 30% of cases. The introduction of rituximab (R) in combination with CHOP (cyclophosphamide, doxorubicin, vincristine, and prednisolone) chemotherapy, usually also known as 'R-CHOP,' improved survival outcomes, and has affected the importance of formerly recognized prognostic markers. In the pre-R era, the International Prognostic Index (IPI) was usually used to predict responses and prognoses in patients with high-risk non-Hodgkin's lymphoma, but in the post-R era, the original IPI could not well identify a poor prognostic group with under half risk for survival.
Aims: We evaluated the clinical implication of the albumin to globulin ratio (AGR) in patients with diffuse large B-cell lymphoma (DLBCL) treated with rituximab, cyclophosphamide, doxorubicin, vincristine, and prednisolone (R-CHOP).
Methods: Data for 232 DLBCL patients treated with first-line R-CHOP from 2004 to 2017 were reviewed retrospectively. Patients with AGR ≥1.22

and<1.22 were assigned to the high and low AGR groups, respectively. Treatment response and survival were compared according to AGR.
Results: The low AGR group (median overall survival [OS]=26.87months; 95% confidence interval[CI]=4.19-49.55) showed a significant decrease in OS compared to the high AGR group (median OS=148.83months;95% CI=76.26-221.41;*p*<0.001). Progression-free survival (PFS) was also significantly decreased in the low AGR group (median PFS=14.29months; 95% CI=2.58-26.01) compared to the high AGR group (median PFS=148.83months; 95% CI=76.21-221.45; *p*<0.001). However, in a multivariate analysis, low AGR was an independent poor prognostic factor for OS (hazard ratio [HR]=0.55; 95% CI=0.35-0.86; *p*=0.008) and PFS(HR=0.54;95% CI=0.35-0.83; *p*=0.005) only in elderly.
Summary/Conclusion: Pretreatment AGR can be useful for predicting clinical outcomes and prognosis in elderly patients with DLBCL treated with R-CHOP. Further large prospective studies will be necessary to validate our findings.

PB1788

THE FREQUENCY AND CLINICAL FEATURES OF DOUBLE-HIT DIFFUSE LARGE B-CELL LYMPHOMA-THE EXPERIENCE OF A SINGLE INSTITUTE IN TAIWAN

Y.-C. Su[1,2,*], C.-H. Lee[3], Y.-K. Lin[4], S.-M. Hsieh[5], M.-L. Liu[5], T.-Y. Chao[2], J. Whang-peng[6], Y.-Y. Hsieh[2], W.-H. Cheng[2]

[1]The PhD Program for Cancer Biology and Drug Discovery, College of Medical Science and Technology, Taipei Medical University, Taipei, [2]Hematology-oncology, Taipei Medical University-Shuang Ho Hospital, New Taipei, [3]Pathology, Taipei City Hospital Heping Fuyou Branch, [4]Research Center of Biostatistics, College of Management, Taipei Medical University, Taipei, [5]Pathology, Taipei Medical University-Shuang Ho Hospital, New Taipei, [6]Cancer Center, Wan Fang Hospital, Taipei, Taiwan, Republic of China

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common subtype of non-Hodgkin's lymphoma and it accounts for about half of all lymphomas in Taiwan. The gene expression profiles (GEP) may confer some clues for clinicians to predict the prognosis. According to the GEP, DLBCL can be divided into 3 subtypes: germinal center type, activated B-cell type and type III. The germinal center B-cell (GCB) phenotype of DLBCL usually results in a good prognosis with a 5-year overall survival (OS) of 59%, while the 5-year OS of activated B-cell (ABC) phenotype is poor (about 31%). Recent studies showed DLBCL with concurrent translocation of Myc and BCL2/BCL6 (double hits), the so-called double-hit lymphoma (DHL) may have a dismal prognosis in spite of the GCB phenotype.The previous studies showed concurrent BCL2 and Myc translocations account for about 75% of DHL while BCL6 translocated DHL is less 25%. However,we did not have any data about the frequency and clinical features of DHL in Taiwan.
Aims: We would like to understand the frequency of double hits in patients with DLBCL in Taiwan and figure out their clinical features.
Methods: We retrieved 88 patients with newly-diagnosed DLBCL in the Shuang-Ho Hospital from 2009 to 2016. The translocations of Myc, BCL2 and BCL6 were detected by the fluorescence in-situ hybridization (FISH), using the break-apart probes of target genes. We tested all samples with the Myc probe first and both BCL2 and BCL6 translocations would be screened for samples with positive Myc translocation.
Results: Among 88 DLBCL patients, we found 15 patients with Myc translocation, accounting for 17% of all DLBCL patients. Meanwhile, there were 9 patients with concurrent Myc and BCL2/BCL6 translocations, account for 10.2% (Figure 1A). Among them, two-thirds (6 patients) were BCL6-translocated while the others (3 patients) had BCL2 translocation(Figure 1B). This finding was quite different from the results of prior reports in which BCL2 translocation accounted for the majority of the double-hit lymphoma. The median age of patients with DHL was 62 years(Table 1). In addition, the DHL group had a high ratio of advanced disease (88.9%), indicating a more extensive involvement at presentation. Meanwhile, the male gender was predominant in the DHL group (77.8%). Phenotype could not be identified in 1 BCL2-translocated patient because of lack of the residual sample. The others in this group were exclusively GCB phenotype. In contrast, two-thirds of BCL6-translocated DHL patients had non-GCB DLBCL. This result caused our attention because the majority of DHL patients were GCB phenotype in the prior reports. In our cohort, the median OS of DHL patients was 344 days, compatible with results of previous studies, while that of the non-DH DLBCL patients were 574 days (Figure 2). It seemed that the DHL patients survived worse than its non-DH counterpart. In spite of this, there was no significant difference between these 2 groups in OS and the major factor was probably the small sample size of the DHL group.

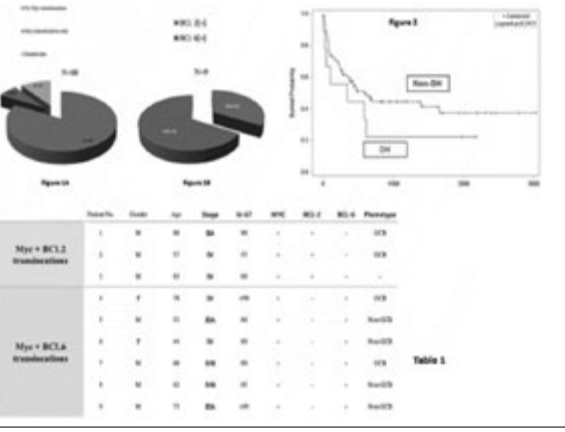

Figure 1.

Summary/Conclusion: The frequency of DHL in our institute was 10.2% and the majority of DHL were BCL6-translocated with an advanced disease(88.9%). The DHL patients seemed to have a worse prognosis than non-translocated ones without a clinical significance.

PB1789

OXIDATIVE STRESS EVALUATION IN DIFFUSE LARGE B-CELL LYMPHOMA

M.-A. Gaman[1,*], A.M. Gaman[2,3]

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Pathophysiology, University of Medicine and Pharmacy of Craiova, [3]Hematology, Filantropia City Hospital of Craiova, Craiova, Romania

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive form of Non-Hodgkin's lymphoma (NHL) which can occur *de novo* or by transformation of a less aggressive NHL of B-cell origin such as follicular lymphoma (FL). The genesis of lymphoma has yet to be explained. Several studies have suggested that oxidative stress, via chronic inflammation, might play a role in DLBCL, since its involvement has been shown in aging and in many hematological disorders[1-8].
Aims: The major aim of this study is to evaluate the levels of reactive oxygen species and the total antioxidant capacity in patients with DLBCL compared to healthy controls before and after R-CHOP therapy. The minor aim is to observe if the level of HDL-cholesterol was related to the oxidative status of the study group.
Methods: We enrolled 32 Romanian patients with DLBCL and 20 healthy controls. Informed consent was obtained from all subjects involved. The positive diagnosis was based on lymph node biopsy with histopathological and immunohistochemical examination. The Ann-Arbor staging system was used for staging. The standard treatment consisted of 6-8 cycles of R-CHOP. Oxidative stress was evaluated at diagnosis and at the end of therapy using a CR3000 analyzer from a single drop of capillary blood. Reactive oxygen species were evaluated by FORT (Free Oxygen Radicals Testing) and the total antioxidant capacity by the FORD (Free Oxygen Radicals Defense) assays. The normal ranges for the assays are: FORT<2.3 mmol/L H_2O_2 and FORD=1.07-1.53 mmol/L. HDL-cholesterol was also evaluated. Statistical data analysis was performed using the student T-test and a p-value ≤0.05 was considered significant.

Table 1.

Stage	HDL [mg/dL]	FORT [mmol/L H_2O_2]	FORD [mmol/L]	Evaluation
IIB	67	2.5	1	At diagnosis
IIB	78	1.1	1.5	After treatment
IIIB	47.5	3.1	0.6	At diagnosis
IIIB	66	1.7	1.4	After treatment
IVB	32.5	3.6	0.3	At diagnosis
IVB	53.8	2.4	1	After treatment
Study group	47	3.1	0.6	At diagnosis
Study group	65	1.8	1.3	After treatment

Results: The study group had the following characteristics: median age=52.0 years, 62.5% males, 37.5% females, 75% patients from urban areas, 25% patients from rural areas, 93.75% *de novo* DLBCL cases, 6.25% cases transformed from FL. The control group had a median age=64.1±2.26 years. DLBCL staging revealed: stage IIB=5 cases, stage IIIB=19 cases and stage IVB=8 cases. The evolution was favorable with complete remission in 24 cases, 6 patients had partial remission after conventional treatment, and 2 patients had refractory disease. Before treatment, HDL-cholesterol value was normal (>60 mg/dL) in 9 patients (5 in stage IIB and 4 stage IIIB) and low in 23 patients. The results of oxidative status evaluation and HDL-cholesterol are depicted as mean values in the attached table. After treatment, FORD and HDL-cholesterol values significantly increased, whereas FORT values significantly decreased ($p \leq 0.05$), with the exception of the 2 cases of refractory DLBCL.
Summary/Conclusion: We found an unbalanced oxidative status in DLBCL patients compared to controls: FORT levels were increased, whereas FORD and HDL-cholesterol levels were decreased. FORT levels decreased, whereas FORD and HDL-cholesterol values increased after chemotherapy regimens. Further comprehensive studies must be performed to highlight the involvement of oxidative stress in DLBCL.

IMMUNOGLOBULINOPATHIES IN PATIENTS WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

N. Chernova[1,*], N. Soboleva[2], S. Maryna[2], Y. Sidorova[3], M. Sinitcina[4], V. Dvirnyk[2], E. Zvonkov[1]

[1]Department Chemotherapy of Lymphomas, [2]Clinical Diagnostic Laboratory, [3]Department of Molecular Hematology, [4]Department of Pathology, National Research Center for Hematology, Moscow, Russian Federation

Background: Angioimmunoblastic T-cell lymphoma (AITL) is a rare form of non-Hodgkins lymphoma, characterized by generalized lymphadenopathy, hepatosplenomegaly and dysproteinemia. Hypergammaglobulinaemia is revealed in 50–83% pts with AITL. However, the characteristics of immunoglobulinopathies observed in AITL are scarce.
Aims: The aim of the study was to characterize quantitative and qualitative immunoglobulinopathies in patients with AITL at the onset of the disease.
Methods: 55 patients with newly diagnosed AITL were enrolled in the study, the male/female ratio was 30/25; median age was 61 (29-81) years. Diagnosis was based on standard WHO criteria. Immunochemical studies of blood serum included serum protein electrophoresis/immunofixation, nephelometric quantification of total immunoglobulins, serum free light chain assay.
Results: Quantitative and qualitative immunoglobulinopathies were determined in 49 (89,1%) of 55 pts. Quantitative immunoglobulinopathies were revealed in 47 (85.5%) of 55 cases, qualitative-in 14 (25,5%). Combination quantitative and qualitative immunoglobulinopathies was observed in 12 (21,8%) of 55 pts. The detected immunoglobulinopathies were divided into 4 groups: polyclonal hypergammaglobulinaemia, hypogammaglobulinaemia, oligoclonal gammapathy, and monoclonal gammapathy. Polyclonal hypergammaglobulinaemia was marked in 41 (74.5%) of 55 pts, elevated level of IgG was determined in 27 (49,15%) of 55 cases, IgM-in 18 (32,7%) and IgA-in 21 (38.2%). Interestingly, polyclonal IgE hypergammaglobulinaemia was detected in 12 (48,0%) of 25 cases of performed studies. Simultaneous increase of serum level of *3 immunoglobulin classes* was observed in 8 (24.2%) of 40 pts, 2 classes-in 13 (39.4%), 1-in 12 (36.4%). Hypogammaglobulinaemia was detected in 8 (14,5%) of 55 cases. Oligoclonal gammapathy was determined in 4 (7.3%) of 55 pts. Monoclonal gammapathy was revealed in 11 (20,0%) of 55 cases. The amount of monoclonal immunoglobulin varied from 2.6 to 14.1 g/l. Monoclonal immunoglobulin Gk was detected in 5 of 11 pts, Gλ-in 2, Mλ-in 2, Mk-in 2. Monoclonal gammapathy was accompanied by polyclonal hypergammaglobulinaemia in 9 of 11 cases, hypogammaglobulinaemia-in 2.
Summary/Conclusion: Quantitative and qualitative immunoglobulinopathies are observed in most patients at the onset of AITL. Quantitative abnormalities were determined more often than qualitative. Monoclonal gammapathy can be a manifestation of lymphoproliferation and other concomitant disorders. The prognostic value of immunochemical parameters is still unclear and requires dynamic observation and study.

PB1791

PRIMARY MEDIASTINAL LARGE B-CELL LYMPHOMA AND EXTRAMEDIASTINAL LESION

Y. Mangasarova*, A. Magomedova, A. Misyurina, E. Nesterova, S. Kravchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: Primary mediastinal large B-cell lymphoma (PMBCL) is derived from a thymic B-cell and commonly presents as a bulky lesion in anterior-superior mediastinum. Extramediastinal lesions is an extremely rare situation and require differential diagnostics with diffuse large B-cell lymphoma (DLBCL).
Aims: To evaluate clinical features and treatment efficacy in patients with PMBCL with extramediastinal lesion.
Methods: From 2007 to 2018 years, 157 patients were diagnosed with PMBCL (according to WHO criteria) in National Research Center for Hematology Ministry of Health, Moscow, Russian Federation. Extramediastinal involvement was detected in 16 patients, 3 of them were at different stages of pregnancy. The median age of patients was 27 (23-69) years. 8/16 patients underwent molecular analysis for determination of gene overexpression JAK2, TRAF1, MAL, PDL1, PDL2. In all 8/8 of cases, overexpression of 2 or more genes was determined, which allowed confirming and in some cases to revise diagnosis in favour of PMBCL.
Results: In 69% of cases, nonlymphoid extramediastinal lesions below diaphragm were verified, which involved internal organs. In 31% of cases, there were multiple involvements of organs. The most frequently were noted involvement of kidney-4/16 of cases, ovarian-3/16 of cases, pancreas-3/16 of cases and bone marrow-3/16 of cases (confirmed by the molecular study). Gastric involvement was revealed very rarely-1/16 of cases, an involvement of bones-1/16 of cases, soft tissues involvement-1/16 of cases. In 15 from 16 cases, an isolated extramediastinal lesion was combined with involvement of antero-superior mediastinum and only in one from 16 patients was revealed isolated thoracic soft tissues involvement (without involvement of mediastinal structures).
Summary/Conclusion: in 15/16 of PMBCL cases extramediastinal lesions were revealed in addition to anterior-superior mediastinum involvement. In 1 of 16 cases, thoracic soft tissue involvement was not accompanied by presence of a tumour in mediastinum. This clinical feature required an additional molecular study that allowed to diagnose primary mediastinal large B-cell lymphoma. Thus, in case of mediastinal tumour and presence of extramediastinal lesions in young patients differential diagnosis between primary mediastinal large B-cell lymphoma and advanced stage diffuse large B-cell lymphoma with extramediastinal lesion should be performed.

PB1792

PRIMARY CNS LYMPHOMA: SINGLE INSTITUTION EXPERIENCE WITH THE 2015 GELTAMO PROTOCOL

A. Lancharro, C. Cañigral*, J. Clavel, A. Gascon, D. Linares, R. Garcia, M. Fernandez-Delgado, L. Serrano, I. Garcia, M. Mas, I. Cuadrado, P. Carrascosa, M.B. Contreras, G. Cañigral

Hematology, Hospital General De Castellon, Castellon, Spain

Background: Primary central nervous system lymphoma (PCNSL) is an uncommon variant of non-Hodgkin lymphoma, being immunodeficiency its main predisposing factor. Without treatment, the evolution of PCNSL is rapidly fatal. Published data support the use of penetrating chemotherapy in CNS to avoid the side effects of radiotherapy. In this sense, the GELTAMO group developed in February 2015 a protocol with carmustine, rituximab, cytarabine and high dose methotrexate (BRAM) followed by high-dose chemotherapy with carmustine and thiotepa and autologous stem cell transplant rescue (ASCT).
Aims: This retrospective study aimed to analyse the characteristics and outcomes of patients diagnosed of PCNSL in our institution since the implementation of the *2015 GELTAMO* protocol.
Methods: All adult (>16 years) patients with PCNSL diagnosed in our centre from February 2015 to February 2018 were identified. Clinical, histopatho-

logical and cytogenetic data at diagnosis were collected, as well as information of treatment outcomes and toxicities.

Figure 1.

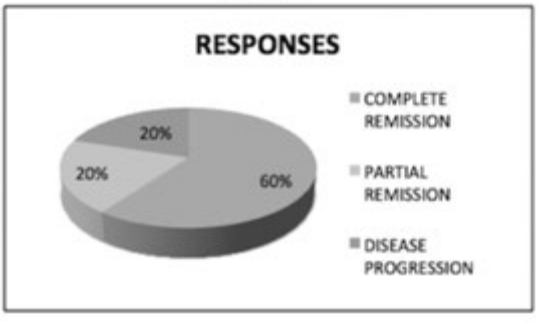

Figure 2.

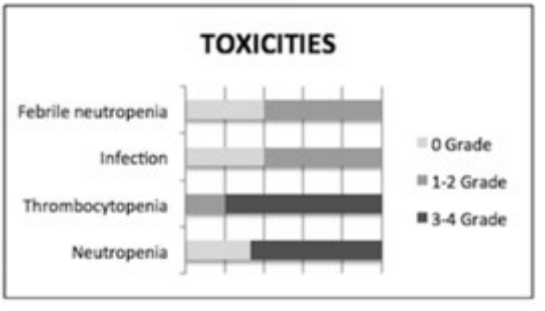

Figure 1.

Results: Between February 2015 and February 2017, 7 patients were diagnosed of PCNSL. Their clinic and histologic characteristics are shown in *table 1.* Two patients were managed by palliative care because of their age (above 74 years) and general condition (ECOG >3); they died within 6 months from diagnosis.The remaining 5 patients received 2 cycles of BRAM according to the *2015 GELTAMO* protocol.Three patients (60%) received BRAM full doses and all of them achieved complete remission.Two patients (40%) required dose reduction of methotrexate and cytarabine due to treatment related toxicities and advanced age respectively. Of these, one reached stable disease and required radiotherapy prior to ASCT and one reached complete remission and did not receive ASCT but relapsed after 4 months.Two patients (40%) did not undergo ASCT because of comorbidities, being now one in relapse and one in complete remission.Of the three patients who received ASCT (60%), two achieved complete remission and one is in now in the ASCT procedure.The responses and mayor toxicities are shown in figures 1 and 2 respectively.Toxicities were mainly hematologic, infectious and renal. They were manageable, but forced to reduce doses in one patient.Their progression free survivals are in the range of 9 to 20 months.

Table 1. Patient Characteristics (n=7).

Gender-no. (%)	
Female	2(29)
Male	5(71)

Treatment- no. (%)	
Palliative	2 (29)
BRAMx2 cycles	2 (29)
BRAMx2 cycles + autologous HCT	3(43)
Radiotherapy prior to autologous HCT	1 (14)

Summary/Conclusion: PCNSL continues to be a challenge for haematologists. Our results show that the *2015 GELTAMO* protocol is an effective and feasible treatment scheme. Toxicities were manageable, being grade 2-3 haematological toxicity the most frequent complication.The ASCT role in the duration of remission and survival should be evaluated with longer follow-up.

PB1793

AUTOLOGOUS STEM CELL TRANSPLANTATION AS FIRST-LINE TREATMENT OR SALVAGE REGIMEN FOR LARGE B-CELL LYMPHOMA IN THE RITUXIMAB ERA: A SINGLE CENTRE EXPERIENCE

M. Riva*, A. Visentin, G. Scapinello, L. Ammirati, L. Frison, A. Branca, T. Berno, C. Gurrieri, R. Zambello, L. Trentin, F. Piazza, G. Semenzato

Department of Medicine, Hematology and Clinical Immunology Unit, Padova, Padova, Italy

Background: Diffuse large B-cell lymphoma (DLBCL) is an aggressive but potentially curable B cell tumor, characterized by an extreme biological complexity and different clinical outcomes. Recent studies suggested that the use of front-line high-dose therapy (HDT) followed by autologous stem cell transplantation (ASCT) in untreated high-risk DLBCL does not improve the outcome, while this approach remains the standard of care for chemosensitive relapse/refractory (R/R) DLBCL. However, the outcome of many R/R DLBCL still remains unsatisfactory.
Aims: We analyzed the outcome and toxicities in a cohort of DLBCL patients treated with HDT and ASCT as first-line or salvage approach at our centre.
Methods: We retrospectively evaluated a group of 34 high-risk DLBCL patients, who underwent ASCT (12 as first-line and 22 as salvage regimens). Median age at diagnosis was 50 years (range 21-70 years). Adverse clinical features in the upfront HDT and R/R groups, were: Ann Arbor stage III to IV (77% *vs* 86%), ECOG ≥2 (25% *vs* 10%), bulky disease (58% *vs* 45%), ≥2 extranodal sites (25% *vs* 32%), B symptoms (67% *vs* 41%), R-IPI poor (58% *vs* 68%), CNS-IPI intermediate to high-risk (83% *vs* 86%), primary refractory/early relapse (42% *vs* 77%), cell of origin (COO as per Hans' immunohistochemistry (IHC) algorythm: GCB 33% *vs* 36% and non-GCB 42% *vs* 50%), BCL2 positivity in IHC (50% *vs* 73%), high proliferation index (Ki67 ≥70: 42% *vs* 45%). c-Myc was evaluated only in 8/34 patients (23%). Cytogenetics and FISH analysis were performed at diagnosis in 30/34 patients (88%). Results were: poor/complex karyotype (17% *vs* 23%) and double hit lymphoma (2 patients in the upfront HDT group *vs* 1 patients in the R/R group). Salvage regimens were R-DHAP, R-ICE or R-CODOX/IVAC; ASCT conditioning was BEAM (10 patients), BEAM-like (15 patients) or Mitox/L-PAM (7 patients). Response was assessed using the revised Lugano criteria.
Results: There were not significant differences in CR rate, OS and PFS between the upfront HDT and R/R group (CR: 58% *vs* 55%, p=0.9; 3-year OS: 54.5% *vs* 58.4%, p=0.9; 3-year PFS: 56.3% *vs* 59.1%, p=0.9). Grade ³3 hematological and non-hematological adverse events were reported in 58% patients in the upfront HDT group *versus* 55% patients in the R/R group. Conditioning regimens provided comparable results, both in term of toxicity and efficacy against lymphoma. Five patients (42%) in the upfront HDT group and nine patients (41%) in the R/R group died. No differences in OS and PFS were observed according to the COO, BCL2 positivity, lymphocyte/monocyte ratio at diagnosis and subdiaphragmatic disease. The presence of R-IPI poor and Ki67≥70% at diagnosis significantly impacted on OS and PFS (for R-IPI poor, 3-year OS 45%, p=0.07, 3-year PFS 46%, p=0.05; for Ki67≥70%, 3-year OS 30%, p=0.03, 3-year PFS 33%, p=0.03: data confirmed also in multivariate analysis).
Summary/Conclusion: Our analysis is a "real life" experience of treatment choices for high risk DLBCL; we confirmed that front-line HDT followed by ASCT in untreated high-risk DLBCL does not improve CR, PFS and OS, compared to ASCT in the R/R setting. Hematologic and non-hematologic toxicities were similar in the upfront HDT and R/R groups. Importantly, in our cohort an high R-IPI and elevated Ki67 positivity at diagnosis significantly impacted on OS and PFS. These markers together with other recognized prognostic factors validated in the R/R setting (as described in the CORAL study and in REFINE analysis), should be assessed to help discriminate patients in which conventional salvage therapies is not appropriate.

PB1794

DIFFUSE B CELL LYMPHOMA: AN AUDIT ON DEPARTMENTAL ADHERENCE TO BRITISH HAEMATOLOGICAL SOCIETY (BSH) GUIDELINES FOCUSING ON APPROPRIATE PROPHYLAXIS AND CHARACTERISTICS OF PATIENTS WITH HIGH MORTALITY

H. Vijayenthiran*, C. Gregory

Haematology, Wigan Royal Infirmary, Wigan, United Kingdom

Background: Diffuse B cell lymphoma, the most common type of Non-Hodgkin's lymphoma, typically presents as a clinically aggressive and heterogeneous group of disorders with a variable response rate to standardised rituximab; cyclophosphamide, doxorubicin, vincristine, prednisone(R-CHOP) chemotherapy. Recent BSH guidelines have addressed diagnostic work up and prognostic dependent management steps with emphasis on high risk and frail individuals. Patients with a poor performance ability are recommended for G-CSF prophylaxis in patients above the age of 65 years. Those with high numbers of comorbidities and impaired performance should also be considered for a steroid course prior to chemotherapy or modified treatment. The International Prognostic index (IPI) takes into account age at diagnosis, raised serum Lactate dehydrogenase, stage, bulky disease and performance status and gives an indication for low risk and high risk mortality.
Aims: To evaluate departmental adherence to national guidelines specifically focusing on the management of high risk and frail individuals. Also to study the trends between the prognostic scores and characteristics of patients who developed complications and mortality.
Methods: Data was collected from electronic records of 48 patients at Wigan Royal Infirmary. 32 Patients before Guidelines and 17 patients post guidelines.
Results: 93%(14 of 15) of WHO performance scores were not calculated post guidelines as compared to 66%(21 of 32) pre guidelines. 86% of patients above 65 years, did not have scores but incidentally had above stage three disease and more than two comorbidities, classing them frail. 33% of these did not receive GCSF or steroid prophylaxis. 29% of patients without a score died and 14% relapsed. 67% (10 of 15) of patients developed complications such as Neutropenic sepsis, oesophageal ulcers, recurrent infections, pulmonary embolisms and superior vena cava thromboses. No prognostic scores were calculated in this group hence the difficulty in understanding whether certain individuals would have benefited from appropriate prophylaxis. However 60% (6 of 10) of patients with complications had high co-morbidities numbers and were complicated by 3 deaths. There was a 19% mortality (6 of 32) pre guidelines of which 34% had an IPI score of Intermediate risk and 33% were under the age of 51. Mortality post guidelines were 46%(7 of 15) of which 57% (4) were under the age of 51years. Out of these young mortalities, one case was given steroid prophylaxis and 1 case had a low risk IPI.
Summary/Conclusion: This small capture of data may give an indication of how the current IPI score may not encompass all the key characteristics that predict high mortality. With surplus deaths in ages below 65; this may also indicate the need to expand the criteria for individuals who might benefit from prophylaxis treatment. Further study into characteristics of young mortality, associated family history, autoimmune disease, weight and occupational exposures can guide better management of potential high risk individuals. The numbers of non-adherence to the guidelines in this data set may also indicate the need to evaluate how long it takes for guidelines to be practiced and whether alternate means of education and delivery is needed apart from publishing.

PB1795

FOLLICULAR LYMPHOMA WITH C-MYC REARRANGEMENT PLACE OF THERAPY INTENSIFICATION

A. Misyurina[1,*], S. Kravchenko[1], A. Kovrigina[1], L. Plastinina[1], E. Nesterova[1], T. Obukhova[1], V. Misyurin[2], A. Misyurin[2], A. Magomedova[1], F. Babaeva[1], A. Vorobiev[1]

[1]National Research Center for Hematology, [2]N.N. Blokhin National Research Center for Oncology, Moscow, Russian Federation

Background: Presence of secondary *c-MYC* rearrangement (c-MYC-R) in patients with follicular lymphoma (FL) can predispose to a histologic transformation of FL and aggressive clinical course of the disease. That could be explained by the fact that finding of a secondary chromosomal break of *c-MYC* along with inactivation of tumour suppressor genes (*TP53, CDKN2A/B, B2M*) is one of predisposing factors to FL transformation Therapeutic approaches to treatment of FL with -*MYC*-R have not yet been clearly defined.
Aims: To describe clinical characteristics and treatment efficacy of FL patients presenting with *c-MYC*-R.
Methods: From 2015 to 2018 in National Scientific Center, were diagnosed 8 cases of FL with *c-MYC*-R (5 males and 3 females). Median age was 34,5 years (from 30 to 57). Median of follow-up was 8,8 months (from 5 to 25,6). Taking into account that in the majority of cases, except of *c-MYC* locus translocation, a tumour was represented by FL 3B, transformed FL or blastoid variant of FL, we had an intention to treat with R-(DA)-EPOCH, what was more intense than commonly used treatment approaches of FL. In case of incomplete antitumor response, autologous stem cell transplantation (auto-SCT) was planned.
Results: 7 out of 8 pts had a widespread tumour, ECOG≥2, 6-increased LDH activity, multiple extranodal involvements. In 6 cases tumour manifested with FL grade 3B; in 3 of them were revealed signs of large-cell transformation; in 2-with FL grade 3A with blastoid morphological features. In 4 out of 4 cases which had been stained with c-MYC, c-MYC expression was≥40%. 3 cases (FL grade 3B with foci of DLBCL) were BCL2-negative (<50%). Median of Ki-67 was 80% (40-85%). All 8 cases were positive for *c-MYC*-R. Pts, who manifested with FL grade 3A, had *c-MYC* and *BCL2* rearrangements (*c-MYC/BCL2*-R), with FL grade 3B-*c-MYC/BCL6*-R in 3 cases, in case of FL transformation into DLBCL were revealed *c-MYC/BCL2/BCL6-R*. This distribution highlights common pathogenesis between FL3B and DLBCL. G-banding was performed in 7 pts and revealed complex karyotype abnormalities. Five out of 8 of pts with FL underwent R-(DA)-EPOCH, 3-R-CHOP-21. In a group of 5 pts after R-DA-EPOCH, 2 pts had complete remission (CR) (one case of FL 3A with *c-MYC/BCL2*-R, another case of FL 3B with solely *c-MYC*-R), 3 pts needed second-line treatment (R-DHAP) due to progressive disease (PD) (2 cases of FL 3B with *c-MYC/BCL6-R*) or partial remission (PR) (1 case of FL 3A with *c-MYC/BCL2*-R). The last one achieved CR after 2 R-DHAP, later auto-SCT was performed. Another pt had stable disease (SD), auto-SCT was planned. Third one died due to progressive disease (PD). Three pts underwent R-CHOP: one case of FL 3B with *c-MYC/BCL6*-R had CR after 5 R-CHOP, but soon died due to bleeding of unknown source. Two another pts had PD after R-CHOP (one pt with triple-hit lymphoma died due to PD, another pt with FL 3B and solely *c-MYC*-R is alive with signs of disease). Thus, from 8 pts only 5 are alive, 2 of them with disease. Auto-SCT wasn't performed in spite of intention in two cases due to fast lymphoma progression.
Summary/Conclusion: FL with *c-MYC* rearrangement especially in combination with translocations involving *BCL2* and/or *BCL6* represents an aggressive tumour which requires more intensive approach than R-CHOP. Patients with FL who didn't achieve CR at the first line of treatment might have benefited from high dose therapy following auto-SCT. Otherwise, new treatment approaches are needed (CAR T-cells, clinical trials).

PB1796

A CNS INVOLVEMENT IN PATIENT WITH HAIRY CELL LEUKEMIA-PRIOR CNS INFECTION WITH SUBSEQUENT LEUKEMIA BREAKTHROUGH OR DISGUISED LEUKEMIA IN CNS FROM ONSET?

M. Smiljanic[1,*], M. Todorovic Balint[1,2], D. Antic[1,2], B. Mihaljevic[1,2]

[1]Clinic of Hematology Clinical Centre of Serbia, [2]Faculty of Medicine, Belgrade University, Belgrade, Serbia

Background: Hairy cell leukemia (HCL) is a rare chronic lymphoproliferative disease, comprising 2% of all adult leukemia cases. With current treatment, including purine nucleoside analogs, the prognosis of HCL is favorable, with some reports of 12-y overall survival rate of 87%. Usually HCL presents with cytopenias, enlarged spleen, massive lymphadenopathy and secondary infections, as tumor cells predominantly affects bone marrow and spleen, but rarely it can be presented with atypical involvement of bone, liver, skin, neurologic, or vascular tissue. CNS involvement, reported in only few cases, is extremely rare, most neurological signs and symptoms are usually related with infections.
Aims: To present diagnostics, clinical course and treatment outcome of our patient diagnosed with variant HCL (vHCL) and very rare leukemia CNS involvement.
Methods: Case report of a rare vHCL with CNS involvement.
Results: Our female patient, aged 68, was initially admitted as a high suspicion for subacute meningoencephalitis, in the Clinic for Infectious Disease, Clinical Centre of Serbia. She presented with persistent high fever and neurological/ neurological related symptoms (generalized convulsions, aphasia, confusion, nausea and vomiting) of which some (confusion, nausea) appeared 3 months earlier. Magnetic resonance (MR) of the brain was highly suspicious for bilateral frontal lobes empyema. Serological and cerebrospinal fluid (CFS) analyses for WNV, Wright, HSV1 and 2, Toxoplasma Gondii, Rubeolla, CMV and B. Burdgoferii, as well as for TBC and Cryptococcus were all negative. Lumbal puncture test for malignant cells was negative, but revealed a large number of small and active lymphocytes. Blood count showed bicytopenia (hemoglobin 9.7g/dl, WBC $1.7x10^9$/l). Laboratory analyses showed high C-reactive protein and ESR. Radiography findings (ultrasound and CT) revealed no enlarged spleen or lymph nodes. However, CSF Flow cytometric immunophenotyping (FCI) analysis revealed signifi-

cant (56%) presence of B-Non Hodgkin Lymphoma (B-NHL) cell population, $CD19^{+high}CD20^{+medium}CD103^{+low}CD45^{+high}/SSC^{low}$, confirming malignant CNS involvement. Patient was initially treated with antiepileptics, broad spectrum antibiotics, antituberculosis and antifungal therapy. After subsequent admission in our Clinic, hematological diagnostics was performed. Peripheral blood smear was indicative for vHCL, showing atypical TRAP+. FCI analyses of the peripheral blood lymphocytes and of bone marrow revealed presence of atypical monoclonal mature B cells in peripheral blood (170cells/µl, 10% of WBC) and in bone marrow respectively (24% of nuclei cells), implying presence of B-NHL, CD5-, CD10-, CD103+ in leukemic phase. CLL score was 3. Aspiration biopsy, as well as bone marrow biopsy, showed significant (up to 90%) presence of small cell lymphoid infiltrates. Following these findings and regarding absence of lymphoid tissue tumor burden, lack of enlarged spleen, and aggressive clinical presentation, we diagnosed our patient with vHCL and extremly rare leukemia involvement of CNS. Patient was treated accordingly with Cladribine, one cycle, plus intrathecal terapy with Metotrexate. Post treatment analyses showed good partial responce with complete regresssion of neurological signs and symptoms and normal posttherapeutical brain MR finding.
Summary/Conclusion: We presented a case of an extremely rare leukemia involvement of CNS with vHCL cells. Leukemia cells were found in CSF and final regression of neurological signs and symptoms was registered after Cladribine treatment.

PB1797

MODIFIED R-IDARAM TREATMENT IN CENTRAL NERVOUS SYSTEM LYMPHOMAS: A SINGLE CENTRE EXPERIENCE

S. Maral[1,*], M. Albayrak[1], C. Pala[1], H.B. Afacan Ozturk[1], A. Yıldız[1], O. Sahin[1], H. Okutan[2]

[1]Hematology, Dıskapı Research and Training Hospital, [2]Hematology, Losante Hospital, Ankara, Turkey

Background: Central nervous system (CNS) lymphomas are aggressive entities which have a poor prognosis. Treatment has improved significantly after the high-dose methotrexate(HD-MTX)-based regimen used in recent years. The optimal treatment approach for patients with CNSL is still unclear, and there is no standard therapeutic approach for these patients.
Aims: The aim of this paper was to present the cases of 9 CNS lymphoma patients treated with the modified R-IDARAM protocol to shed some light on the effectiveness, tolerability and toxicity of this protocol.
Methods: A total of 9 patients, 7 with PCNL and 2 with SCNL, were treated with the modified R-IDARAM regimen,comprising rituximab 375 mg/m^2 (day 1), idarubicin 10 mg/m^2 (days 2 and 3), dexamethasone 100 mg/m^2 (12-hr infusion on days 2, 3 and 4), cytosine arabinoside (ARA-C) 1 g/m^2 (1-hr infusion on days 2 and 3), methotrexate (MTX) (3 g/m^2, 6-hr infusion on day 4) with folinic acid rescue, ARA-C 40 mg plus 15 mg MTX and dexamethasone 8 mg (via intrathecal route on days 1 and 8)The PCNSL patients were diagnosed from the examination of mass biopsy materials or surgically resected specimens. The Karnofsky Performance Status (KPS) scale was used to evaluate the performance status of patients. The risk profile and prognosis of patients were determined according to Memorial Sloan-Kettering Cancer Center (MSKCC) Prognostic Scoring system.Two additional courses of R-IDARAM (total four courses) were applied and all courses were given every 28 days.Complete remission (CR) referred to resolution of all apparent tumors. Partial Resolution (PR) of >50% of assessable disease, determined as the product of two diameters of measurable lesions, minor response/no change (MR/NC) was defined as a reduction of<50% of measurable disease but with no disease progression, and progressive disease (PD). The response was evaluated with cranial magnetic resonance imaging (MRI) for the PCNSL patients and additional thoraco-abdominal CT was performed for SCNSL.In patients where CR was achieved, follow-up was made every 3 months for 2 years and then every 6 months. The toxicity of the regimen was evaluated after all courses and graded according to the National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE v4.0).
Results: CR was achieved in 4/7 PNCLS and 1 / 2 SCNCL patients after 2 courses. These PNCLS patients and 1 SCNCL patient are still being followed up without disease progression to date (66, 75 and 4 months, respectively).During the first course, 2 PCSNL patients died because of severe infection and 1 SCNSL patient died because of progressive CNS lymphoma with 1-month survival.All patients had grade 3-4 hematological side-effects including thrombocytopenia and neutropenia, and intravenous antibiotherapy was required during febrile episodes. Severe mucosal problems were experienced in 2 patients and grade 3 peripheral neuropathy in 1 patient. No cranial or neurological complications attributed to radiotherapy were detected.No cardiac or renal side-effects were seen in any patient.
Summary/Conclusion: The data of a small number of patients are presented here. Most patients achieved CR after induction therapy but this was not maintained for a long time. Few patients were able to complete the therapy completely due to poor performance status and social problems. Therefore, the long-term results are not satisfactory. More clinical trials are still needed to develop new therapeutic methods for CNSL. Nevertheless, it seems to be a good option with response rates, manageable toxicity and a well-tolerated regimen.

PB1798

MEDIASTINAL GREY ZONE LYMPHOMA

Y. Mangasarova*, A. Magomedova, A. Misyurina, E. Nesterova, S. Kravchenko

National Research Center for Hematology, Moscow, Russian Federation

Background: Mediastinal B-cell lymphomas present in the mediastinum and are most frequent in young patients. Nodular sclerosis Hodgkin lymphoma (NS HL) and primary mediastinal B-cell lymphoma (PMBL) are common types, whereas mediastinal grey-zone lymphoma (MGZL) is extremely rare and has pathological features intermediate between NS HL and PMBL. The indeterminate pathobiology of MGZL led to uncertainty regarding therapeutic strategy. Clinical characteristics of MGZL and treatment strategy have not been characterized.
Aims: To describe clinical features of patients with MGZL.
Methods: From 2007 to 2018 years, 20 patients were diagnosed with MGZL (according to WHO criteria) in National Research Center for Hematology scow Russian Federation. The median age of patients was 32 years (from 19 to 54). There were 7 males, 13 females. Increased LDH activity was revealed in 69% of pts. Bulky mediastinal disease manifested in 45% of pts. A metachronous development of NS HL and PMBCL was observed in 2 out of 20 pts. Synchronous onset of classical HL and PMBL occurred in 18 out of 20 pts. reatment was completed in 16 out of 20 pts. Therapeutically, the Hodgkin-like pathological features of MGZL was treated like HL. Cases with strong expression of the CD20 were treated with rituximab. Cases with features of PMBL, with rituximab-based regimens as with PMBL. R-DA-EPOCH/m-NHL-BFM-90 were used in 12 out of 16 pts, R-BEACOPP-14 in 4 out of 16 patients. Autologous peripheral blood stem cell transplantation (auto-SCT) with BEAM conditioning regimen after first-line treatment was performed in 6 out of 16 pts. Therapeutically, the Hodgkin-like pathological features of MGZL was treated like HL. Cases with strong expression of the CD20 were treated with rituximab. Cases with features of PMBL, with rituximab-based regimens as with PMBL. R-DA-EPOCH/m-NHL-BFM-90 were used in 12 out of 16 pts, R-BEACOPP-14 in 4 out of 16 patients. Autologous peripheral blood stem cell transplantation (auto-SCT) with BEAM conditioning regimen after first-line treatment was performed in 6 out of 16 pts.
Results: After R-DA-EPOCH/m-NHL-BFM-90 therapy CR was achieved in 6 out of 16 pts. Four out of 16 pts had PR and underwent 2 R-DHAP courses followed by auto-SCT. Early relapse occurred in 1 out of 16 patient. Two out of 16 were primary resistant and underwent the PD-1 blockade.
After R-BEACOPP-14 therapy CR was achieved in 3 out of 16 pts, 1 out of 16 pts had PR and underwent 2 R-DHAP courses followed by auto-SCT, but early disease progression led to lethal outcome. Median follow up was 32 months.
Summary/Conclusion: Our data suggest that intensive treatment could improve outcome of this rare and aggressive disease.

PB1799

CLINICAL AND HEMATOLOGICAL MARKERS OF THE RESPONSE FORECAST TO FIRST-LINE THERAPY IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA

S. Samarina[1,*], E. Nazarova[1], N. Minaeva[1], E. Osipova[1], S. Gricaev[2]

[1]Federal State Institute of Science "Kirov Research Institute of Hematology and Blood Transfusion of the Federal Medical and Biological Agency of Russia", Kirov, [2]Federal State Institute "Russian Research Institute of Hematology and Transfusion of the Federal Medical and Biological Agency of Russia", St. Petersburg, Russian Federation

Background: Diffuse large B-cell lymphoma (DLBCL) is the most common aggressive type of non-Hodgkin's lymphoma, which is characterized by pronounced biological heterogeneity and manifested by various response to induction therapy and the timing of the relapse onset. The risk factors used in clinical practice is not sufficient for correct stratification of patients. This

makes it difficult to plan the duration and intensity of therapy. Thus, the current direction is the allocation of new highly informative markers, which help to individualize the choice of the treatment method of DLBCL.
Aims: To evaluate the prognostic potential of individual clinical and hematological indicators as predictors of the first-line of therapy effectiveness in DLBCL patients.
Methods: A retrospective analysis of the 99 patient's cases was conducted, the age median was 57 (37-80) years. The criteria for study inclusion were: patient's age, DLBCL type, DLBCL morphological subtype, IPI index, disease stage, B-symptoms, LDH level, the method and effectiveness of induction therapy, the status of the patient and the disease in post-induction monitoring. All patients receiving R-CHOP treatment were divided into 4 groups: 54 patients with complete response (CR), 14 with partial response (PR), 16 with resistance to first-line therapy and 9 with early relapse (ER). The median of follow-up duration was 51 (1-60) months.
Results: Among the examined, patients younger than 60 years with a low IPI index were significantly more likely observed (37.7 *vs* 13.3%, $p<0.0076$). Low IPI was reported more often in patients with CR than in resistant form (37 *vs* 0%, $p<0.001$). The frequency of high IPI in groups with CR, PR and resistance to therapy was also significant differed: 7.4, 50 and 68.8%, respectively ($p=0.002$). B-symptoms in the beginning of the disease in 1, 2 and 4 groups were observed in 42.6, 71.4 and 88.9% of patients, respectively. At the same time, in the group with PR, the frequency of B-symptoms was significantly higher than in patients with CR and ER ($p=0.05$ *vs* $p=0.013$, respectively). At the first stage of the disease, the CR frequency was significantly higher than the PR (25 *vs* 0%, respectively, $p=0.016$). It was found that the depth of response correlated with the serum LDH level. LDH value within the references were more often observed in patients with CR than with PR (44.4 *vs* 14.3%, $p=0.039$) or resistant variant (44.4 *vs* 6.3%, $p=0.005$). There was a tendency to decrease the effectiveness of R-CHOP in patients with non-GCB subtype of DLBCL in comparison with GCB type: 26.9 *vs* 73.1% in group 1 ($p=0.174$). Four-year disease-free survival (DFS) in patients with CR was not achieved and was 6 months in the group with PR ($p=0.001$). Four-year overall survival (OS) in the patients with CR, PR and ER was not achieved, and in patients with resistant variant it was 12 months ($p<0.001$).
Summary/Conclusion: A correlation was found between the IPI index, the presence of B-symptoms and the LDH level with the depth of response to induction therapy R-CHOP in DLBCL patients, which indicates a correlation of tumor burden with the effectiveness of treatment. The variability of individual indicators does not allow to correctly predict the probability of reaching a response to treatment. It was found that CR is associated with an increase of the DFS and OS duration. It seems reasonable to search for new risk markers for the early initiation of aggressive treatment in the case of the predicted low efficacy of the standard R-CHOP induction regimen.

PB1800

ACQUIRED HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS AMONG HEMATOLOGIC PATIENTS: A SINGLE CENTRE EXPERIENCE

N.S. Fracchiolla*, L. Pettine, V. Mattiello, A. Freyrie, M.C. Goldaniga, M. Sciumè, A. Cortelezzi

Oncohematology Division, IRCCS Ca' Granda-Maggiore Policlinico Hospital Foundation and University of Milan, Milan, Italy

Background: Hemophagocytic Lymphohistiocytosis (HLH) is characterized by activation of cytotoxic T-cells and overwhelming cytokine production and release, resulting in an extreme inflammatory response. Primary HLH is most common in children and is genetically driven. Secondary HLH recognises multiple causes, as drugs, autoimmune disease, infection or cancer. Secondary HLH may occur during hematologic neoplasia, as first manifestation of them, before or during the treatment of a recognized malignancy, or associated with relapsing/progressive disease. Hematological malignancy-associated HLH may present an even more severe outcome than primary HLH. Despite the availability of diagnostic criteria, the diagnosis of HLH remains challenging, due to the multiple variables involved and its potential rapidly catastrophic presentation.
Aims: To describe the treatment and outcome of a monocentric, real-life, small cohort of secondary HLH.
Methods: We describe the diagnosis, clinical features, treatment and outcome of five consecutive patients (pts) with secondary HLH presenting at our Centre between March 2016 and December 2017.
Results: All pts received a diagnosis of HLH based on the HLH-2004 criteria (Table 1). Median age was 54 years (range 23-70), and 3 were male. Associated conditions included hematologic malignancies (80%) and infections (40%). Four pts had hematologic malignancy in relapse (80%): 3 non-Hodgkin lymphoma (B-cell, n=1; T-cell, n=2), 1 CLL. Two pts had also an underlying CMV and EBV viral infection. One patient developed HLH in the setting of Kaposi's sarcoma. All cases presented with fever, elevated ferritin (≥500 µg/l) (median 34.126 µg/l, range 9.130-100.000 µg/l) and high triglycerides (≥265mg/dL)(median 371 mg/dl, range 331-428 mg/dl). Other features at HLH diagnosis were: 4 pts (80%) had splenomegaly, 4 pts (80%) had new onset of ≥2 cytopenias, and 1 pt (20%) had low fibrinogen (≤150 mg/dl). Bone marrow examination was performed in 3 pts, 2 had morphological evidence of hemophagocytosis (40%). NK-cell activity and sIL2R testing were not performed. The median lactate dehydrogenase (LDH) was 1.784 U/L (range, 458-4.060 U/L). Increase in bilirubin and transaminases or creatinine were seen in 3 and 2 patients, respectively. All patients received etoposide and dexamethasone treatment, one patient started CHOEP, and one started ibrutinib to control underlying malignancy. One pt received rituximab for EBV infection and one patient received valganciclovir for CMV infection. Two pts died within 30 days from diagnosis, while 3 pts are in HLH CR.

Table 1.

Patients characteristics	
Number	5
Median age, years (range)	54 (23-70)
Male gender, number (%)	3 (60)
Underlying disease, number (%):	
B-cell lymphoma	1 (20)
T-cell lymphoma	2 (40)
CLL	1 (20)
Kaposi sarcoma	1 (20)
HLH-2014 diagnostic criteria, number (%):	
Fever	5 (100)
Splenomegaly	4 (80)
Cytopenias affecting ≥2 lineages	4 (80)
Hypertriglyceridemia (≥ 265 mg/dL)	5 (100)
Hypofibrinogenemia (≤ 150 mg/dl)	1 (20)
Hemophagocytosis in tissue	2 (40)
Ferritin > 500 mg/L	5 (100)
Outcome, number (%):	
< 30 day mortality	2 (40)

Summary/Conclusion: Diagnosis of malignancy-associated HLH in adults is particularly challenging due to the multiplicity of confounding variables and evolution rapidity, possibly leading to a delayed recognition. HLH should be suspected in patients with hematologic malignancies, in particular in T-cell lymphomas, or in the presence of EBV and CMV infections, presenting fever, cytopenias, splenomegaly and ferritin elevated to more than 500 mg/L, that indicate an underlying uncontrolled inflammatory state. A high degree of clinical suspicion allows a prompt diagnosis and treatment, that remain the key factors in the prevention of a HLH catastrophic clinical course.

PB1801

IBRUTINIB AS SALVAGE TREATMENT IN TWO MANTLE CELL LYMPHOMA (MCL) PATIENTS WITH CENTRAL NERVOUS SYSTEM INVOLVEMENT (CNSI)

N. Giannakoulas*, F. Panitsas, M. Palassopoulou, G. Stefani, A. Markou, L. Mavroeidis, T. Testa, E. Bouronikou, G. Vassilopoulos

Hematology Department, School of Health Sciences University of Thessalia, Larissa, Greece

Background: CNSi is extremely rare at MCL diagnosis but more frequent at relapse (4-8%) with poor prognosis (median survival<6 months). Leptomeningeal infiltration is more frequent than parenchymal disease. Treatment includes CNS directed chemotherapy crossing the blood-brain barrier (BBB). Consolidation with HDT/ASCT can be considered for fit patients. Irradiation and palliative care are also options in relapsed/refractory (R/R) or unfit cases. Ibrutinib has shown significant single agent activity in R/R MCL.
Aims: We present two cases of MCL patients with secondary CNSi, successfully treated with Ibrutinib.
Methods: Case 1: A 58-year-old male was diagnosed with MCL stage IV, MIPI score high and ki-67 high (40%) in November 2011. He achieved CR with first line treatment (R-CHOP, 8 cycles followed by R maintenance). Three years after initial diagnosis (November 2014) he developed eye proptosis with pain and periorbital oedema. MRI scan showed intraorbital mass infiltrating the rectus muscles and extending into the maxillary sinuses. Further imaging only showed cervical lymphadenopathy. CSF examination was

negative. He was treated with high dose Methotrexate and Cytarabine and achieved partial response. Additional treatment with Bendamustine-Rituximab (6 cycles, April 2015-September 2015) led to further radiological improvement.He suffered second disease recurrence in the same area 12 months later (September 2016). Whole body imaging with PET/CT scan revealed hypermetabolic foci inside the right frontal lobe with high uptake compared to brain parenchyma (SUV 16.7). CSF examination was negative. MRI confirmed the presence of intraparenchymal solid lesion. He was commenced on Ibrutinib 540 mg/d in November 2016. Follow-up imaging in March 2017 showed significant shrinkage of the intracranial tumor and complete response was seen in July 2017. Latest MRI imaging in January 2018 showed that he remains in continuous CR on ibrutinib treatment.
Results: Case 2: A 58 year-old male was diagnosed with stage IV, MIPI high MCL in November 2013. He achieved good PR after 6 cycles of R-CHOP. He was not considered eligible for HDT/autologous transplant consolidation. Six months later (October 2014) disease relapsed with Waldeyer ring involvement (confirmed by biopsy, Ki-67 75%) and CNSi (leptomeningeal disease only). He was treated with three cycles of HyperCVAD/MA and IT chemo to CR. In June 2015, there was systemic relapse with CNSi (leptomeningeal and parenchymal disease). He received salvage R-DHAP with responding systemic disease but only partial CNS response. There was CNS progression in October 2015, refractory to high dose Methotrexate. He was started on Ibrutininb 560 mg/day in November 2015. There was immediate response of CNS disease with CR on imaging 10 months later. Systemic disease remained in remission throughout, however he developed isolated CNS relapse in March 2017 (leptomeningeal and parenchymal). Disease was refractory to high dose Methotrexate but responded (PR) to Bendamustine, Cytarabine, Dexamethasone and Rituximab plus IT chemo (4 cycles). There was progression of CNS disease (parenchymal only) again in February 2018. He was started on Rituximab- Ifosfamide-Etoposide. Formal response assessment is pending.
Summary/Conclusion: Ibrutinib has been shown to rapidly cross the BBB and has been reported to have impressive clinical results in cases with CNS MCL relapse. Our experience described herein has also been positive. Salvage of MCL patients progressing on Ibrutinib treatment is difficult and outcomes are generally poor.

PB1802

PRIMARY TONSIL DIFFUSE LARGE B CELL LYMPHOMA IS CLINICOPATHOLOGICALLY DIFFERENT FROM NODAL DIFFUSE LARGE B CELL LYMPHOMA IN TAIWAN

C.-F. Yang*

Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei, Taiwan, Republic of China

Background: Diffuse large B cell lymphoma (DLBCL) is the most common lymphoma. It is a highly heterogeneous group of neoplasms and patients have a variable clinical course and prognosis.
Aims: In this work, we try to study the difference of primary tonsil DLBCLs and nodal DLBCLs.
Methods: We analyzed a cohort of 103 primary tonsil diffuse large B cell lymphomas (DLBCLs) retrieved from our pathological file from 1998 to 2015, and compared 74 nodal DLBCLs from 2012 to 2013.
Results: In those cases with available data, the primary tonsil DLBCLs were more common confined to stage I–II disease (71%, 65/92 *vs* 33%, 24/73, P<0.001), and more often revealed a germinal center B-cell-like (GCB) immunophenotype (56%, 15/27 *vs* 29%, 17/59, P=0.029). The 5-year overall survival (OS) of primary tonsil and nodal DLBCL patients were 72% *vs* 58.9%(P=0.008).
Summary/Conclusion: Primary tonsil DLBCLs display distinct clinicopathologic features compared with nodal DLBCLs in Taiwan, with usual localized-stage disease, common GCB immunophenotype, and a better outcome.

PB1803

CLADRIBINE IN TYPE II REFRACTORY CELIAC DISEASE (RCD): A SINGLE INSTITUTION EXPERIENCE

A.I. Gregorini[1,*], V. Ferla[1], F.G. Rossi[1], A. Pompa[1], F. Guidotti[2], M.C. Goldaniga[1], V.B. Valli[2], A. Cortelezzi[1,2], L. Baldini[1,2]

[1]Hematology Unit, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, [2]Oncology and Hemato-oncology, University of Milan, Milan, Italy

Background: RCD is defined by no response to a year of gluten free diet (GFD) with persistence of malabsorption and intestinal villous atrophy. A biopsy of upper gastrointestinal tract is necessary for diagnosis of the two RCD subtypes: type I characterized by a normal phenotype of intraepithelial lymphocytes (IEL) with surface CD3 and CD8 expression; type II characterized by clonal expansion of abnormal IEL lacking surface markers CD3, CD8 and T-cell receptor and preserved intracellular CD3 expression. RCD II has a severe clinical presentation due to ulcerative jejunitis responsible for severe protein loss enteropathy and malnutrition. The risk of transformation in enteropathy associated T cell lymphoma (EATL) is about 33-52% within 5 years after diagnosis. Only 30-40% of patients (pts) achieve histological response and in most cases the clinical improvement is transient with steroids. Immunosuppressive therapy has failed to show a histological response, even increasing the risk of evolution in EATL. Cladribine, a purine analogue, at the dosage of 0.14mg/kg per day for 5 days has induced clinical and histological response.
Aims: To achieve an early and accurate diagnosis of RCD type II pts and to evaluate clinical and histological response to purine analogues treatment.
Methods: We retrospectively collected clinical, laboratory, endoscopic end histological data of two RCD type II pts treated with subcutaneous (SC) cladribine from 2015 in our haematology unit.
Results: The first pt was a 63 years old man diagnosed with CD since 2007. In 2012 he underwent esophagogastroduodenoscopy (EGD) for diarrhea and weight loss with diagnosis of RCD I. A steroid therapy was started with transient clinical benefit. In July 2015, a new EGD was performed for recurrence of symptoms and showed a 60% T-IEL infiltrate with aberrant phenotype and a monoclonal TCR on a polyclonal basis. Video capsule endoscopy (VCE) demonstrated widespread atrophy in more than half of the small intestine, while CT scan and PET resulted negative. Because of steroid refractoriness, a treatment with SC cladribine was started. He underwent three cycles every six months, with a 30% dose reduction for the first two cycles. Treatment was well tolerated, without hematological toxicity. After III cycles he had weight gain and resolution of diarrhea and a macroscopic improvement of ileal athrophy and ulcers, without significant reduction of T cell infiltration. The second pt was a 62 years old woman diagnosed with CD in January 2016. A EGD revealed a 60% T-IEL infiltrate with aberrant phenotype and monoclonal TCR on a polyclonal basis. VCE demonstrated widespread signs of jejunal atrophy and erosions, while CT scan and PET were negative. Since steroids were ineffective, she underwent two cycles of SC cladribine. Treatment was well tolerated. There was an improvement of clinical symptoms (weight gain and resolution of diarrhea) and of ileal atrophy and ulcers, with a 50% reduction T IEL infiltrate.
Summary/Conclusion: In conclusion both pts showed a clinical and histological response to SC cladribine without hematologic toxicity or infectious complications: this indicate that this treatment could be a safe and effective option in elderly pts affected by type II RCD. Furthermore the outpatient administration of the treatment also lead to a reduction of pt discomfort and costs related to hospitalization.

PB1804

PLASMABLASTIC LYMPHOMA IN HIV-NEGATIVE PATIENTS: EXPERIENCE OF SINGLE CENTER IN SPAIN

G. Pinto*, M. Calbacho, J. López

Hematology, Hospital Ramon Y Cajal, Madrid, Spain

Background: Plasmablastic lymphoma (PB) is a low incidence subtype of lymphoma with special clinical features, which is mainly seen in patients with HIV, but not exclusively. Currently, there is no standard of care and prognosis remains poor. Besides, little is known about its clinical behavior in HIV-negative patients.
Aims: Describe the cases of PB in a single center in order to find diferences between HIV-negative and HIV-positive patients.
Methods: 9 patients were diagnosed between 2011-2016. Clinical features, treatment and overall survival (OS) were analized both in HIV-positive and HIV-negative patients.
Results: The main clinical features in the group HIV-positive *vs* HIV-negative are described in table 1. Median follow-up was 7.23 months. In the HIV-negative group, 3 patients (50%) had a post-transplantation PB (2 patients after bone marrow transplant, and 1 after liver transplant). Most of patients received treatments based on bortezomib added to standard doses of chemotherapy (VR-CAP scheme) or an intensified protocol (DA-EPOCH scheme). Other protocol (Rituximab monotherapy) was used in only one HIV-negative patient with stage II PB. The median OS in HIV-positive and HIV-negative patients was 3.5 and 25.3 months respectively. All HIV-positive patients died during the first year, whilst HIV-negative patients had a survival rate of 66% at 1 year and 50% at 2 years.
Summary/Conclusion: Among the patients with PB, HIV-negative group tends to share the same clinical features than HIV-positive group, but has a

better prognosis in terms of OS even in the post-transplant setting. Both treatments (standard *vs* intensified) show to be effective, but it is necessary further studies to determine an optimal treatment protocol. On the other hand, outcome in HIV patients with PB is dismal despite bortezomib based or intensified protocols.

Table 1.

CLINICAL FEATURES	HIV-positive (N=3)	HIV-negative (N=6)
Mean age	48.6	56.8
Male sex	66%	85%
Extranodal disease	66%	85%
Stage III/IV	100%	71%
MYC mutation	33%	42%
Histological detection of EBV	66%	42%
Human herpes virus-8	33%	0%
CNS involvement	0%	0%
VR-CAP scheme	66%	50%
DA-EPOCH scheme	33%	33%

Bleeding disorders (congenital and acquired)

PB1805

INCORPORATION OF EVIDENCE BASED GUIDELINES ON BLEEDING RISK ASSESSMENT PRIOR TO ENT SURGERY INTO PRACTICE: REAL TIME EXPERIENCE

N. Al-Marhoobi[1], M. Maktoom[2,*], M. Elshinawy[3,4], H. Nazir[4], K. Al hashmi[5], R. Al-abri[6], K. Macki[7], A. Al-Rawas[4], Y. Wali[4]

[1]ENT surgery, [2]Pediatrics, Oman Medical Specialty Board, Muscat, Oman, [3]Pediatrics, Faculty of Medicine, Alexandria University, Alexandria, Egypt, [4]Pediatrics, Sultan Qaboos University Hospital, [5]Hematology, Armed Forces Hospital, [6]ENT surgery, Sultan Qaboos University Hospital, [7]ENT surgery, Armed Forces Hospital, Muscat, Oman

Background: In spite of guidelines recommending the no need for coagulation profile prior to ENT surgeries when challenging history of bleeding is negative, yet surgeons still practice it. Cost and delaying surgeries are major issues faced when insignificant abnormalities are found in the coagulation profile results. In 2008, British Committee for Standards of Hematology has published guidelines (1) on assessing the bleeding risk prior to surgeries or invasive procedures, which stated that the indication for sending a coagulation profile is based on the bleeding history of the patient.
Aims: This study aims to identify the reasons of ENT surgeons for requesting pre-operative coagulation screening; prothrombin time (PT) and activated partial thromboplastin time (APTT) in spite of the available evidence and guidelines of their poor correlation with bleeding risk.
Methods: The current work was based on a survey conducted at 3 tertiary care facilities in the Sultanate of Oman for surgeons who performed adenoidectomy/adeno-tonsillectomy and other ENT surgical procedures during the period from 1st Jan 2017 to 1st September 2017. The Survey was conducted for identifying the practice of the ENT surgeons prior to surgeries, either getting a challenging bleeding history from the patients/guardians or requesting a coagulation profile (PT, APTT) as well. Surgeons who decide to do coagulation profile were requested to identify their reason. Patients with proven or suspected bleeding disorder (based on the past and family history) were excluded.
Results: The study included data from 730 patients who underwent ENT surgical procedures. They were 432 males and 298 females. Their mean age was 19.6 ± 16.92 year. Out the 730 patients, 372 patients were interviewed for a challenging bleeding history alone (group 1) and 358 were interviewed plus a pre-operative coagulation profile check (Group 2). Two patients had an intraoperative minor bleed that requires stitching (one in each group). Three patients in group 2 had post-operative secondary bleeding after 1 week that responded to local hemostatic measures. Twenty eight surgeons who preferred to do the coagulation profile for their patients answered the survey. Twenty two (78.5%) gave the reason of habitual practice and overprotection, 4 were not confident with the current evidence and 2 had previous bleeding experience with their patients.
Summary/Conclusion: Despite the current evidence of meta-analysis and the hospital guidelines, still many surgeons prefer to do coagulation check before ENT surgeries for different reasons. Surgeons need to be educated more on the current evidence of the superiority of the challenging bleeding history over the routine PT and APTT tests. This might reduce the waiting time for performing these procedures.

PB1806

GENETIC FACTORS POSSIBLY CONTRIBUTING TO COMPLICATIONS AFTER ORTHOPEDIC OPERATIONS IN HEMOPHILIA PATIENTS

T. Polianskaia*, I. Fevraleva, E. Karpov, N. Sadykova, M. Sampiev, G. Mishin, A. Golobokov, D. Petrovskiy, A. Koroleva, T. Tupoleva, A. Kovrigina, A. Sudarikov, V. Zorenko

National Research Center for Hematology, Moscow, Russian Federation

Background: The intensity and frequency of hemorrhagic manifestations in patients with certain form of hemophilia may vary. There are still no convincing data explaining the different clinical course of hemophilia. Despite comprehensive substitutive hemostatic therapy, some patients devel-

op severe arthropathy requiring surgical support. Frequency of purulent complications after arthroplasty in patients with hemophilia is higher than in the general population.
Aims: To study possible genetic factors that aggravate the course of hemophilia and increase the risk of complications after orthopedic operations.
Methods: 96 patients with severe hemophilia and arthropathy who underwent endoprosthesis replacement of the affected joint were included in the study. The mean age was 39.6 years (min 23, max 68): 75 (78.1%) with hemophilia A, 16 (16.7%) with hemophilia B and 5 (5.2%) with an inhibitory form of hemophilia. Histological studies of bone tissue in the area of the affected joint, taken during arthroplasty of the joint, were performed. Patients were examined for antibodies to hepatitis C and hepatitis C RNA. DNA samples were examined for genetic markers of hereditary hemochromatosis (mutations H63D and C282Y of HFE gene), thrombophilia (F5, MT677, MT1298, F2), polymorphisms of the vitamin D receptor gene (Taq1, Apa1 and Fok1) by means of real-time allele-specific polymerase chain reaction.
Results: Homozygous Taql and Apal polymorphisms of the vitamin D receptor gene in hemophilia patients was found in 7.3% and 18.8%, respectively, which corresponds to the literature data for the Russian population. Homozygous Fokl marker was detected in 27 patients (28%), which is 2.8 times more frequent than in general population (10%). Nine heterozygous cases (9.4%) of C282Y HFE gene mutations (none homozygous) and 38 heterozygous (39.5%) cases of H63D mutation (4 homozygous-4.2%) were found in hemophilia patients which is 1.5-2 times higher than the average incidence of these alleles in the Russian population. For thrombophilia markers frequencies were: F5-7 heterozygotes and no homozygotes; MT677-36 for the heterozygotes and 9 homozygotes; MT1298-35 heterozygotes and 8 homozygotes, and. Twelve patients had heterozygous mutations at the same time for MT677 and MT1298. In patients with hemophilia B, the frequency of homozygous thrombophilia mutations was higher (31.25%) than in hemophilia A (13.3%).
Summary/Conclusion: HFE gene mutations may possibly increase the deposition of hemosiderin in the joint tissues subsequently accelerating arthropathy progression. Since 91.4% patients in our sample are infected with viral hepatitis C, hemochromatosis markers may also complicate the course of hepatitis and increase the risk of complications. Homozygous Fokl marker of the vitamin D receptor gene is linked to increased risk of developing infectious complications, therefore in our cohort may increase the risk of purulent postoperative complications. Several alleles of the vitamin D receptor gene are correlated with increased rate of bone resorption and may also increase the risk of aseptic instability in the components of endoprostheses. The presence of thrombophilia markers in patients with hemophilia also may change the course of hemophilia in patients with the same initial level of the deficient factor requiring more individualized approach for hemostatic replacement therapy.

PB1807

UNDERLYING DISEASE OF THE ACQUIRED HAEMOPHILIA AFFECTS THE TREATMENT OUTCOME AND PROGNOSIS-CROATIAN EXPERIENCE

M. Vodanović[1,*], D. Pulanić[1,2], A. Boban[1,2], S. Zupančić Šalek[1,2,3]

[1]Dpt of internal Medicine, Division of Haematology, University Hospital Centre Zagreb, [2]School of Medicine, University of Zagreb, Zagreb, [3]School of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia

Background: Acquired haemophilia A (AHA) is a rare autoimmune disease, caused by antibodies (inhibitors) against coagulation FVIII and characterized by spontaneous hemorrhage in patients with no previous history of bleeding. Risk factors for the occurrence of AHA include advanced age and underlying diseases (malignancy, autoimmune disorders, pregnancy, and the postpartum period).
Aims: In this work we showed how the underlying diseases of acquired haemophilia A affect the treatment outcome and prognosis (deaths in patients).
Methods: We analyzed the results of fifteen patients (10 (66,7%) male,5 (33,3%) female), median age 71 (51-81) with AHA from July 2010 until December 2017, treated at the UHC Zagreb. Severe bleeding had 66,7% patients. Almost half of patients (46,7%) had FVIII activity<5 U/ dL. The median inhibitor titre at diagnosis was 5,8 (2,3–2000) BU/mL. In 7 patients (46,7%) were not identified underlying diseases associated with AHA. In 8 patients (53,7%) were identified underlying diseases; malignancies 3 (oligodendroglioma, B-CLL, IgM monoclonal gamapathy), autoimmune diseases 4 (autoimmune haemolytic anaemia in 2 patients, rheumatoid arthritis, polymyalgia rheumatica), 1 postinfective.
Results: Haemostatic therapy was initiated in 86,7% of patients (100% with severe bleeding) with AHA. First-line therapy consisted of bypassing agents (recombinant FVIIa in 13,3%, activated prothrombin complex concentrates in 73,3%), and all patients were treated with immunosupressive treatment (combination of steroids and cyclophosphamide in 13 patients, steroids alone in 2 patients). Rituximab alone was used in one patient as the second line treatment. Both group with underlying and without underlying disease were similar according to the median age 71, FVIII activity 5 *vs* 6 U/dL, time to achieve remission was the same 28,2 days. The titre inhibitor was significantly higher in the group with underlying disease (22 *vs* 3,5 BU/ml), and the rate of major bleeding was higher (86,7 *vs* 42,6%). At follow up of 31 months (1-71) 11 patients (73,3%) are alive, 4 (26,6%) dead. No death was due to bledding. Three (75%) of deaths was reported in a group of patients with underlying disease (two deaths associated with sepsis, one with progressive malignant disease) with mortality rate of 37,5 *vs* 14,2% on behalf of group with known cause of AHA. One death was associated with cardiogenic shock in patient without underlying disease of AHA. One patient (7%) had thrombotic complication (myocardial infarction and venous thromboembolism).
Summary/Conclusion: Mortality in patients with acquired haemophilia was associated with the underlying disease, cause of AHA (malignant disease), as well as with infective complications of immunosupresive treatment in elderly with comorbidites, according to recent literature data.

PB1808

COMPARISON BETWEEN ELISA BASED TEST FOR DETECTION OF FACTOR VIII ANTIBODIES SCREEN AND STANDARD BETHESDA

S. Bakr[1,2,*], R. Nasr[3], A.-K. Al-Momen[4], R. Al-Nounou[3], T. Owaidah[3]

[1]Department of Clinical Pathology, Faculty of Medicine, Fayoum University, Fayoum, Egypt, [2]College of Medicine, Princess Nourah bint Abdulrahman University, [3]Department of Pathology and Laboratory Medicine, King Faisal Specialist hospital and RC, [4]Center of excellence in Thrombosis and Hemostasis, College of Medicine, King Saud University, Riyadh, Saudi Arabia

Background: Inhibitors of Factor VIII (FVIII) which arise in up to 35% of patients with hemophilia A causing the most detrimental complications, are usually IgG polyclonal antibodies. Unluckily, the unavailability of the gold standard Bethesda assay that requires expertise in every hemophilia treating centers makes detection of anti FVIII antibodies seems difficult especially for low titer inhibitors.
Aims: To assess the efficacy of ELISA assay for detection of FVIII inhibitors in comparison to the Bethesda test.
Methods: A total of 102 patients with hemophilia A who were screened for inhibitors by APTT then confirmed by Bethesda assay, were tested using enzyme linked immune-sorbent assay (ELISA) for the presence of FVIII specific IgG antibody. Thirty control samples as well as negative and positive samples were included with each run.
Results: Out of all tested samples, 17 (16.7%) were positive by Bethesda assay. Nine samples had high titer (>10 BU), while 8 samples had low titer (<10 BU). In comparison between Bethesda test and ELISA, all the samples that were positive by Bethesda at both high and low titer were detected by ELISA test and all negative samples by Bethesda were also negative by ELISA. Only 6 samples that were positive by Bethesda but at very low titer (<1BU), were missed by ELISA.
Summary/Conclusion: This study results demonstrates strong correlation between the ELISA and Bethesda assay in detecting immune responses to FVIII, as what had been reported in previous literature. ELISA for FVIII antibody detection provides rapid screening test that could be available in small coagulation laboratory.

PB1809

CONTINUOUS INFUSION OF TUROCTOCOG ALFA DURING SURGERY: AN EFFECTIVE AND SAFE WAY OF TREATING PATIENTS WITH HAEMOPHILIA A

L. Koers[1,*], N. Uitslager[1], E. Mauser-Bunschoten[1], A. Huisman[2], I. Kremer Hovinga[1], P. van der Valk[1], R. Schutgens[1]

[1]Van Creveldkliniek, University Medical Centre Utrecht, Utrecht University, [2]Clinical Chemistry and Hematology, University Medical Centre Utrecht, Utrecht, Netherlands

Background: Turoctocog alfa (NovoEight®, N8) is a third generation recombinant factor VIII, developed for prevention and treatment of bleeding episodes in patients with haemophilia A.
Aims: To investigate the efficacy and safety of turoctocog alfa as continuous infusion (CI) peri-operatively in patients with haemophilia A.

Methods: Ten adult patients undergoing eleven surgical procedures were included in this retrospective, observational cohort study. Primary objective was the efficacy of turoctocog alfa via CI based on the stability of FVIII levels, blood loss during surgery and bleeding complications. Secondary objective was the safety of turoctocog alfa as CI, also in terms of blood loss and bleeding complications and in terms of *de novo* FVIII-inhibitor development. Dose was started at 4 U/kg/hr and adjusted daily based on FVIII levels. Target levels were predefined.
Results: Ninety-three percent of the achieved FVIII levels were equivalent to or higher than the target levels, with a mean deviation of 37% above target. All patients showed a higher *in vivo* recovery than expected, with a mean recovery of 0,029 IU/kg. All patients had an adequate perioperative haemostatic response. A change in treatment because of a bleeding complication was not required in any case. There were no thromboembolic complications. No new cases of FVIII-inhibitors were detected.

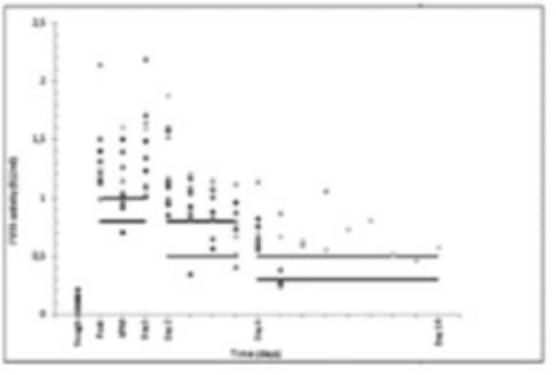

Figure 1.

Summary/Conclusion: Continuous infusion of turoctocog alfa is a feasible, effective and safe way of treating patients with haemophilia A during surgery.

RETROSPECTIVE EVALUATION OF ACQUIRED HEMOPHILIA IN A SPANISH CENTER

F. Martín Moro*, E. Arrontes Caballero, C. Guillén Rienda, I. García García, B. Michael Fernández, C. Martínez-Geijo Román, K. Velázquez Kennedy, A. Sanz Rupérez, J. Marquet Palomanes, F.J. López Jiménez

Hematology and Hemotherapy, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: Acquired hemophilia (AH) is a rare autoimmune bleeding disorder caused by the development of an autoantibody directed against a coagulation factor, most frequently factor VIII (FVIII).
Aims: To review the characteristics and management of AH in our center during the last five years (2013-2017).
Methods: Retrospective single-center study. There is no Department of Obstetrics in our hospital. Data was collected from clinical records.

Table 1. Summary of the 7 patients who received treatment to eradicate FVIII inhibitor.

**Relapse; **no plasmapheresis; ***GTH-AH 01/2010. CMV: Cytomegalovirus; CS: Corticosteroids; CTX: Cyclophosphamide; IFI: Invasive Fungal Infection; MBMP: Modified Bonn-Malmö Protocol; NA: Not Available.*

Results: Eleven patients were found: 10 with FVIII inhibitor and 1 with FXI inhibitor. Of the 10 patients diagnosed with AH A (4M, 6F), 1 was a relapse. The median age at diagnosis was 85 years (76-93). Median time to diagnosis from symptom onset was 1 month (0.4-18). Underlying disease: autoimmune (4), solid neoplasia (3), hematologic neoplasia (2) and idiopathic (1). All cases had bleeding as initial presentation (one life-threatening): subcutaneous (6), genitourinary (3), muscle (1), gastrointestinal (1) and/or after surgery (1). All patients had anaemia at diagnosis. FVIII level at diagnosis was<5% in most cases (8/10), the median inhibitor level was 64 BU (1.4-134). Regarding treatment, 3 patients received Corticosteroids alone due to comorbidities, without follow-up; 3/3 died due to underlying disease/unknown cause. The remaining 7 patients were treated to eradicate FVIII inhibitor (Table 1). Recombinant FVII activated was chosen as first-line haemostatic agent. Bleeding stopped in all cases and none presented thrombosis. Three of these 7 patients passed away, 2 due to underlying disease/unknown cause and 1 due to immunosuppression. The patient with acquired FXI inhibitor was a 73 year-old female with no underlying disease. No bleeding at diagnosis. The first-line of eradicator treatment was CS + CTX, then second-line Rituximab, without response. She passed away due to immunosuppression-related complications.
Summary/Conclusion: All patients were elderly at diagnosis, influenced by the lack of pregnancy-associated cases. An underlying disease was found in almost all cases. In our experience all patients with FVIII inhibitor who received eradicator treatment achieved a response (partial +/- complete). Treatment with higher immunosuppression involved more complications. Most deaths were due to underlying disease/unknown cause.

THE ASSOCIATION BETWEEN HLA CLASS I,II ALLELES AND THE OCCURRENCE OF INHIBITOR IN TURKISH PATİENTS WITH HEMOPHILIA A: A PILOT STUDY

T. Patiroglu[1,*], M. Cansever[2], S. Akbayram[3], H. Gulen[4], K. Oncel[5], O. Bor[6], Y. Oymak[7], Y.Z. Aral[8], Y. Ay[9], R.K. Kavaklı[10], H. Oren[11], Y. Kılınç[12]

[1]Pediatric Hematology, [2]Pediatric Immunology, Erciyes University Medical Faculty, Kayseri, [3]Pediatric Hematology, Gaziantep University Medical Faculty, Gaziantep, [4]Pediatric Hematology, Celal Bayar University, Manisa, [5]Pediatric Hematology, Ankara Unıversty, Ankara, [6]Pediatric Hematology, Osmangazi Unıversty, Tokat, [7]Pediatric Hematology, Gazi Unıversty, Ankara, [8]Pediatric Hematology, Adnan Menderes Unıversty, Aydın, [9]Pediatric Hematology, Behçet Uz Research Hospıtal, [10]Pediatric Hematology, Ege Unıveresty, [11]Pediatric Hematology, Dokuz Eylül Unıversty, [12]Pediatric Hematology, Dokuz Eylul Universty, İzmir, Turkey

Background: Inhibitor is the most severe complication of hemophilia A treatment. Approximately, antibodies against Factor VIII develop in 25% of severe hemophilia A patients. There are both genetic and enviromental factors contributing the development of inhibitor. Genetic factors include Factor VIII gene defects (deletion of intron 22),and polymorphisms of immune response genes including genes encoding the human leukocyte antigens, tumor necrosis factor-a (TNF-a), interleukin-10 (IL-10) and cytotoxic T-lymphocyte antigen-4 (CTLA-4). It has been shown the association with some HLA alleles and inhibitor against Factor VIII.
Aims: The purpose of the pilot study is to evaluate the frequencies of HLA class I (A, B, C) and class II (DRB1, DQB1) alleles in patients with Turkish hemophilia A and compare to the results of unrelated healthy controls.
Methods: The distribution of HLA class I and II alleles in 30 hemophilia A patients with inhibitor and 30 unrelated healthy subjects as controls was determined using the PCR- Sequence Based Typing (PCR-SBT) method, and the association between the occurrence of factor VIII (FVIII) inhibitor and the presence of certain HLA class I and II alleles was investigated.
Results: The frequency of HLA-DQB1*02:02 was significantly higher in the hemophilia A patients with FVIII inhibitor as compared to controls (p=0.029). On the contrary, HLA-C*08:02, HLA-DRB1*03:01, and HLA-DRB1*04:02 alleles frequencies lower than controls (p=0.014, p=0.029, and p=0.014, respectively).
Summary/Conclusion: The study's findings show that the DQB1*02:02 allele might have contributed to the occurrence of inhibitor in hemophilia A patients; however, additional research using larger samples is warranted.

PB1812

CYTOKINE ADSORPTION IN A PATIENT WITH SEVERE COAGULATION ABNORMALITIES DUE TO HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS (HLH)

S. Birndt[1,*], S. Fetscher[2], M. Frimmel[3], A. Hochhaus[1], P. La Rosée[4]

[1]Klinik für Innere Medizin II, Universitätsklinikum Jena, Jena, [2]Medizinische Klinik III, [3]Interdisziplinäre Intensivmedizin, Sana Kliniken, Lübeck, [4]Medizinische Klinik II, Schwarzwald-Baar-Klinikum, Villingen-Schwenningen, Germany

Background: Hemophagocytic lymphohistiocytosis (HLH) is a hyperinflammatory syndrome evolving from a pathologic immune response, leading to

uncontrolled cytokine release and organ damage. In adults, HLH can be triggered by various conditions like infections, malignancies, or autoimmune diseases. HLH treatment is based on immunosuppression and trigger directed therapies. However, despite improved treatment protocols, patients with severe HLH still have a poor prognosis. Cytokine adsorbing devices are increasingly used in treating critically ill patients with inflammation and hypercytokinemia to prevent and reduce the effects of pro-inflammatory cytokines[1]. Thus, cytokine adsorption may be a suitable therapeutic option in severe, life-threatening HLH.
Aims: We report the case of a 49-year old male patient presenting with severe coagulation abnormalities due to hemophagocytic lymphohistiocytosis.
Methods: Case report. A 49-year old male patient was admitted to intensive care unit (ICU) because of suspected sepsis. A prodromal two week episode had led to previous emergency room admissions due to fever of unknown origin (FUO). We began fluid replacement therapy and started empiric antibiotic treatment with piperacillin/tazobactam, leading to initial improvement of the patients clinical condition. However, pancytopenia progressed and coagulation parameters deteriorated to unmeasurable levels (fibrinogen 0.31 g/l [reference range 1.8-3.5], INR >8) making large scale substitution treatment necessary. Despite extensive diagnostics, no infectious focus was found. Indicated by markedly elevated ferritin values (81,393 µg/l), HLH was diagnosed with 7 of 8 HLH-2004 criteria. A combination therapy using dexamethasone, polyvalent immunoglobulins and etoposide was administered without improvement of coagulation parameters. Due to progressive multiple organ failure (respiratory/renal/hepatic/hematopoietic) we initiated cytokine adsorption using Cytosorb columns in serial application with continuous hemofiltration. In marked association with cytokine adsorption, coagulation features significantly improved and inflammatory markers decreased. Multiple organ failure reversed and the patient was moved to the general ward.
Results: Overall, hemoadsorptive treatment was performed over 12 days. Cytokine adsorption resulted in a substantial decline of C-reactive protein and interleukin-6. Using immunosuppression and hemoadsorption, coagulation slowly improved. Moreover, ferritin and lactate dehydrogenase levels decreased, whereas no effect on soluble interleukin-2 levels was observed. Utilization of the cytokine adsorber was safe and well-tolerated, and no relevant side effects were noticed. No HLH-triggering disease was identified. Functional tests including degranulation assays and perforin expression were within normal range. Currently, the patient is in follow-up one year after initial HLH diagnosis with tapered immunosuppressive treatment.
Summary/Conclusion: HLH treatment remains challenging as multiple organ systems can be affected. Besides immunosuppression and trigger specific therapies, cytokine adsorption is a useful tool in imminent or present multiple organ failure, when drug treatment intensification is limited by organ function.

UNIQUE CASE OF TYPE 3 VON WILLEBRAND DISEASE

M. Mandava[1,*], S. Bergmann[1], E. Curl[2], J. Lazarchick[3]

[1]Pediatric hematology oncology, [2]Departmen of pathology, [3]Department of Pathology, medical university of South carolina, charleston, United States

Background: VonWillebrand disease (vWD) is the most common inherited bleeding disorder worldwide. Genetic mutations in the von Willebrand gene may result in either quantitative (Types 1 and 3 vWD) or qualitative defects (Type 2 vWD) of von Willebrand Factor (vWF), which plays a major role in hemostasis. Type 3 is the rarest and most severe form of vWD, resulting in a virtual absence of vWF. Type 3 vWD follows autosomal recessive inheritance and is most often reported in patients who are homozygous for the same gene mutation.
Aims: We report a case with type 3 vWD inheriting two different mutations, one from each parent, resulting in compound heterozygosity.
Methods: Array Comparative Genomic Hybridization (aCGH)/Duplication analysis was performed on our patient sample. Family was tested by PCR amplification and bi-directional DNA sequence analysis of requested exons.
Results: Our patient presented with a normal CBC and normal levels of Factor IX, XI, and XII activity. Her PTT was prolonged at 59 (reference range 23.3-35.7) with a normal INR. A von Willebrand panel showed markedly decreased Factor VIII (2%), vWF antigen (6%), and vWF activity (8%). VWF multimers were absent, consistent with a diagnosis of type 3 vWD. VWF gene sequence analysis was sent to the Blood Center of Wisconsin and demonstrated two pathologic variants, one on each allele: c2345delC in exon 18 and a deletion within exon 6. Subsequent analysis revealed that the patient's mother is heterozygous for the c2345delC variant and the patient's father is heterozygous for the deletion within exon 6 of the VWF gene. The patient's older sibling inherited only the maternal mutation, resulting in a diagnosis of Type 1 vWD, and a younger brother was negative for both mutations.
Summary/Conclusion: Type 3 vWD is quite rare, with a prevalence ranging from 0.1-5.3 per million. Our case is especially interesting due to the unique inheritance pattern resulting in our patient's type 3 vWD phenotype. Type 3 vWD cases are most often described in patients homozygous for a mutation in the VWF gene, frequently as a result of consanguinity. Our patient inherited a unique variant from each parent, resulting in heterozygous expression of two defective VWF alleles (compound heterozygosity). In our patient's family, because each parent is heterozygous for a mutation in the VWF gene, future children have a 75% chance of inheriting at least one mutation, and a 25% chance of inheriting both mutations. Type 3 vWD patients have impaired endogenous synthesis of functional vWF, thus therapies such as desmopressin, used in other types of vWD to stimulate secretion of endogenous vWF, are ineffective. Instead, first-line treatment in Type 3 is replacement therapy with Humate-P as needed during bleeding episodes and/or as prophylaxis. Humate P is VWF/FVIII concentrate is obtained from pooled human plasma from many carefully screened plasma donors and contains the clotting proteins VWF and FVIII. Humate-P has a VWF:FVIII ratio of approximately 2.4:1. Adjuvant treatment with fibrinolytic agents has been attempted in some patients, and platelet transfusions have been administered in patients with excessive bleeding despite first-line treatment, with some success. Complications of therapy include the rare development of anti-vWF alloantibodies, which most often occurs in patients with partial or complete VWF gene deletions. Our patient has received aminocaproic acid for minimal bleeding episodes and plasma derived vWF/FVIII concentrates for multiple episodes of moderate bleeding. She has not developed antibodies, but is at high risk.

PB1814

CLINICAL FEATURES AND TYPES OF VON WILLEBRAND DISEASE IN WOMEN WITH MENORRHAGIA REFERRED TO HEMATOLOGY CLINIC OF KERMANSHAH

M. Aeinfar*, M. Payandeh

KUMS, KUMS, Kermanshah, Iran, Islamic Republic Of

Background: Menorrhagia is the most common symptom that is experienced by women with bleeding disorders. Von Willebrand disease (VWD) is the most common congenital human bleeding disorder that is manifested as a quantitative deficiency in Von Willebrand factor (VWF) or dysfunction of this factor.
Aims: The present study was carried out to find the frequency of VWD, its types, and clinical features of the disease among women with menorrhagia who referred to the Hematology Clinic of the Kermanshah University of Medical Sciences.
Methods: Case study
Results: The study comprised 482 women with menorrhagia. After excluding patients with confounding factors, 56 (11.6%) patients were evaluated for inherited bleeding disorders. We detected 31 (55.3%) patients with VWD. Type 3 of VWD was the most frequent subtype (45.1%) followed in frequency by type 2, (32.2%), and type 1 (22.5%).
Summary/Conclusion: In conclusion, our study indicated that menorrhagia can be the first symptom of VWD. Therefore, rare coagulation disorders should be considered in women with idiopathic menorrhagia, particularly in regions with high rates of consanguinity.

PB1815

KOREAN VON WILLEBRAND DISEASE REALITIES

S.K. Park[1,*], S.K. Kim[2], J.H. Seol[1]

[1]Pediatrics, Ulsan University Hospital, Ulsan, [2]pediatrics, inha univ hospital, Incheon, Korea, Republic Of

Background: von Willebrand disease (VWD) is the most common inherited bleeding disorder with a prevalence of up to 1%. However in Korea, only 126 VWD patients were registered in Korea Hemophilia Foundation (KHF).
Aims: The aim of this study was to determine the status of VWD patients in Korea. We analyzed VWD patients by age, gender, blood group, family history and bleeding history.

Methods: One hundred twenty-six VWD patients registered in the KHF by December 2016, and 74 patients diagnosed at six university hospitals were enrolled in this study. We evaluated the medical records from the KHF and the questionnaires from six university hospitals retrospectively.
Results: Seventeen patients misdiagnosed and ten patients duplicated were excluded. One hundred nine patients registered in the KHF and 64 patients diagnosed at six university hospitals met the criteria for VWD. The blood type O accounts for 72 (51.8%). VWF mutation was detected in 30 patients (17.3%). Median age at diagnosis was 10.5yr. The bleeding score of adults was higher than that of children (P 0.001). The most common bleeding symptom was epistaxis (48.5%). The distribution of VWD types was: 67% of type 1, 30.1% of type 2, and 2.9% of type 3.
Summary/Conclusion: Even though only six hospitals responded to the survey, 64 patients not registered in the KHF were diagnosed with VWD. Our results suggest the prevalence of Korean VWD might be higher than previously reported. A nationwide registration system is warranted in order to accurately identify the national prevalence of VWD.

PB1816

TRAINING THE PATENT AND PARENTS IN SELF-ADMINISTERING THE MISSING BLOOD FACTOR AT HOME

P. Laguna*, M. Matysiak

Ped Hem/Onc, Medical University, Warsaw, Poland

Background: Since 2008 all patients with severe forms of haemophilia A and B aged 0-18 have been included in the programme of prophylactic administration of the missing factor.
Aims: The programme consists of: ensuring the availability of the factor, delivering the factor to patients homes and collecting the waste after the procedure. In order to improve the independence of patients and their families, since 2014 qualified nurses have been educating and instructing them how to self-administer the factor intravenously and to central venous catheters. Such training take place throughout Poland.
Methods: Materials and Methods Two nurses, who were employed by the Shire company, at the request of a physician and after receiving parental consent, performed the training at patients houses where they showed how to apply the missing factor using. There were 560 dummies educational visits. Another role of these nurses was to train medical staff and staff in schools close to the patients' places of residence.150 training sessions took place (45 of them took place in schools and 105 in hospitals). In addition, those nurses also took part in conferences about haemophilia intended for patients and medical staff.
Results: Results The quality of life of our patients has significantly improved since introducing such training. Self-administering the missing factor by parents or even patients themselves is not a problem anymore. As a result of participating in the training, our patients became more independent and level-headed.
Summary/Conclusion: The training of self-administering the missing factor by patients and parents, as well as by teachers and medical staff close to the patients' places of residence is an important part of improving the quality of their lives

PB1817

HEMOPHILIA CARE IN PAKISTAN

M. Borhany*, N. Fatima, M. Abid, T. Shamsi

National Institute of Blood Disease and Bone Marrow Transplantation, Karachi, Pakistan

Background: Hemophilia is a rare congenital disorder characterized by prolonged bleeding, either spontaneously, or after injury. In the developing world, where majority of the hemophiliacs live, awareness of this disease and its management is poorly done. It is a significant cause of morbidity and mortality and is responsible for psychological, social and economical stress to patients and their families.
Aims: The objective of this study was to evalute the frequency of Hemophilia patients diagnosed among bleeding disorders, their demographics and treatment options available for patients with hemophilia in countries with limited resources.
Methods: This is a cross sectional, observational study was carried out at the National Institute of Blood Disease Karachi, Pakistan after getting approval from the Institutional ethics committee. Diagnosed adult and pediatric hemophilia A (HA) and hemophilia B (HB) patients of various ages and severity were included from 2012-2017. Demographic and management history of hemophila patients were recorded and analyzed.
Results: A total of 149 male patients diagnosed as HA (n=107) and HB (n=42) were evaluated. Mean age of HA 13.1±10.6 and for HB is 15.1±11.1 years. Age at diagnosis ranged from birth to 3 years. History of consanguinity was present in 85% of cases and significant family history of bleeding in 69% of patients. Hemarthrosis and hematoma were the more frequent symptoms in these patients. Surgical history including circumcision was done in 55%patients while 4 had major surgeries (hip& femur bones fracture, extensive nasal septum, and head surgery). 29% of patients had transfusion-transmitted infections in which HCV (68%) was most prevalent followed by HBV (11%) and HIV (4%). 14 HA patients (13%) were found to have positive results for inhibitors and none in HB. Treatment included tranexamic acid, fresh frozen plasma, cryoprecipitate, cryosupernatant and factor concentrates on demand basis. Recently we have started low dose prophylaxis regimen for 15 children<10 years old with the help of World Federation of Hemophilia. We administer 250 IU vial once a week and monitor for bleeds. If no bleed, continue same dose. If 2-3 joint bleeds occur in 3 months, increase the dose to twice weekly and treat the bleed (20-30 IU/kg).
Summary/Conclusion: Hemophilia A and B are common among congenital bleeding disorders. Rate of transfusion-transmitted diseases, particularly hepatitis C infection, has gained a huge proportion. Comprehensive haemophilia care center with multidisciplinary approach needs to be established.

PB1818

A RARE CASE OF ACQUIRED HEMOPHILIA A INDUCED BY THE USE OF RIVAROXABAN

C. Freitas De Andrade Rodrigues[1,*], M.T. Hercos Juliano[2], I. Marinho de Azevedo[2]

[1]Hematology, [2]Cardiology, Hospital Universitário-Ufma, Sao Luis, Brazil

Background: Rivaroxaban is an anticoagulant and the first orally active direct factor Xa inhibitor. It is indicated for the prevention of venous thromboembolic events, especially stroke and systemic embolism in patients with nonvalvular atrial fibrillation. Routine lab monitoring is not necessary. At advanced age, hemorrhage may become a serious side effect of anticoagulants and it must be investigated to exclude other causes of acquired coagulopathies. One of these is Acquired Hemophilia A (AHA), a rare bleeding disorder caused by an autoantibody to coagulation factor VIII. It is characterized by soft tissue bleeding in patients without a personal or family history of bleeding. Bleeding is variable, ranging from acute with up to 22% mortality to mild bleeding that requires no treatments. Initial treatment involves the control of acute bleeding with bypassing agents. Immunosuppressive treatment to eradicate the FVIII inhibitor should be started as soon as the diagnosis is confirmed to reduce the time the patient is at risk of bleeding.
Aims: Report a rare case of a patient taking rivaroxaban with bleeding associated with acquired hemophilia A.
Methods: We report a case of a 72-year-old man suffering from atrial fibrillation/coronary, artery disease/ hypertension for several years and taking Rivaroxaban 20mg/24h since 2014. He presented at an emergency with genital urinary and muscle bleedings specially in hands and abdomen.
Results: Hemostatic tests indicated prolonged activated partial thromboplastin time (APTT) to 107 sec (norm 26-36 sec), normal value of the prothrombin index which was 85% (norm 70-130%), fibrinogen concentration to 380 (normal value 200-400 mg/dl), the bleeding time was 5 min (norm<10 min) and the platelet count was 325 x 10^9/l (norm 130-400 x 10^9/l). Therapy with Rivaroxaban was discontinued. 48 hours later the patient presented the same alterations in exams. A coagulation disorder was therefore suspected. The autoantibody against factor VIII in a titer 205 Bethesda Units/ml (BU/ml) and decreased factor VIII activity to 0,1% (norm 50 -150%) with normal plasma concentration of factor IX. Activated (FEIBA, Baxter) had been used in the treatment of bleeding episodes for five times. immunosuppressive treatment with oral prednisone 80mg/24h was administered for three weeks without improvements. Then, cyclophosphamide 100mg/24h was added in order to remove the factor VIII inhibitor. One month later, APTT decreased to 57 sec but little bleedings continued. We decided to use Rituximab 375 mg/m^2 weekly for four doses. After this, reduction of the factor VIII inhibitor titer to 2,6% and increased of factor VIII activity to 128% led to normalization of hemostatic parameters. We investigated solid tumors and lymphoproliferative diseases by using computerized tomography, PET scan and tumor markers which were negative. Autoantibodies to rheumatologic diseases were negative.
Summary/Conclusion: Although the new anticoagulants are safe, hemorrhages may occur and clinicians should conduct these alterations carefully. Delay or undertreatment may be life-threatening. If atypical hemorrhage occurs during anticoagulant therapy, *e.g.* severe nontraumatic skin hemor-

rhage, an additional coagulation disorder should be considered. In order to confirm diagnosis, clotting testing can be performed again 48 hours after anticoagulant treatment is interrupted. If APTT, for example, remains abnormally prolonged, clotting disorders such as deficiency of clotting factors VIII, IX, or XI should be ruled out.

PB1819

5Q35.2Q35.3 MICRODUPLICATION ENCOMPASSING NSD1 WITH UNEXPLAINED PANCYTOPENIA: CASE REPORT

S. Park[1,*], G.-W. Lee[2], H.-N. Song[1]

[1]Gyeongsang National University Hospital, Jinju, Korea, Republic Of, [2]hemato-oncology, Gyeongsang National University Hospital, Jinju, Korea, Republic Of

Background: Variety of diseases, haematological and non-haematological can affect the bone marrow primarily or secondarily, resulting in pancytopenia. But the incidence of pancytopenia with normal bone marrow was 3.38% to 10.5% in various international studies. Meanwhile, Sotos syndrome is an autosomal dominant childhood overgrowth syndrome with additional features of characteristic dysmorphisms, mild-to-severe learning disabilities (LD) and advanced bone age. As, in contrast, the duplication 5q35.2.q35.3 phenotype is characterized by growth delay, microcephaly and delayed bone age in some patients, it has been referred to as a reversed Sotos phenotype. However, there has been no report on the occurrence of pancytopenia as duplication 5q35.2.q35.3 phenotype.

Table 1.

Table 1. Haematological parameters of the patient during the stay in hospital

Parameters	3rd day	9th day	24th day	40th day	51th day	65th day
Hb(gm/dl)	8.6	6.9	10.2	7.3	10.7	12.7

platelet(cells/cumm)	71,000	2,000	51,000	1,000	70,000	2,000

Abbreviation: Hb, hemoglobin; TLC, total leucocyte count; ANC, absolute neutrophil count

Table 2. Evaluation of the pancytopenia

Infectious disease	
Parvo B19 virus	negative
HIV	negative
HBV	negative
HCV	negative
CMV	negative
EBV	negative
Immunology	
ANA	negative
ANCA	negative
RF	negative
Cold agglutinin	negative
Direct/indirect coombs	negative
Other	
Vitamin B12 (pg/mL)	>2000.0
Folate (ng/mL)	>20
PNH screen	negative
Fanconi test	negative
Gaucher test	negative
Chromosomal Karyotype	46, XY, t(6;9) (q21;q21)

Abbreviation: HIV, human immunodeficiency virus; HBV, Hepatitis B virus; HCV, Hepatitis C virus; CMV, cytomegalovirus; EBV, Epstein-Barr virus; ANA, antinuclear antibody; ANCA, Anti-neutrophil cytoplasmic antibody; RF, Rheumatoid Factor; PNH, paroxysmal nocturnal hemoglobinuria

Aims: We report the a 42-year-old male patient who has the microduplications of 5q35.2-q35.3 including NSD1 with unexplained pancytopenia was not improved by any treatment, but experienced no serious complications.
Methods: A 42-year-old male visited emergency room due to multiple trauma. He was diagnosed with mental retardation in the past. Physical examination was unremarkable except tenderness from bone fracture. Peripheral blood test showed leukocyte 3,510/mm^3, neutrophil 190/mm^3, hemoglobin 8.3 g/dL, hematocrit 25.0% and platelet 4,000/mm^3. There was no relevant history of intake of any medications and exposure to radiation. And there were no other haematological parameters to lead pancytopenia. The finding of bone marrow biopsy was hypercellular marrow with trilineage hematopoiesis. The fluorodeoxyglucose (FDG) uptake increased in multiple lymph node, bone and spleen in positron emission tomography–computed tomography (PET-CT) and lymph node biopsy was undergone in right axilla, but histologic finding was unremarkable. The chromosomal study in bone marrow showed 46 XY, t (6:9) (q21;q21) and the microarray revealed a gain of about 3.5 Mb at the 5q35.2q35.3 site including NSD1.
Results: Any treatments including vitamin and folic acid supplement, platelet transfusion, granulocyte colony-stimulating factor, steroid and intravenous immunoglobulin had no effects in the patient. But there were no severe complications associated with pancytopenia during a follow-up of 3 months. And periodic pattern of deterioration and improvement appeared in pancytopenia, spontaneously.
Summary/Conclusion: Since it is rare for these distinctive feature of pancytopenia and chromosomal abnormality to coexist together, it is necessary to investigate the association. We describe the first case of 5q35.2q35.3 microduplication encompassing NSD1 with unexplained pancytopenia. Molecular cytogenetic testing in individuals with unexplained pancytopenia could led to the discovery of new phenotype of 5q35.2q35.3 microduplication syndromes.

PB2545

ANALYSIS OF ANTI-THROMBOPOIETIN RECEPTOR ANTIBODYIES IN PATIENTS WITH IMMUNE THROMBOCYTOPENIA

T. Satoh[1,2,*], K. Miyazaki[3], R. Horie[1,2]

[1]Division of Hematology, Kitasato University School of Allied Health Sciences, [2]Division of Molecular Hematology, Kitasato University Graduate School of Medical Sciences, [3]Department of Transfusion and Cell Transplantation, Kitasato University School of Medicine, Sagamihara, Japan

Background: Immune thrombocytopenia (ITP) is an autoimmune disease characterized by the presence of autoantibodies against platelet membrane glycoproteins, such as GPIIb/IIIa. An *in vitro* study showed that plasma containing anti-GPIIb/IIIa antibodies from adults with severe ITP inhibited the maturation of hematopoietic stem cells into megakaryocytes. In addition, some patients with ITP had anti-thrombopoietin receptor (TPOR) antibodies that suppressed megakaryocyte differentiation. Eltrombopag is a TPOR agonist that increases platelet counts by stimulating the differentiation and proliferation of megakaryocytes in ITP.
Aims: To determine the prevalence and pathogenic role of anti-TPOR antibodies in Japanese patients with ITP.
Methods: Anti-TPOR antibodies from 132 patients with ITP and 70 healthy controls were measured by enzyme-linked immunosorbent assay (ELISA). TPO levels in platelet-poor plasma were measured using an ELISA kit. To investigate whether anti-TPOR antibodies inhibited functional interactions between TPO and TPO receptors, we examined extracellular signal-regulated kinases (ERKs), downstream signals induced by recombinant human TPO (rhTPO). The binding of rhTPO to TPO receptors induced the phosphorylation of ERK in TPOR-expressing UT-7/TPO cells. Furthermore, for functional analyses, eltrombopag was used instead of rhTPO.
Results: Anti-TPOR antibodies were detected in fifteen ITP patients (11.4%) and none of the healthy controls. There was no difference in plasma TPO levels between ITP patients with anti-TPOR antibodies and patients without anti-TPOR antibodies (77.5±78.7 pg/ml versus 52.7±57.4pg/ml). Six of 10 anti-TPOR antibody-positive samples inhibited the phosphorylation of ERK in UT-7/TPO cells, which might be related to the blocking of rhTPO by anti-TPOR antibodies. In contrast, healthy control and anti-TPOR antibody-negative samples had no inhibitory effect. Eltrombopag improved the phosphorylation of ERK in UT-7/TPO cells in the presence of functional anti-TPOR antibodies.
Summary/Conclusion: Our findings suggest that functional anti-TPOR antibodies impair megakaryocyte differentiation and proliferation in patients with ITP. Eltrombopag might be a therapeutic option for ITP patients with anti-TPOR antibodies.

EPIDEMIOLOGICAL, CLINICAL AND GENETIC CHARACTERIZATION OF APLASTIC ANEMIA PATIENTS IN PAKISTAN

Z. Akram[1,2,3,*]

[1]Department of Hematology, National Heart, Lung and Blood Institute, NIH, Bethesda, United States, [2]Biochemistry, Quaid i Azam University,, Islamabad, [3]Stem Cell Research Lab, Armed Forces Bone Marrow Transplant Centre, rawalpindi, Pakistan

Background: Aplastic anemia (AA) is a rare and life threatening hematopoietic disease characterized by peripheral blood pancytopenia accompanied with trilineage bone marrow (BM) aplasia. AA may develop at any stage of lifeAccording to epidemiological studies, the estimated annual incidence of AA is two per million in Western countries. The incidence rate is 2-3 times higher in Asian population but the cause for this is still not clear. In Pakistan, AA is the second most common serious non-malignant blood disorder after thalassemia. AA has been reported predominantly in young adult male population.
Aims: To gain insight into the genetics and pathophysiology of AA in the Pakistani population, we investigated samples from AA patients reporting at the Armed Forces Bone Marrow Transplant Centre, Rawalpindi, Pakistan. This is the first study where examination of socio-etiological data, cytokine profiling, HLA allelic association and mutations in *TERT* and *TERC* genes were simultaneously studied to dissect a high incidence of AA cases in Pakistani population.
Methods: Genomic DNA (gDNA) was extracted from whole blood and peripheral blood mononuclear cells (PBMCs) of AA patients using the DNeasy Blood and Tissue kit (Qiagen, Valencia, CA, USA).For mutation analysis, polymerase-chain-reaction (PCR) amplification of *TERT* and *TERC* genes was performed.Purified PCR products were subjected to direct sequencing with the BigDye Terminator v3.1 Cycle Sequencing kit (ThermoFisher Scientific, Waltham, MA, USA) and the 3130*xl* Genetic Analyzer (ThermoFisher Scientific). Serum cytokine levels were measured by Magnetic Luminex Screening Assay using the Human Premixed Multi-Analyte kit. HLA typing was carried out in 74 of our patients by PCR with sets of sequence specific primers (SSP) or serological technique.The descriptive statistics were performed using SPSS version 17.0. GraphPad PRISM software version 6 was used for analysis of variance using Krusk-Wallis test to compare serum levels of cytokines, growth factors and hormones between different patient groups and control subjects. A P value<0.05 was considered statistically significant.
Results: Epidemiological data revealed 2.75-fold higher frequency of AA among males. A single peak of disease onset was observed between age 10-29 years followed by a steady decline. AA was strongly associated with lower socioeconomic profile, rural residence and high rate of consanguineous marriages. Serum G-CSF and TPO levels were significantly elevated in AA patients, compared to healthy controls (P<0.001), while there was no statistical significance in other nine cytokine levels screened. Allele frequencies of DRB1*15 (56.8%) and DQB1*06 (70.3%) were predominantly high in AA patients. Ten mutations were found in TERT and TERC genes, including two novel mutations (Val526Ala and Val777Met) in exon 3 and 7 of TERT gene.
Summary/Conclusion: Despite specific features of the AA cohort, this study suggests that epidemiologic and etiologic factors as well as host genetic predisposition exclusively or cooperatively trigger AA in Pakistan.

PB1821

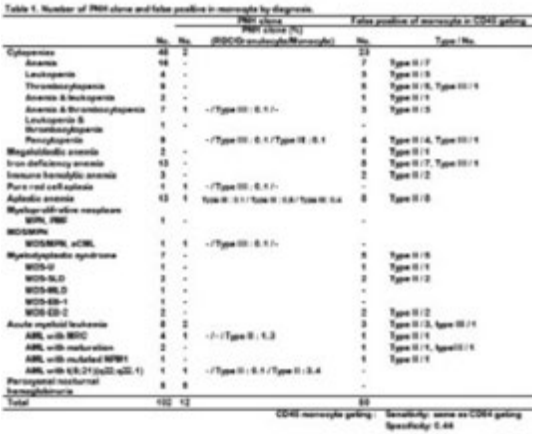
HOW USEFUL IS CD14 AND CD64 FOR GATING MONOCYTES IN FLOW CYTOMETRIC STUDY FOR PROXIMAL NOCTURNAL HEMOGLOBINURIA?

W.-J. Kwoun*, J.-Y. Ahn, P.-W. Park, Y.-H. Seo, K.-H. Kim, J.Y. Seo, J.-H. Jeong, H.T. Lee

Laboratory Medicine, Gachon University Gil Medical Center, Incheon, Republic of Korea, Incheon, Korea, Republic Of

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare hematopoietic stem cell disorder acquired by somatic mutation of phosphatidylinositol glycan–class A (PIG-A) gene. PIG-A mutation leads partial or absolute defect in expression of GPI-anchored cell surface structure, and this result in episodes of intravascular hemolysis that are typical of the disease. Flow cytometric techniques with utilizing the FLAER enable to sensitive identify very small numbers of GPI-deficient cells. Flow cytometric PNH testing uses CD15 to gate on neutrophils, and recently uses CD64 to gate on monocytes.
Aims: In this study, we investigate utility of CD14 and CD64 in PNH study of monocyte by compare with CD45 gating in PNH study of all cytopenia cases including underlying hematologic malignancy.
Methods: Total 102 PNH study cases were recruited from July 2017 to February 2018 at Gachon University Gil Medical Center in Korea. The PNH study was done on EDTA blood specimens. Two tubes of whole blood were stained for white blood cells with two combinations consisting of FLAER and CD45 with CD15, CD24 and CD64, CD14 to gate on granulocyte and monocyte, respectively. The sample was analyzed on Cytomics FC500 cytometer. Monocyte proportions were estimated in two ways, one is gating monocyte region in CD45 plus light scatter plot and the other is gating monocyte region in CD64 plus CD14 scatter plot. Reference monocyte proportions were measured by ADVIA 2120i using samples collected together with PNH study sample. Statistical analysis of result with Bland-Altman plot was done with medcalc 15.2.
Results: Prominent PNH clone of RBCs, granulocytes and monocytes were identified in 5 cases and minor PNH clones population were detected in 7 cases. 36 cases were undergoing bone marrow biopsy and 17 cases were diagnosed as hematologic malignancy including myelodysplastic syndrome and acute leukemia. Minor PNH clones are identified in 3 hematologic malignancy cases. Aplastic anemia diagnosed in 13 cases, minor PNH clone was detected in one case. CD45 monocyte gating method showed 50 false positive cases. False negative case was not found in this study (Table 1). Compare with CD64 monocyte gating result, specificity of CD45 gating is 0.44 and sensitivity is same as CD64 gating. Difference between reference and CD45 gated monocyte proportion was 105.57(%) with 35.48 standard deviation(SD). Difference between reference and CD14 plus CD64 gated monocyte proportion was 15.87(%) with 36.11 SD.

Table 1.



Summary/Conclusion: Flow cytometry allow to detect GPI-deficient PNH phenotype highly sensitive. Adding appropriate monocyte specific lineage markers, such as CD14 and CD64, for gating monocyte result in reduce difference of monocyte proportion between reference method and increases accuracy of monocyte gating. Specificity of detecting PNH clones also increased compare. All 50 false positive samples show single normal monocyte population when tested with CD14 plus CD64 monocyte gating method. Minor PNH population was also detected in CD45 gating method when detected by CD14 plus CD64 gating method. Percentage of type in each minor PNH clone was not much different by gating method. However, Case with prominent PNH clone, proportion of Type III monocytes were less in CD14 plus CD64 gating than CD45 gating, and show more clear population. CD14 and CD64 are useful in PNH study for monocytes detect and identify a small amount of PNH clone, thus these two markers are worthy to include in routine PNH study.

Bone marrow failure syndromes incl. PNH – Clinical

A COMPARISON OF THE ACCURACY IN DETECTING MINOR PNH CLONES IN PATIENTS WITH BONE MARROW FAILURE BETWEEN TWO HIGH-SENSITIVITY FLOW CYTOMETRY ASSAYS: CLSI AND OPTIMA

K. Hosokawa[1,*], K. Ishiyama[1], T. Ikemoto[2], C. Sugimori[3], H. Noji[4], T. Shichishima[4], N. Obara[5], S. Chiba[5], H. Ninomiya[5], Y. Shirasugi[6], Y. Nakamura[6], K. Ando[6], Y. Ueda[7], Y. Yonemura[8], T. Kawaguchi[8], J.-I. Nishimura[7], Y. Kanakura[7], S. Nakao[1]

[1]Kanazawa University, Kanazawa, [2]Osaka Medical College, Takatsuki, [3]Ishikawa Prefectural Central Hospital, Kanazawa, [4]Fukushima Medical University, Fukushima, [5]University of Tsukuba, Tsukuba, [6]Tokai University, Tokai, [7]Osaka University, Osaka, [8]Kumamoto University, Kumamoto, Japan

Background: Minor populations of glycosylphosphatidylinositol-anchored protein (GPI-AP)-deficient (GPI[-]) cells are often detected in patients with acquired aplastic anemia (AA) or low-risk myelodysplastic syndromes (MDS) and are known to predict a good response to immunosuppressive therapy (IST) and a favorable prognosis. Recently, the Clinical and Laboratory Standards Institute (*CLSI*) established a high-sensitivity flow cytometry (FCM) assay using fluorescence-labeled aerolysin (FLAER)/CD24/CD15/CD45 (CLSI method) that can detect GPI(-) cells at a sensitivity of 0.01%. We have been using a different high-resolution FCM method that defines ≥0.003% GPI(-) granulocytes and ≥0.005% GPI(-) erythrocytes as an abnormal increase. The principle of this method (OPTIMA method) is based on the elimination of as many false GPI(-) cells that can be detected in healthy individuals as possible. However, whether GPI(-) cells detected by the two different FCM assays identify the same GPI(-) cell population is unclear.
Aims: To compare these two high-sensitivity FCM assays, we performed the clinical study "Comparison of Methods in PNH clone size Assessment by CLSI Recognized or Enhanced high-sensitivity flow cytometry (COMPARE)", which aimed to determine the percentage of GPI(-) cells in peripheral blood of BM failure (BMF) patients possessing minor populations (0.003%-0.01%) of GPI(-) cells, and studied the clinical characteristics of these patients.

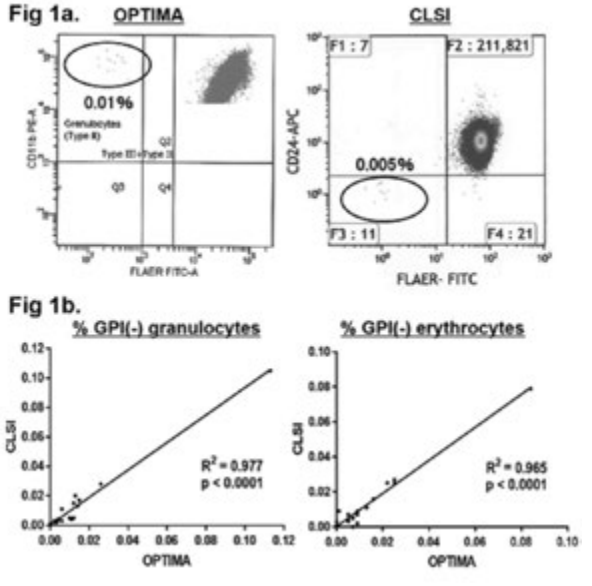

Figure 1.

Methods: We analyzed the peripheral blood of 18 BMF patients (13 AA, 3 MDS, and 2 undifferentiated BMF) who had been judged positive for GPI(-) cells (around 0.01%) by previous analyses using the OPTIMA method. New blood samples were subjected to CLSI and OPTIMA assays on the same day at two different institutions. For 8 of the 18 patients, chronological changes in the GPI(-) clone size were studied over a 3-year period.
Results: GPI(-) granulocytes≥0.003% were detected in 14 patients (78%) by the OPTIMA method, while GPI(-) granulocytes≥0.01% were detected in 7 patients (39%) by the CLSI method. The OPTIMA method revealed 0.003%-0.012% GPI(-) granulocytes in 7 patients who were judged negative by the CLSI method because their GPI(-) granulocyte percentages were less than 0.01% (0.002%-0.005%) (Fig 1a). Four BMF patients who had 0.003%-0.012% GPI(-) granulocytes in previous OPTIMA analyses were judged GPI(-) cells negative by both methods, due to spontaneous regression of their PNH clones. The median GPI(-) granulocyte clone size of the PNH-positive patients was 0.011% (0.003%-0.113%) with the OPTIMA method and 0.017% (0.011%-0.105%) with the CLSI assay. The clone sizes of GPI(-) cells revealed by each assay were positively correlated (Fig. 1b). Of the 14 BMF patients with GPI(-) cells revealed by the OPTIMA, 9 patients (8 AA and 1 MDS-RCMD) received IST (4 with ATG+ CsA and 5 with CsA monotherapy), and all of them achieved partial or complete remission. The GPI(-) clone size of 8 BMF patients (5 AA and 3 MDS) was monitored over a 3-year period, and 0.003%-0.048% GPI(-) clones were consistently revealed by the OPTIMA method in all cases.
Summary/Conclusion: Both high-sensitivity FCM methods produced comparable results in terms of detecting minor GPI(-) cell populations. However, when the CLSI method is used to detect GPI(-) cells in BMF patients, some patients who were actually positive for minor GPI(-) cell populations may be judged negative due to its high cut-off level (0.01%). Thus, caution is needed when<0.01% GPI(-) cells were revealed by the CLSI method; the patients may be positive for increased PNH-type cells and likely to respond to IST.

PB1823

FEASIBILITY AND EFFICACY OF COMBINED TREATMENT WITH ELTROMBOPAG AND DEFERASIROX IN PATIENTS AFFECTED BY APLASTIC ANEMIA

D. Cilloni[1,*], L. Biale[2], D. Capelli[3], C. Frairia[4], S. Galimberti[5], L. Giaccone[6], S. Macchi[7], M. Ruggeri[8], F. Russo[9], M. De Gobbi[1], A. Tendas[10], C. Finelli[11]

[1]Dept of Clinical and Biological Sciences, University of Turin, Orbassano, [2]banca del Sangue, Città della Salute e Della Scienza, Turin, [3]Division of Hematology, University of Ancona, Ancona, [4]Division of Hematology, Città della Salute e Della Scienza, Turin, [5]Division of Hematology, University of Pisa, Pisa, [6]Division of hematology, University of Turin, Turin, [7]Banca del Sangue, Ospedale di Borgomanero, Borgomanero, [8]Division of Hematology, ULSS [8] Berica, Vicenza, [9]Division of Hematology, University of Parma, Parma, [10]Division of Hematology, San Eugenio Hospital, Rome, [11]Dept of Hematology, Seragnoli Institute, University of Bologna, Bologna, Italy

Background: Aplastic anemia (AA) is characterized by immune-mediated bone marrow hypoplasia and pancytopenia, and can be effectively treated with immunosuppressive therapy or allogeneic transplantation. Nevertheless, one third of patients are refractory to immunosuppression, with persistent, severe cytopenia and transfusion requirement. Eltrombopag (ELT) is an orally bioavailable thrombopoietin receptor (TPO-R) agonist approved for the treatment of refractory idiopathic thrombocytopenia and aplastic anemia. Additionally It was shown that ELT is also able to decrease labile iron within the cells. Since in many studies hematological response was reported during iron chelation therapy (ICT) in patients with AA, similarly, in principle, some beneficial effects of ELT on hematopoiesis could also derive from its property to remove iron".
Aims: The study was a retrospective collection of clinical data of patients with AA treated concomitantly with eltrombopag and deferasirox (DFX) with the aim of investigating the tolerability of the association and the response rate of AA patients treated in 11 Italian hematological centers.
Methods: We collected 14 AA, 2 cases of MDS and 1 case of B-CLL. Four patients with AA were excluded because the follow-up was less than 2 months or because the ICT and ELT were not concomitant. The median time of ELT therapy in the 10 AA patients was 15 months. In 8 out of 10 patients DFX therapy was started before ELT. The median time from diagnosis to ELT therapy was 9 months. All the patients were heavily transfused before ELT therapy. The median number of transfusions before ELT therapy was 33.5 U of RBC and 31 U of platelets. The median serum ferritin level was 2600 ng/mL at ELT starting and 1480 ng/mL at the end of ELT and DFX treatment. All the patients gradually reached the dose of 150 mg/d of ELT and were treated with a median dose of 10 mg/kg of DFX.
Results: Seven out of 10 AA patients (70%) obtained complete hematological response with transfusion independence, one a partial erythroid response and one has a significant reduction of platelets transfusion. One patient did not obtain any benefit. The two MDS cases and the B-CLL case obtained transfusion independence. The combination was well tolerated and no unexpected side effects or significant alterations of blood chemistry occurred.
Summary/Conclusion: Although the retrospective nature of our observation and the limited number of patients included, our multicenter experience with the association of ELT and DFX results in a good rate of tolerability

and a surprising rate of responses. If these data will be conformed in a larger cohort of patients, these data will pave the way to prospective trials and biological studies to investigate the eventual role of iron removal in favoring eltrombopag response.

PB1824

DISTINCT DYNAMICS OF PNH CLONE AND HEMOLYTIC MANIFESTATIONS ACCORDING TO BASELINE CLONE SIZE IN PATIENTS WITH APLASTIC ANEMIA/PNH AFTER IMMUNOSUPPRESSIVE TREATMENT: PROSPECTIVE OBSERVATIONAL STUDY

S.-S. Park*, G.J. Min, Y.-W. Jeon, J.-H. Yoon, S.-E. Lee, B.-S. Cho, K.-S. Eom, Y.-J. Kim, S. Lee, H.-J. Kim, C.-K. Min, S.-G. Cho, D.-W. Kim, J.W. Lee

Division of Hematology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Clonal expansion or its clinical impact after immunosuppressive therapy (IST) was not fully elucidated in patients with paroxysmal nocturnal hemoglobinuria (PNH) in the context of aplastic anemia (AA) (AA/PNH).
Aims: This study aimed to identify the dynamics of PNH clone and proportion of hemolytic manifestations according to baseline clone size during the course of AA/PNH after IST.
Methods: A cohort of 63 patients who received IST at the time of diagnosis of AA/PNH was enrolled in this study. Hemolytic AA/PNH was defined as AA/PNH with elevated lactate dehydrogenase (LDH) ≥1.5 times the upper limit of normal (ULN). Data of each PNH clone were collected at diagnosis, 6, 12, 24 months after diagnosis of AA/PNH. PNH clone of granulocyte was measured by high-sensitivity flow cytometry (FC). The sensitivity limit of FC was 0.01% of granulocyte population. We divided patients into two groups according to granulocyte clone size at the time of diagnosis for AA/PNH: group-A (n=17) consisted of patients who showed PNH clone size ≤1%, and group-B (n=46) patients who had PNH clone size >1%.

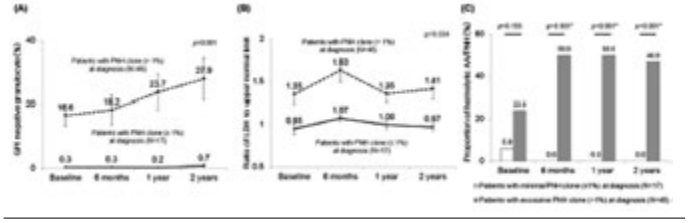

Figure 1.

Results: The median age of patients was 44 years (range, 18-79) and 12 patients (19.0%) had hemolytic AA/PNH at diagnosis of AA/PNH. During median follow-up periods of 36.0 months (5.8-90.6) from diagnosis of AA/PNH, overall response rate (ORR) of IST was 82.5% without significant intergroup difference between group-A and B (88.2% *vs* 80.4%, *p*=0.712). The median clone size and LDH value were 2.5% (range, 0.1-85.7) and 1.07 (range, 0.50-4.36) x ULN, respectively. Twenty-five patients (39.7%) developed hemolytic AA/PNH during the clinical course. Compared to dynamics of group-A, those of group-B showed significant upward trend of clone size over time (p<0.001) (Fig A). After 2-years from diagnosis, average PNH close size of group B was significantly increased from the baseline (16.6% at diagnosis to 27.9% at 2 years, *p*=0.024), whereas that of group A was not changed (0.3% at diagnosis to 0.7% at 2-years, *p*=0.932). There were no significant difference of median LDH value between baseline and 2-year in both groups (0.95x ULN to 0.97x ULN in group A, *p*=0.600, whereas 1.35x ULN to 1.41x ULN in group B, *p*=0.063) (Fig B). However, despite similar frequencies of hemolytic AA/PNH at baseline between group-A and B (5.9% in group-A *vs* 23.9% in group-B, *p*=0.155), the proportions of hemolytic AA/PNH in group-B were significantly higher at 2-year compared to those of group-A (46.9% *vs* 0.0%, *p*<0.001) (Fig C).
Summary/Conclusion: Current study demonstrate that there were significant differences in the dynamics of the PNH clone and its hemolytic manifestations according to 1% of baseline PNH clone size as cut-off in patients with AA/PNH after IST. Although ORR of IST was similar between two groups, it is suggested that the regular monitoring of PNH clone and LDH value in AA/PNH should be performed in patients with clone size >1% at baseline to identify the clonal expansion and hemolytic manifestations earlier after IST.

PB1825

HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN ADULTS-A RETROSPECTIVE ANALYSIS FROM A SINGLE INSTITUTION

B. Batko[1], J. Biernat[1], M. Pukal[1], P. Krawiec[1], M. Machaczka[2,3,*]

[1]Department of Rheumatology, J. Dietl Specialist Hospital, Krakow, [2]Medical Faculty, University of Rzeszow, Rzeszow, Poland, [3]Hematology Center Karolinska, Karolinska University Hospital Huddinge, Stockholm, Sweden

Background: Hemophagocytic lymphohistiocytosis (HLH) is a hyperinflammatory condition caused by highly stimulated but dysregulated and ineffective immune responses. Cardinal features of HLH are fever, hepatosplenomegaly, pancytopenia, and lymphohistiocytic proliferation. HLH is an underdiagnosed but potentially life-threatening clinicopathological syndrome often occurring in adults with hematological malignancies and autoimmune disorders.
Aims: To describe clinical characteristics of adults with reactive HLH/macrophage activation syndrome (MAS).
Methods: From Jan 2009 onwards, data on adults referred to the Rheumatology Department (2000 hospitalized patients per year) of the J. Dietl Specialist Hospital in Krakow (inhabited by approx. 1 million people) with suspected HLH/MAS were collected. The diagnosis of HLH was based on the HLH-2004 guidelines and HScore. In all patients, aspiration biopsy of bone marrow (BM) and/or lymph node was performed to evaluate a presence of hemophagocytosis. Connective tissue diseases were diagnosed according to international criterias. Infection as a possible additional trigger of HLH was carefully studied in all patients. EBV and CMV were routinely examined in whole blood; blood and urine cultures were performed in order to reveal any bacterial infections. The patient's medical records were reviewed to collect relevant clinical data. The patients provided their informed consent. The study was performed according to the ethical guidelines of the Declaration of Helsinki.
Results: Seven adults (4 female, 3 male), aged 20–59 years (median age 31 years), were diagnosed with aggressive HLH during the 8.5-year period between Jan 2009 and Jul 2017. Of these, two patients suffered from adult onset Still disease, one from childhood onset ankylosing spondylitis, one from systemic lupus erythematosus, one from systemic onset juvenile idiopathic arthritis, one from connective tissue disease UNS, and one from Erdheim-Chester disease. All patients presented with unremitting fever, splenomegaly, and hyperferritinemia ≥500 μg/L (median 5731, range 1469-27760). Hemophagocytosis was present in all but one patient, though only in 3 patients on the first examination. A newly developed cytopenia was present in 3/7 patients according to HLH-2004 and in all patients according to HScore. HLH-2004 criterion of hypertriglyceridemia ≥3 mmol/L and/or hypofibrinogenemia ≤1.5 g/L was fulfilled in 5/7 patients. An inflammatory state was observed both from elevated CRP (median 49,4 mg/L, range 14-277) in all patients, and low ESR (median 17 mm, range 8-45) in all but one patient. In 3 patients, the HLH trigger was identified as an active EBV infection (IgG EBNA, VCA), and for one patient HSV was suspected. One patient presented with neuropsychiatric symptoms that were not accompanied at first by any MRI abnormalities, though CSF revealed hemophagocytosis.
Summary/Conclusion: Clinical and biological features of HLH (*e.g.*, fever, splenomegaly, cytopenia, hyperferritinemia) are not specific and can also occur in other disorders. It may be difficult to distinguish HLH from other diseases such as severe sepsis, hematologic malignancies or exacerbation of rheumatic disease. Thus, the HLH/MAS diagnosis may be overlooked or delayed. Timely diagnosis is crucial since early administration of effective treatment (*e.g.*, HLH-94 therapy) may improve survival. The knowledge of HLH-2004 and HScore diagnostic criteria among physicians is essential to increase a recognition of this syndrom.

PB1826

IMMUNOLOGICAL STATUS OF PATIENTS WITH DIAMOND BLACKFAN ANEMIA

F. Gumruk[1,*], G. Soltanova[2], N. Akarsu[1], M. Cetin[1], S. Unal[1]

[1]Center for Fanconi Anemia and Inherited Bone Marrow Failure Syndromes, [2]Department of Pediatrics, Hacettepe University, Ankara, Turkey

Background: Diamond Blackfan anemia (DBA) is a rare genetic disease characterized with anemia, reticulocytopenia, paucity of erythroid precursors in the bone marrow, dysmorphic features and propensity for malignancy.
Aims: DBA is a ribosomopathy that affects mainly erythroid lineage, however as being a ribosomopathy it may have impact in other cell lines. Besides, there is limited data on the immunological status of DBA patients in the reported literature.

Methods: Out of 45 DBA patients, 32 (71%) were evaluated with serum immunoglobulin (Ig)A, IgG and IgM levels and 28 (62%) were evaluated with lymphocyte subset analyses. The values of the patients were compared to age appropriates.
Results: Of the 32 patients analyzed for Ig levels, 14 (43.7%) were found to have low levels of at least one type Ig. Two patients were found to have low IgA (6.2%), three (9.4%) had low IgM, four (12.5%) had low IgG, one (3.1%) had combined low levels of IgA and IgM, one (3.1%) had combined low levels of IgA and IgG, three (9.4%) had low levels of IgA, IgM and IgG at the same time compared to age appropriates. Six (21.4%) out of 28 patients analyzed for lymphocyte subsets were found to have low CD19+ B cells and four (14.3%) had low NK cells. Five of the patients analyzed for immunological status were found to have *CECR1* gene mutation, causing ADA2 enzyme deficiency associated DBA-like phenotype. Of these five ADA2 deficient patients four (80%) were found to have low Ig levels and three (60%) had lymphocye subset abnormalities.
Summary/Conclusion: There is limited data on the immune status of patients with DBA. Our results indicate a high rate of immune function abnormalities in patients with DBA. ADA2 deficiency is autosomal recessively inherited and could be higher in rate in our study compared to other registries, related to higher rates of consanguineous marriages in our country. ADA2 deficiency has been reported to cause subtle immunological defects and mild immunodeficiency symptoms, in addition to DBA. hematological findings. This might also have contributed to higher rate of immune function abnormalities in our registry.

PB1827

ELTROMBOPAG'S ADDITIVE VALUE IN THE THERAPY OF PEDIATRIC ACQUIRED APLASTIC ANEMIA: A SINGLE INSTITUTION EXPERIENCE

M. Filippidou[1,*], G. Avgerinou[1], K. Katsibardi[1], N. Tourkantoni[1], H. Tsipou[1], K. Roka[1], E. Rigatou[1], N. Selenti[2], A. Kattamis[1]

[1]Division of Pediatric Hematology-Oncology, First Department of Pediatrics, [2]Department of Medical Genetics, University of Athens, Aghia Sophia Children's Hospital, Athens, Greece

Background: Acquired Aplastic Anemia(AAA) is a rare bone marrow failure syndrome characterized by peripheral blood pancytopenia and marrow aplasia, probably caused by an immune-mediated destruction of hematopoietic stem and progenitor cells. Treatment includes hematopoietic stem-cell transplantation (HSCT), particularly by a matched sibling donor or immunosuppressive therapy(IST) with anti-thymocyte globulin(ATG) and cyclosporine A(CSA). Eltrombopag(ELT), a small, oral, non-peptide thrombopoietin receptor agonist has been shown to improve trilineage hematopoiesis and was recently approved as front-line treatment for AA in adults.
Aims: We report the therapeutic approach of children with AAA, treated in our Department in the last 5years.
Methods: Sixteen children (10males/6females) of mean age 8.7 (range:2-16years) were diagnosed with severe AAA since 2012. Causative agents or concurrent events included treatment with NSAIDs(1/16), infuenza virus infection(1/16), autoimmune hepatitis(1/16), transaminasemia of unknown etiology(2/16). Diagnosis was established by bone marrow aspirate and biopsy. Other bone marrow failure syndromes, either inherited (Fanconi anemia, Shwachman-Diamond syndrome) or acquired (Paroxysmal Nocturnal Hemoglobinuria) and hypoplastic myelodysplastic syndromes were excluded.
Results: Should a fully-matched sibling donor be available, patient underwent HSCT (3 patients). One patient received autologous cord blood, after standard HSCT preparatory regimen. The remaining 12 patients were treated with standard IST. ELT was added to IST as an off-label treatment, after approval from regulatory authorities in 11 patients. It was initiated on day 0, ≤4 weeks or >4 weeks post IST in 3,6 and 2patients respectively. ELT was given at a starting dose between 25-150mg/d depending on age/weight of the patient and it was further adjusted for platelet count >100,000 and <150,000/mm^3 (max dose 150mg/d). All 4 patients having received HSCT as first line treatment achieved complete remission. Of the patients treated with IST, 1 patient is still under ELT treatment showing progressive improvement of peripheral blood values 4 months post IST, 8 patients are in remission after receiving ELT treatment for a mean time of 10.7 months. Treatment with ELT was well tolerated and there was no evidence of clonal evolution or marrow fibrosis. The remaining 3patients (including the one that did not receive ELT) failed IST, and subsequently underwent MUD-HSCT (3, 4 and 18 months post IST, respectively), with fatal outcome in 2 and severe morbidity in 1 (renal failure).
Summary/Conclusion: Survival in severe AAA has remarkably improved due to early therapeutic interventions (allo-HSCT or immunosuppressive therapy) and improved supportive care. This small series of children with AAA underlines the option of new effective, well-tolerated modalities including autologous cord blood transplantation and adding ELT in IST, and the possible significant mortality/morbidity of MUD when used as a 2nd line therapy. ELT seems to enhance tri-linear recovery in children, in a manner similar to the one observed in adults with AA. Long-term-follow-up remains important to identify possible late complications (clonal evolution, leukemia or autoimmunity).

PB1828

BEST PRACTICE GUIDANCE FOR NURSES MANAGING PATIENTS WITH PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA ACROSS THE LIFE SPECTRUM

L. Arnold[1,*], M. Brown[2]

[1]Haematology, Leeds Teaching Hospitals Trust, Leeds, United Kingdom, [2]Royal Melbourne Hospital, Melbourne, Australia

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired disease characterized by chronic, complement mediated intravascular haemolysis. Nurses play a critical role in the holistic management of PNH. Due to the rarity of the disease, experience and knowledge in managing patients with PNH is lacking for many nurses, and there is currently no literature specific to the nurse care setting published to date.
Aims: To address different issues and aspects of PNH that commonly arise across the different stages of a patient's life, and provide specialised guidance for nurses.
Methods: This is a collaboration of real-world experience and expert opinion by two world-leading PNH nurse specialists, and is supported by evidence based on current literature. Common issues are discussed in relation to different life stages; 1) teenagers and adolescents 12-20 years, 2) early adults 20-40 years, 3) middle age adults 40-60 years, 4) retirees >60 years, and 5) all life stages, with the intent to prompt and raise discussions that are relevant to each patient.
Results: The most commonly identified issues for each life stage discussed are 1) Behavioural and psychological issues, acceptance of their condition, and adherence to prophylactic antibiotics for teenage and adolescent patients. 2) Contraceptive methods, reproductive concerns, and pregnancy planning and management for early adults. 3) Alternative/holistic therapies and age related comorbidities for middle aged adults. 4) Home care services, cannulation and central device issues and when to stop eculizumab/start palliative care for the retiree age group. 5) Managing travel and preserving vein integrity for all age groups.
Summary/Conclusion: Nurses play a vital role in managing patients with PNH across their life course. By identifying potential issues and providing best practice guidance on matters that may arise during a patient's life journey, nurses can be better educated and equipped to provide the best care for their patients.

PB1829

PAROXYSMAL NOCTURNAL HEMOGLOBINURIA IN CHILDHOOD AND ADOLESCENCE- A 5-YEAR RETROSPECTIVE ANALYSIS FROM A SINGLE TERTIARY CARE CENTER FROM NORTH INDIA

R. Halder*, M. Aggarwal, M. Mahapatra, R. Dhawan, T. Seth, S. Tyagi, H.P. Pati, R. Saxena, S. Mirgh, S. Kothari, U. Kumar, R. Chauhan

Department of Hematology, All India Institute of Medical Sciences, New Delhi, India

Background: Paroxysmal nocturnal hemoglobinuria is not well recognized in pediatric age group.
Aims: To Study the clinical profile and laboratory data of children with PNH positive clone.
Methods: We analyzed the hospital records for patients of classical paroxysmal nocturnal hemoglobinuria and aplastic anemia/hypocellular bone marrow patients in the pediatric age group (<18years age) from 2013 to 2017. The clinical and laboratory data of patients with PNH clones were collected from the hospital records. PNH clone was identified by flowcytometry. Patients with classical PNH were treated with a combination of steroids with or without androgens and those with PNH/AA were treated with cyclosporine+/-androgens.

Results:

Table 1.

Symptoms at diagnosis	Classical PNH n=10(%)	PNH/AA n=29(%)
Palloe/Fatigue	10(100.00)	29(100.00)
Jaundice	5(50.00)	2(6.89)
Hemoglobinuria	5(50.00)	3(10.34)
Bleeding (Petechiae/Purpura/wet bleeds)	0	11(37.93)
Seizures	1(10.00)	0
Fever	5(50.00)	14(48.27)
Thrombosis	1(10.00)	0
Dysphagia/Chest pain/Abdominal Pain	2(20.00)	1(3.44)

Table 2.

	Classical PNH	PNH/AA	Total
Median age to presentation, years (range)	16.0 (13.7-16.7)	16.0(14.0-18.0)	16.0(14.0-18.0)
Median age to diagnosis, years (range)	18.0(16.0-19.0)	16.0(14.0-18.0)	16.0(15.0-18.0)
Duration of symptoms, months (range)	30(24-36)	3(2-6)	5(2-12)
Laboratory results			
Hb, g/dL	5.8(4.6-8.2)	5.4(4.5-7.3)	5.8(4.5-7.5)
WBC x 10⁹/L	4.1(3.2-5.6)	3.1(2.5-3.6)	3.2(2.6-3.7)
ANC x 10⁹/L	1.6(0.8-3.0)	0.5(0.3-0.7)	0.6(0.4-1.1)
Platelet x 10⁹/L	74.0(52.0-150.0)	20.0(10.0-40.0)	30.0(15.0-59.5)
Reticulocyte x 10⁹/L	57.0(50.0-67.0)	1.0(0.06-2.0)	20.0(0.9-40.0)
Total Bilirubin, mg/dl	1.4(0.8-2.0)	0.7(0.5-0.8)	0.8(0.5-1.1)
PNH clone size			
Granulocyte clone size, %, median (range)	79.0(40.6-86.0)	3.0(1.0-8.0)	5.2(2.0-28.2)
Monocyte clone size, %, median (range)	91.5(86.3-97.5)	6.0(3.2-14.4)	10.8(3.8-64.6)

14 patients were in CR, 11 patients were in PR and rest did not have any response. Only one patient was able to undergo allogenic stem cell transplantation.

Summary/Conclusion: There is significant delay in the diagnosis of the classic form of PNH in children and more awareness is to be created regarding this disorder in children. Thrombotic events were also less common in our patient population.

PB1830

CHROMOSOME FRAGILE SITE 16B AND BENIGN NEUTROPENIA: A FAMILIAR CASE STUDY

N. S. Fracchiolla[1,*], V. Ferla[1], E. Fermo[1], D. Morotti[2], W. Barcellini[1], A. Cortelezzi[1]

[1]Hematology Unit, [2]Cytogenetics Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy

Background: Neutropenia is defined as an absolute neutrophil count (ANC)<1500 cells/mmc, can be acquired or inherited (autosomal dominant). The latter is rare and may be mild or severe, some forms may be associated with a malignant transformation in Acute Myeloid Leukemia and Myelodisplastic Syndrome. A fragile site on chromosome 16 associated to severe familiar neutropenia with variable clinical severity has been described in two cases, one of which with recurrent infections.
Aims: We have identified an additional case of a familial benign chronic neutropenia with karyotype abnormalities represented by deletion and fragile site (FRA16B) on chromosome 16 at band q22.
Methods: Chromosome studies: for evidencing FRA16B, 16q22.1, DAPI colture was used. Molecular studies: Array comparative genomic hybridization (a-CGH) was performed using Agilent SurePrint G3 Human 4x180K kit. Molecular analysis of ELANE gene (19p13.3) was performed
Results: A 35 years old Caucasian female presented with neutropenia known since the age of 15 years old with average values of neutrophils of 500/mmc. Bone marrow (BM) was normal 25 yrs before. No history of recurrent infections was reported. Hepatosplenomegaly or lymphadenopathy were absent. Blood analysis showed hemoglobin 12 g/dl, white blood cells 2000/mmc, neutrophils 640/mmc, lymphocytes 1190/mmc, monocytes 120/mmc and platelets 334.000/mmc. Screening tests for autoimmunity and anti-neutrophil antibodies (direct and indirect granulocyte immunofluorescence test; GIFT method), antiphospholipid antibodies, HIV, HCV and HBV were negative. Coagulation tests were normal. BM aspirate and biopsy resulted normal. At the age of 37 and 38 years old, the patient experienced severe pneumonia responding to antibiotic intravenous therapy with normal neutrophils and increased inflammatory markers. Karyotype on bone marrow sample evidenced the presence of a del(16)(q22) in 12 out of 20 examined metaphases. Unstimulated peripheral blood karyotype evidenced the presence of a cells population (~ 35%) with the same fragile site FRA16B (16q22.1). ArrayCGH analysis of patient was normal. No mutations in ELANE gene were detected. Due the heritability of fragile site a constitutional study of her family was performed. The patient's mother, 74 years old, had a severe neutropenia with neutrophils 500/mmc, without recurrent infections. Cytogenetic analysis on peripheral blood uncultured and coltured with fragile site inducting factors showed fra(16)(q22). The 52 years old brother had a mild neutropenia with neutrophils 1500/mmc. And the fra(16) was detected in PB only after culture with fragile site inducting factors. The patient's father and sister showed normal blood count, with a normal karyotype
Summary/Conclusion: We describe a family that presents the simultaneous occurrence of FRA16B (16q22.1) and neutropenia in three of its members (the patient, the mother and one of two siblings). In this family, the presence of FRA16B (16q22.1) correlated specifically with neutropenia, that, interestingly, was deeper in those members (the patient and the mother) in which the fragile site was evident without the need of fragile site inducing factors culture. Even it is not possible to substantiate a causative role of FRA16B (16q22.1) in familiar neutropenia, the family described here prompts further studies to explore the possibility that this association may represent a subset of familiar neutropenias with specific, albeit not yet unraveled, genetic lesions.

PB1831

ELTROMBOPAG FOR THE TREATMENT OF APLASTIC ANEMIA-CROATIAN EXPERIENCE

D. Pulanic[1,*], A. Boban[1], M. Vodanovic[1], I. Krecak[2], V. Blaslov[3], V. Gveric-Krecak[2], M. Jakic-Bubalo[3], S. Zupancic Salek[1]

[1]Department of Internal Medicine, Division of Hematology, University Hospital Center Zagreb and Medical School University of Zagreb, Zagreb, [2]Department of Internal Medicine, General Hospital of Sibenik-Knin County, Sibenik, [3]Department of Internal Medicine, Division of Hematology, University Hospital Center Split, Split, Croatia

Background: Eltrombopag, a peroral thrombopoietin receptor agonist, has been introduced recently as a possible novel therapeutic option for adult patients with acquired severe aplastic anemia (SAA) who were either refractory to prior immunosuppressive therapy or heavily pretreated and were unsuitable for hematopoietic stem cell transplantation (HSCT). However, it is still not known how eltrombopag is used for that indication in the real-world setting.
Aims: In this work we analyzed results of eltrombopag usage in Croatia for the treatment of patients with SAA or very severe aplastic anemia (vSAA) outside of clinical trials.
Methods: We conducted a retrospective analysis on the use of eltrombopag for SAA or vSAA patients among Croatian hematology centers.
Results: From March 2015 until February 2018 seven adult patients (4 (57%) female, median age 63 (38-79) years) with acquired aplastic anemia were treated with eltrombopag in Croatian hematology centers: 3 among them with SAA, 3 with vSAA, and 1 with PNH with SAA fenotype. All patients received eltrombopag after at least one previous line of immunosuppressive treatment, either as a monotherapy (2/7) or in combination with CyA +/- low dose methylprednisolone. Complete remission (CR) (defined as Plt >100/mcL and Hb >100 g/L and Neutrophils >1.5/mcL) achieved 2 patients, partial remission (PR) (defined as transfusion independence) 1 patient, minimal response (defined as some improvement in 1 or more lineage but not fulfilling the criteria of PR) 1 patient, and 3 patients were refractory to eltrombopag. Median time of eltrombopag administration was 5 (3-25) months. Median eltrombopag dose was 150 mg per day and adverse events were consistent with the known safety data of the drug. Two patients in CR are receiving eltrombopag for 25 and 14 months, respectively. One patient who achieved minimal response relapsed after 8 months of treatment and developed new cytogenetic change (trisomy 8). 85.7% of patients are alive at a median follow up of 12 (5-32) months. Only one patient died, 8 months after discontinuation of eltrombopag therapy, with refractory vSAA, comorbidities and infections.
Summary/Conclusion: Presented data from Croatian hematology centers in the real-world setting confirm that eltrombopag is interesting new modality to treat patients with acquired SAA, especially for those who are refractory to prior immunosuppressive therapy and/or unsuitable for HSCT.

PB1832

PIGA MUTATIONS AS A PREDICTORS OF TREATMENT RESPONSE IN PNH

H.S. Park[1,*], S. Choi[1], H. Seo[2], S.-M. Kim[3], K. Im[4], J. Yun[1], D. Jeong[1], J.-A. Kim[5], S.M. Hwang[6], K. Kim[7], J.H. Kim[2], D.S. Lee[1]

[1]Department of Laboratory Medicine, [2]Division of Biomedical Informatics, [3]Cancer Research Institute, [4]Institute of Reproductive Medicine and Population Medical Research Center, Seoul National University, [5]Department of Laboratory Medicine,

Chung-Ang University Hospital, Seoul, [6]Department of Laboratory Medicine, Seoul National University Bundang Hospital, Seongnam, [7]Division of Clinical Bioinformatics Research Institute, Seoul National University Hospital, Seoul, Korea, Republic Of

Background: The detection of extremely small clone (<0.01%) became possible through high-sensitive flow cytometry (FCM), but the clinical significance of small PNH clone has not been elucidated.
Aims: To investigate a correlation of *PIGA* mutation and small PNH FCM clone, we measured PNH FCM clone size and mutant burden of *PIG* gene, with their correlation to treatment response.
Methods: A total of 89 specimens from 63 patients whose PNH clone size was ≥0.1% by FCM was enrolled (classic PNH 9, PNH related with bone marrow disorder 47, subclinical PNH 10). To detect minor cell population with *PIG* mutation, we adopted ultra-deep sequencing for *PIGA*, *PIGM*, *PIGX and PIGT* mutation.
Results: Twenty two% of 63 patients with PNH FCM clone harbored *PIG* gene mutation and 92.8% of patients with *PIG* mutation had >10% PNH FCM clone in RBC and granulocyte. In classic PNH patients (n=6), the average of PNH FCM clone size was 56.8% in RBC and 89.6% in granulocyte, and all patients had *PIG* gene mutation. In patients with subclinical PNH clone, the average of PNH FCM clone was 1.8% in RBC and 3.3% in granulocyte, while *PIG* gene mutation was not detected. In the patients with coexisting bone marrow disorder (BMD), the average of PNH FCM clone size was 8.0% in RBC and 14.9% in granulocyte. Among 6 patients with Eculizumab treatment, hemoglobin increment and decrease of FCM RBC clone size correlated, while LDH decreased in all patients, irrespective of treatment response. Decrease of the ratio over 0.15 (type III/type II+III PNH clone in RBC) was a predictive factor for complete response at 6 months from treatment initiation. Of the 11 patients with consecutive results of *PIG* mutation, 88% of patients with *PIG* mutations was non-responsive to supportive treatment, while 33% of patients without *PIG* mutations was non-response (p=0.072). Mutant burden of *PIG* gene mutation were not changed during treatment irrespective of types of treatment.
Summary/Conclusion: The *PIG* gene mutation was detected only in patients with >10% FCM PNH clone and The mutation burden of *PIG* gene was related to the granulocyte FCM PNH clone size. The presence of *PIG* gene mutations was correlated with adverse treatment response. We suggest monitoring of PNH clone in RBC can be a potential predictor of treatment response as well as Hb during treatment with Eculizumab.

PB1833

CLINICOHEMATOLOGICAL AND CYTOGENETIC PROFILE OF APLASTIC ANEMIA IN PAKISTAN

N. Anwar[1,*], A. Arshad[1], Z. Sharif[1], S. Sharif[2], N. Fatima[2], T. Shamsi[1]

[1]Hematology, [2]Research and development, National Institute of blood diseases and bone marrow transplant karachi Pakistan, Karachi, Pakistan

Background: Aplastic anemia are acquired or congenital anemias associated with hypocellular bone marrow. The exact etiology is unknown but several factors are considered to be causative for suppression of hematopoitic cell production resulting in aplastic anemia.
Aims: This entity considered to be uncommon is frequently prevalent with rising trend seen especially in Pakistan. This is quite contrast to what is observed in west. Moreover, there is scarce local data. Hence the study was done to assess baseline clinical and cytogenetics features of patients presenting with aplastic anemia.
Methods: This study was approved by the Institutional Ethics Committee of National Institute of Blood Diseases and Bone Marrow Transplantation. In this cross sectional study,122 patients with aplastic anemia were enrolled during the period of June 2016 to January 2018. Informed consent was obtained prior to the study. Data collected included demographic information, laboratory information, includinggender, symptoms, treatments, blood counts and chemistry parameters including urea, creatinine and liver function tests.Viral profile included Anti-HCV, Anti-HBsAg, HIV I/II and Cytomegalovirus (CMV) performed. Cytogenetic analysis was performed on bone marrow samples and karyotypes were described according to the International System for Human Cytogenetic Nomenclature (ISCN) 2013, karyogram were made using Meta system. Variables were evaluated using SPSS version 23.
Results: A total of 122 patients were included in the study. The median age of the patients was 14±12.59. A slight predominance of males were observed which were (n=76, 62%). Fever and weakness were the most complain found in (n=56, 46%) followed by colitis (n=24, 20%), gum bleeding (n=20, 16%) bruises (n=12, 10%) and shortness of breath in (n=10, 8%) patients. All patients were grouped according to camitta classification. Non severe aplastic anemia were observed in (n=100, 82%) followed by very severe aplastic anemia (n=12, 10%) and severe aplastic anemia (n=10, 8%). The mean hemoglobin was 7.61±2.11g/dl, red blood cells 3.17±3.4x10^{12}/l, MCV 89.2±11.56fl, total leucocytes counts (tlc) 3.09±2.03x10^{9}/l, absolute neutrophils count 0.7±0.99×10^{9}/l and platelets counts were 27±52.29x10^{9}/l. The mean total bilirubin was 0.76±0.38mg/dl, direct bilirubin 0.37±0.27mg/dl, alanine aminotransferase (SGPT) 61±89.5u/l and alkaline phosphatase was 201±116.5u/l. Out of 122 patients, chromosomal breakage was observed in (n=10, 8%) patients. Anti HbsAg was positive in (n=04, 3%) and anti HCV in (n=02, 1.6%).CMV was positive in (n=02, 1.6%) patients.
Summary/Conclusion: In our study we have observed lower median age andmale predominance.Non severe aplastic anemia was most common. Raised SGPT was seen in many indicating liver damage. To overcome adverse prognostic implications, early identification of such patients with close clinical follow up and upfront stem cell transplant must be considered. This study was done retrospectively yet represents a large cohort of aplastic anemia in the country. In future, prospective studies are needed to be done to elaborate disease biology and clinical outcome of the baseline adverse disease characteristics observed in our study.

PB1834

ADA 2 ENZYME DEFICIENCY MANIFESTING AS PURE RED CELL APLASIA

G. Ersoy[1], C. Bayram[1], M. Gökçe[1], S. Ünal[2], N.N. Ozdemir[1,*]

[1]Pediatric Hematology Oncology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, [2]Pediatric Hematology Oncology, Hacettepe University, Ankara, Turkey

Background: Pure red cell anemia is characterized by normochrome normocytic anemia with severe reticulocytopenia and marked decrease or absence in red cell lineage in bone marrow. We herein present a child with congenital pure red cell anemia diagnosed as ADA2 enzyme deficiency to emphasize this rare etiology of pure red cell anemia.
Aims: A 40 day old boy was admitted to our hospital with pallor. On physical examination, there was no hepatosplenomegaly or any stigmates. His laboratory work up showed severe anemia, hgb:2 gr/dl; htc:%5.8; wbc: 9750/mm^3; neu: 1800/mm^3; plt: 690 000/mm^3; MCV:89 fL; LDH:360 U/L. Electrolytes, kidney function tests, and liver function tests were normal. Direct coombs test was negative, reticulocyte count was low (0.2%). On blood smear, erythrocytes were normal in shape and size with no signs of hemolysis. On follow up he was transfusion dependant monthly. Bone marrow aspiration showed decreased erythrocyte progenitor cells. HbF was 5.8%. Viral serology including Parvovirus was negative. Vitamin B12 and folate levels were normal, erythropoetin was 39.9 mU/ml (increased). The diagnosis of pure red cell aplasia was established. He also had a history of recurrent infections and his immunoglobulins were low. The genetic analysis for DBA was negative.
Methods: Whole exome sequencing, showed CECR1 mutation causing ADA-2 enzyme deficiency. His parents were silent carriers. The patient's follow up continues in our outpatient clinic, he receives erythrocte tranfusion and intravenous human immunglobulin monthly.
Results: CECR1 gene is responsible for the synthesis of ADA 2 enzyme which is the major extracellular adenosine deaminase and functions as a growth factor. It was first identified in 2014 in patients with poliarteritis nodosa by exome sequencing and is responsible for a spectrum of autoinflammatory symptoms from vasculitis to thromboembolic events. ADA- 2 enzyme deficiency has been described in around 100 patients until now. Most of the patients had inflammatory symptoms like vasculopathy, lacunar strokes, hepatosplenomegaly or livedo reticularis. Hematologic manifestations were poorly described and unexpected without the inflammatory symptoms or immunodeficiency. In 2016, 5 patients from Israel were reported with hematological manifestations, 2 siblings had congenital pure red cell anemia without any vasculopathy.
Summary/Conclusion: Together with other case reports, our patient represents a new phenotype of this mutation and causes the need for evaluating the functions of ADA 2 in bone marrow.

PB1835

BREAKTHROUGH HEMOLYSIS AND THROMBOEMBOLISM CONTROLLED BY ECULIZUMAB DURING PREGNANCY IN PAROXYSMAL NOCTURAL HEMOGLOBINURIA (PNH): A SINGLE INSTITUTION EXPERIENCE

C. Frairia[1,*], S. Aydin[1], E. Audisio[1], S. D'Ardia[1], G. Iovino[1], B. Nicolino[1],

C. Macchi[2], F. Zizzo[2], F.M. Comoglio[2], T. Todros[2], U. Vitolo[1]

[1]Hematology, AOU Città della Salute e della Scienza di Torino, [2]Obstetric and Gynecology, Department of Surgery, University of Turin, Turin, Italy

Background: Paroxysmal nocturnal hemoglobinuria (PNH) is a rare acquired clonal stem cell disorder characterized by intravascular hemolysis, cytopenia and thrombophilia. Thromboembolism, infection and premature birth are main reasons for significantly increased maternal and fetal morbidity and mortality during pregnancy and the following post-partum period in PNH patients. Therefore, PNH has been considered a relative contraindication for pregnancy. The terminal complement cascade inhibitor Eculizumab prevents fatal complications and nearly normalizes overall survival in PNH. Consequently, it has become the standard treatment in patients with symptomatic PNH. However, there are limited published data regarding the use of Eculizumab during pregnancy, the postpartum period or, more less, during lactation.
Aims: To evaluate the management of pregnancy in PNH in our institution.
Methods: We report three cases of pregnancy in PNH.
Results: A 28 year old PNH patient became pregnant while on Eculizumab and the therapy was continued throughout the whole pregnancy. At diagnosis of her pregnancy (6th week of gestation) anticoagulation therapy with low molecular weight heparin was initiated and continued although no clinical sign of thrombosis was present. She was immediately introduced in an interdisciplinary team for high risk pregnancies consisting of specialists for gynecology, internal medicine, anesthesia and hematology. During the third trimester she developed a breakthrough hemolysis in terms of symptomatic anemia requiring repeated blood transfusions. Hemolysis was successfully controlled by dose escalation of Eculizumab first from 900mg to 1200mg biweekly and consequently shortening the administration interval from a biweekly to a weekly scheme until the birth of the baby. She successfully delivered a healthy baby at term by natural birth without complications. One month after delivery the patient has returned to her usual therapeutic Eculizumab regimen (900mg biweekly). She breastfeed her baby for six months without complications. The anticoagulation treatment was continued, as recommended, for the first three months. The baby girl is developing well according to her age and she is now one years old. Currently, we are managing other two young pregnant PNH patients. Our second patients is a 27 years old girl who became pregnant while she was not on Eculizumab but only in follow up due to indolent disease without hemolysis. She was started with anticoagulation prophylaxis with low molecular weight heparin as soon as the pregnancy was noted, and she started the standard therapeutic Eculizumab regimen (900mg biweekly) from the beginning of second trimester. She is now at the end of the third trimester, fetal growth is regular, no signs of hemolysis on the mother and no thromboembolic complications were noted. The estimated date of delivery is scheduled for the end of March, 2018. The third pregnancy is on a 27 years old PNH patient currently at the 15th week of gestation; she was on Eculizumab standard regimen treatment from 2009 due to breakthrough hemolysis and we are managing her pregnancy according to the policies followed for the first described case.
Summary/Conclusion: Our single center experience reports a favorable outcome of a PNH patient who became pregnant while under Eculizumab, supporting the scarce published experience that this drug can be given safely and can even be escalated during pregnancy in PNH patients, with a good disease control. We are currently managing other two pregnant PNH patients, at the moment without complications.

PB1836

A CASE OF SEVERE CONGENITAL NEUTROPENIA CARRYING A NOVEL HOMOZYGOUS MUTATION IN CSF3R GENE

H. Tokgoz[1], U. Caliskan[1,*], F. Ozkınay[2], H. Onay[2]

[1]Pediatric Hematology and Oncology, Necmettin Erbakan University Meram Medical Faculty, Konya, [2]Medical Genetics, Ege University Medical Faculty, İzmir, Turkey

Background: Severe congenital neutropenia (SCN) is characterized by profound neutropenia and a predisposition to life-threatining bacterial infections. Autosomal dominant, autosomal recessive, X-linked and sporadic SCN forms have all been described. Mutations in several genes including ELANE, GFI1, HAX-1, G6PC3 and WAS are responsible for SCN. CSF3R mutations are extremely rare and usually somatic.
Aims: Here we describe an SCN case having a novel homozygous CSF3R mutation.
Methods: A-5-month-old boy was referred to our department because of neutropenia. There was a history of hospitalization because of cervical lymphadenitis and neck abscess at the age of 3 months. The parents were consanguineous. Physical examination was normal (no dysmorphic findings such as leukoplaki, nail dystrophy, brown ridging on the neck, thumb abnormalities, etc.were present). Laboratory tests revealed a severe neutropenia (300/mm^3). Lymphocyte count, serum immunoglobulin levels and peripheral lymhocyte subset analysis were all normal. Viral infection markers were negative. Neutropenia persistedat the level of 200-400/mm^3. In the following8 weekperiod, the neutrophile count was monitored twice weekly. All neutrophile counts were below 500/mm^3. A bone marrow examination revealed normocellularity and maturation arrest of granulocytic series at the level of band form. Cytogenetic studies were normal. The patient did not respond to G-CSF therapy and the neutropenia persisted. The patient is now 21-month-old and has experienced several febrile neutropenia episodes. Bone marrow transplantation has been planned. Unfortunately to date no HLA matched donor within the family has been found.
Results: Molecular genetic analysis for ELA-2, HAX-1, G6PC3, SBDS were normal. However, in the CSF3R genea novel homozygous p.V224D (c.671 (T>A)) mutation was detected. Using in silico analysis this novel mutation was found to be pathogenic. A functional analysis has been planned.
Summary/Conclusion: CSF3R mutations in SCN cases are usually somatic or *de novo* and inherited form is extremely rare (Triot A, *et al.* 2014). It has been considered that the SCN case described here will expand the mutation spectrum of GCSF3R gene and help to make phenotype-genotype correlations.

Rerefence

BONE MARROW FINDINGS IN COLLAGEN VASCULAR DISEASES ASSOCIATED WITH CYTOPENIAS

D. Elshamy*

Hematology Department, Menoufia Faculty of Medicine, Shebin Elkom, Egypt

Background: the collagen vascular diseases area diverse group of inflammatory systemic disorders thought to be immunologically mediatedincluding systemic lupus erythematosus (SLE), scleroderma, polymyositis and polyarteritisnodosa, they are frequently included in the differential diagnosis for unexplained cytopenias and often prompt a bone marrow evaluation in this population is important.
Aims: to study morphologic and immunohistochemical characteristics of bone marrow involvement in patients with collagen vascular diseases associated with cytopenias
Methods: In the current study, we examined 100 patients. The diagnosis of collagen vascular diseases was made according to diagnostic criteria for each as SLICC for SLE.All patients were subjected to thorough history taking, physical examination, and many investigations were done for them including serology (ANA, Anti dsDNA, AntiCCP, RF), and bone marrow examination was done for all patients.
Results: collagen vascular diseases show female predominance regarding SLE and RA with male: female ratio equal 3:14 and 1:4 respectively. Nephritis and arthritis were the most common presentation in SLE and RA respectively and almost present in all patients followed by hematological manifestations as fatigue and ecchymosis. Normocellular bone marrow was the commonest finding in studied patients followed by hypercellular marrow then hypocellular marrow while dysplastic changes affected erythroid element mostly followed by myloid and megakaryocytic elements regarding eosinipgilic, plasma cells and lymphocytic infiltrations; none of them shows statistically significance
Summary/Conclusion: There were no significant statistical differences between CVDs patients as regard bone marrow findingalso there were no specific bone marrow finding detected in SLE and RA patients.

PB1838

A RARE CAUSE OF ANEMIA: GHOSAL TYPE HEMATO-DIAPHYSEAL DYSPLASIA

K. Yılmaz[1], B. Koc[2,*], G. Dikme[2], H. Kızılocak[2], S. Kurugoglu[3], T. Celkan[2]

[1]Pediatric, Istanbul University, [2]Pediatric Hematology and Oncology, [3]Radyology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Ghosal type hemato-diaphyseal dysplasia (GHDD) is a rare, autosomal recessive disorder characterized by increased bone density with both diaphyseal and metaphyseal involvement and bone marrow dysfunction marked by a corticosteroid responsive, myelopthisic anemia. The gene

responsible for this disease was *TBXAS1* which encodes the thromboxane synthase (TXAS) enzyme.
Aims: We aimed to emphasize the importance of rare genetic disordes in differential diagnosis of anemia.
Methods: Here is reported such a rare case of Ghosal type hemato-diaphyseal dysplasia.
Results: Three year-old-boy was admitted with history of pallor, progressive weakness, pain at lower extremities and abdominal distension for last few months. He was suffering from progressive pallor for the last three months requiring multiple blood transfusions without any bleeding diathesis. His birth, development, immunization, dietary histories were normal. There was history of consanguinity. He had height of 98 cm (25-50th percentile of NCHS), weight of 16 Kg (50-75th percentile of NCHS) head circumference of 50 cm (25-50th percentile of NCHS). Physical examination revealed hepatosplenomegaly and generalize lymphadenopathy (<1cm). Laboratory investigation revealed hemoglobin 6.7 g/dL, MCV: 82.7fl, wbc: 6800/mm^3, plt: 134.000/mm^3, neut: 1600/mm^3 and reticulocyte count 2%. Peripheral smear was hypochromic normocytic with normoblasts. Serum electrolytes, calcium and renal function were within normal limit. Multiple bone marrow aspirations were dry tap. However, bone marrow biopsy revealed myelofibrosis. After biopsy, steroid treatment was initiated and never required blood transfusion. Ultrasonography of abdomen revealed hepatosplenomegaly. Chest X-ray was within normal limit. X-rays of long bones and skull base showed thickening of diaphysis and moderately thickening of skull base. Distal part of femur revealed Erlen-Mayer deformity. The case had myelofibrosis, bone deformities and steroid responsive anemia showing both hematologic and diaphyseal dysplasia of Ghosal hemato-diaphyseal dysplasia. The genetic counseling of the case revealed TBXAS1 homozygous mutation.
Summary/Conclusion: Our report illustrates the need to consider GHDD in children with anemia, myelofibrosis, bony abnormalities, and consanguineous parents. Moreover, this case demonstrates the efficacy of chronic, low-dose steroid therapy.

PB1839

CHRONIC PRIMARY NEUTROPENIA IN ADULTS. A MONOCENTRIC UNIVERSITY HOSPITAL COHORT STUDY

L. Njue*, N. Bonadies, A. Rovo

Hematology, University hospital Bern, Bern, Switzerland

Background: Chronic primary neutropenia (CPN) is a rare benign entity with increased susceptibility to bacterial infections. So far there is no epidemiological data from Swiss CPN patients available.
Aims: We aimed to evaluate patients characteristics, rate of infections and long-term outcomes of adult CPN patients at our policlinic.
Methods: This is a retrospective study, in which we reviewed all patients recorded as chronic neutropenia in our policlinic. Patients with neutropenia secondary to infection, drugs, tumor, malnutrition, vitamin B12 deficiency, benign ethnic neutropenia, T-cell large granular leukemia or associated to pancytopenia were excluded. Repetitive infections were defined as ≥3 episodes per year. Infections requiring hospitalization were defined as severe.
Results: From 1998 to February 2017, we identified 20 adults with CPN. CPN patients were more often female 16/20 (80%). The median age at diagnosis was 27 (range 1-66) years. Five patients were<18 years at diagnosis. The median absolute neutrophil count (ANC) at diagnosis was 0.41 G/L (range 0.0-0.90), and the median ANC at last follow-up was 0.8 G/L (range 0.03-7.36). All patients underwent bone marrow evaluation and there was no clear bone marrow pathology pattern. Two of twelve (16%) patients evaluated for anti-granulocyte autoantibodies were positive. Regarding management, therapy was aimed to provide a normal lifestyle. Thus 12/20 patients (60%) received G-CSF either sporadically (6/12) or continuously (6/12) and all responded with increase in the number of neutrophils. Repetitive infections were recorded in 7/20 (35%) patients. 5 patients (25%) presented a total of 23 severe bacterial infections; of these, 3 were diagnosed during childhood. 13 patients (65%) neither had repetitive nor severe infections, 6 of them were treated with different G-CSF modalities. Three infection episodes occurred in 3 patients who were under treatment with G-CSF and had normal neutrophil count. 19 pregnancies were documented (12 before initial diagnosis), 1 patient received G-CSF during 2 of her 6 pregnancies with good outcome and one patient had an uneventful pregnancy without G-CSF. The median follow-up of this cohort was 122 months. 3 patients were lost to follow-up. No death due to bacterial infections or hematologic malignancies occurred. One patient died due to glioblastoma multiforme 10 years after diagnosis of CPN.
Summary/Conclusion: Our adult CPN patient cohort is characterized by a female predominance and a benign outcome. Patients diagnosed during childhood seem to have a higher risk of infections. No secondary hematological malignancies were observed. G-CSF therapy was based on individual schedules and was well tolerated. The reasons why some patients are susceptible to repetitive infections and others are not, remain to be elucidated.

CLINICAL OUTCOMES IN ADULT PATIENTS WITH APLASTIC ANEMIA: A SINGLE INSTITUTION EXPERIENCE

Y. Petrov[1,*], G. Arnaudov[1], P. Ganeva[1], Z. Popova[2], V. Stoeva[2], S. Mishkarova[2], S. Lozenov[2], M. Donchev[2], G. Balatzenko[3], M. Jagurinoski[4], M. Guenova[4], B. Spassov[2]

[1]Stem cell transplantation, [2]Clinical Hematology, [3]Laboratory of Cytogenetics and Molecular biology, [4]Laboratory of Hematopathology & Immunology, National Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: Severe aplastic anemia (SAA) is a life-threatening disorder characterized by pancytopenia in the peripheral blood and hypocellular marrow. Although both allogeneic hematopoietic stem cell transplantation (HSCT) and immunosuppressive treatment (IST) are available treatments, allogeneic HSCT from a HLA-matched familial donor is preferred by SAA patients. However, approximately two-thirds of patients do not have a suitable HLA-matched sibling donor; therefore, either IST or alternative donor HSCT is employed in such cases. However, previous reports have shown that IST is related with a substantial risk of relapse and clonal evolution. Furthermore, IST often leads to the amelioration of cytopenia rather than cures. Advances in HSCT, such as modification of the conditioning regimen, a better selection of donors by high degree HLA allele level matching and the introduction of low-dose TBI, have improved the outcomes of HSCT in patients with SAA.
Aims: The aim of our study was to compare the outcomes of immunosuppressive treatment (IST) and hematopoietic stem cell transplantation (HSCT) as frontline therapy in young adults with severe aplastic anemia (SAA).
Methods: We retrospectively reviewed the medical records of 24 patients with acquired severe aplastic anemia (SAA). Eleven patients received immunosuppressive treatment (IST) and 13 patients received hematopoetic stem cell transplantation (HSCT) from matched related or unrelated, or alternative donor as a frontline therapy. SAA was defined according to the standard criteria; if patients met these criteria and had a neutrophil count<0.2×109/L, their disease was considered to be very severe aplastic anemia. To assess the effect of treatment modalities on the outcomes, the probable overall survival (OS), failure-free survival (FFS) or event-free survival (EFS) rates were estimated. Complete response was defined as a normal hemoglobin level for age, neutrophil count >1.5×109/L and platelet count >150×109/L. Partial response was defined as transfusion independent and no longer meets the criteria for severe disease. Treatment failure or an event after HSCT was defined as death, primary graft failure, late rejection, relapse and secondary malignancy, whichever occurred first.
Results: Sex, age and the disease status at treatment were comparable between the 2 groups; however, the median time from diagnosis to treatment was longer in the frontline HSCT group than in the frontline IST group (10.1 months *vs* 4.0 months respectively, P=0.025). The overall response rate of IST was 42.1%. Among the 13 patients who underwent frontline HSCT, 11 experienced FFS. Although the 5-year OS was comparable between the frontline HSCT and frontline IST groups (91.3% *vs* 71.2% respectively, P=0.187), the 5-year FFS was significantly higher in the former than the latter (91.3% *vs* 30.7% respectively, P<0.001).
Summary/Conclusion: Both IST and alternative donor HSCT have improved the survival rate of patients with SAA. Our data suggests that frontline HSCT may be a better treatment option than IST for young adults especially in situations where ATG is not available.

PB1841

AN UNUSUAL CASE OF PURE RED CELL APLASIA

M.L. Tung*

Haematology-Oncology, National University Cancer Institute, National University Health System, Singapore, Singapore, Singapore

Background: Acquired pure red cell aplasia (PRCA) is a rare condition and is known to be associated with thymomas. Other associations have been described such as drugs, autoimmune conditions, malignancies and ABO incompatible stem cell transplants.
Aims: Here, we describe an unusual case of PRCA which was associated with both a thymoma and parvovirus infection. As part of the work-up for her thymoma, she was also found to have hypogammaglobulinaemia (Good's syndrome) and positive anti-acetylcholine receptor antibodies without clinical evidence of myasthenia gravis.

Methods: A 45-year-old lady presented with symptomatic anaemia to the haematology clinic. She had no past medical history of note prior to this consultation. She presented with symptoms of a viral illness at another hospital a few weeks prior and was found to have anaemia requiring transfusion. On examination, she was well with mild pallor. The rest of her physical examination was unremarkable with no lymphadenopathy or hepatosplenomegaly. Her heart rate was 87 beats per minute (bpm), blood pressure was 100/53mmHg and her oxygen saturation was 100% on room air. Initial investigations revealed a normochromic, normocytic anaemia with a haemoglobin level of 8.3g/dL. Her white blood cell count (WBC) was $4.2x10^9$/L and absolute neutrophil count (ANC) of $2.25x10^9$/L. Her platelet count was normal. There was also reticulocytopenia with an absolute reticulocyte count of $5.80x10^9$/L. The peripheral blood film showed a normochromic, normocytic anaemia with no other abnormalities seen. A bone marrow examination was performed and revealed an absence of erythropoiesis with preserved granulopoetic and megakaryopoietic activity. Parvovirus PCR was positive as well from the bone marrow sample. A chest computed tomography (CT) demonstrated an anterior mediastinal mass (Figure 1). Given the CT findings, conditions associated with a thymoma was screened for and she was found to have a positive anti-acetylcholine receptor antibody titre of 1.76 nmol/L. Flow cytometry of the bone marrow showed B cell aplasia and the possibility of Good's Syndrome was raised. She had evidence of hypogammaglobulinaemia, with an IgG level of 4.83g/L, IgA of 0.27 g/L and IgM of<0.2g/L, consistent with Good's syndrome.
Results: She continued to require red cell transfusions to maintain an adequate haemoglobin level. She eventually agreed for a thymectomy 9 months after the initial diagnosis. She received red cell transfusions and intravenous immunoglobulin prior to surgery. The histology of the anterior mediastinal mass was consistent with a WHO type AB thymoma. She was commenced on immunosuppressive therapy with cyclosporine as she remained transfusion dependent despite the thymectomy. After 8 months of immunosuppressive treatment post thymectomy, she is currently transfusion dependent for 9 months.

Figure 1.

Summary/Conclusion: Good's syndrome which was associated with the thymoma was important to exclude in this patient prior to her thymectomy to reduce the risk of post surgical infective complications. Given that infective complications were the major cause of death in a case series, I believe that thymoma-associated PRCA should be screened for Good's syndrome prior to their surgery to improve patients clinical outcome.

PB1842

FOUR CASES OF FANCONI ANEMIA WITH VARIABLE ABNORMALITIES

E. Turkkan*

Pediatric Hematology, Okmeydanı Research and Training Hospital, Istanbul, Turkey

Background: Fanconi anemia (FA) is an autosomal recessive genetic chromosomal instability syndrome characterized by congenital malformations, hematological problems and predisposition to malignancies. FA can present a variety of congenital defects but invariably results in defective haemopoiesis, which is the major cause of morbidity and mortality. Numerous congenital abnormalities have been reported in approximately 75% of patients with FA, and the most common of these abnormalities are skeletal (radial ray, hip, vertebral bones, rib), skin dyspigmentation, short stature, abnormalities of the eyes (microphthalmi and strabismus), renal and genito-urinary tract abnormalities, microcephaly.
Aims: In this paper, four cases of FA patients between 7-18 ages (3 female and one male) with different skeletal, skin and hematologic abnormalities are presented.
Methods: All 4 cases had microcephaly, skin dyspigmentation, dysmorphic face appearance, There was 1 case with an unusual thumb polydactyly, and the remaining 3 patients had normal fingers. The extra thumb had nail, but no active motion. Thumb polydactyly is a common hand anomaly but its concurrence with FA is a very rare.
Results: Repeated complete blood cell counts indicated persistent mild thrombocytopenia; diepoxibutane and nitrogen mustard induced chromosome breakage testing on lymphocyte cultures were compatible with the FA and levels of fetal hemoglobin were increased in all of the patients.
Summary/Conclusion: The disease is a heterogeneous condition that can present with a variety of congenital defects. There have been conflicting reports about the severity and type of congenital malformations of the disease. Although diagnosis of FA should be verified by identification of chromosomal instability. Recognition of the numerous pathologies associated with FA is important in order to diagnose of the syndrome.

Chronic lymphocytic leukemia and related disorders – Biology & Translational Research

MONOCLONAL GAMMOPATHY AND HYPOGAMMA GLOBULINEMIA AS INDEPENDENT PROGNOSTIC FACTORS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A RETROSPECTIVE MONOCENTRIC EXPERIENCE

A. Corbingi, I. Innocenti, F. Autore, F. Morelli, D. Soldati, S. Sica, L. Laurenti*

Policlinco Agostino Gemelli Roma, Roma, Italy

Background: Chronic Lymphocytic Leukemia (CLL) is an indolent B-cell lymphoproliferative disorder. Several prognostic factors such as IGHV mutation status and chromosomal aberrations as trisomy 12, del11q, del13q or del17p have been detected so far. More recent genetic mutations such as BIRC3, SF3B1, NOTCH1 and TP53 stratifies the prognosis and outcome in CLL patients (pts). However all data above reported, because of expensive techniques and experience typical of big laboratories, are not available to all medical centers. Data concerning the presence of IgM, IgG paraprotein and their impact on natural history of CLL pts are controversial and contradictory while more certain seem to be the ones concerning hypogamma/CLL pts.
Aims: The aim of the study is to evaluate the prevalence and the outcome of monoclonal IgM/CLL, IgG/CLL and hypogammaglobulinemia compared with CLL pts with normal immunoglobulin (Ig) levels.
Methods: Our center collected from our CLL database 404 pts diagnosed from 1999 to 2017 with a baseline assessment of serum Ig, immunofixation, immunophenotype, chromosomal aberrations and clinical features evaluating time to progression (TTP), time to treatment (TTT) and overall survival (OS).
Results: Among 404 pts who met eligibility criteria, 26 pts had IgM/CLL, 33 pts had IgG/CLL, 46 pts had hypogamma/CLL and 299 showed no evidence of paraprotein. Median IgM level was 314 mg/dL in IgM/CLL, median IgG level was 1033 mg/dL in IgG/CLL, median gamma globulin was 7.8% in hypogamma/CLL. Median age was similar in all the groups. The worst time-dependent parameters such as TTP, TTT and OS were identified in the IgM/CLL group. These data probably reflect a more aggressive disease with more than 68% of pts in an advanced stage at diagnosis (Rai B/C).

Table 1.

	IgM/CLL	IgG/ CLL	Hypogamma	Absence of gammopathy
Patients	26	33	46	299
Age (y.o.)	69	63	68	66
Range	(48-82)	(45-86)	(39-89)	(26-85)
Gamma protein (%)	14.4	14.3	7.8	13.1
Range	(7.9-21.5)	(9.1-32)	(5.3-9)	(9-49.5)
IgM level (mg/dL)	314	52	19	54
Range	(31-3300)	(19-330)	(3-300)	(8-1443)
IgG level (mg/dL)	921	1033	535	954
Range	(464-2700)	(471-3939)	(320-1151)	(447-2382)
IGHV				
Mutated	11 (61%)	13 (62%)	17 (52%)	147(63%)
Unmutated	7 (39%)	8(38%)	16 (48%)	88 (37%)
CD38				
Positive	11 (58%)	15(52%)	15 (39%)	43 (16%)
Negative	8 (42%)	14(48%)	23(61%)	231 (84%)
Rai Stage				
A	8 (32%)	18(55%)	21 (45%)	173 (58%)
B	14 (56%)	12(36%)	17 (37%)	111 (37%)
C	3 (12%)	3(9%)	8 (18%)	15 (5%)
TTP (months)	3	19	16	28
TTT (months)	3	22	16	30
OS (months)	49.5	75	72	65

Summary/Conclusion: This study highlights the frequency of clonal IgM, IgG and hypogammaglobulinemia in CLL patients. Among the 4 groups, IgM/CLL group seems to have the worst outcome which proved to be a negative prognostic marker in newly diagnosed CLL patients.

PB1844

THE POSSIBLE ROLE OF TLR2 AND TLR9 RECEPTOR DYSFUNCTION IN THE PATHOGENESIS AND PROGRESSION OF CHRONIC LYMPHOCYTIC LEUKEMIA

A. Drobiecki[1], A. Szymczyk[2,*], A. Bojarska-Junak[3], A. Szymańska[2], W. Tomczak[4], J. Roliński[3], I. Hus[2]

[1]Department of Hematology and Bone Marrow Transplantation, Cancer Centre in Kielce, Kielce, [2]Independent Clinical Transplantology Unit, [3]Chair and Department of Clinical Immunology, [4]Chair and Department of Haematooncology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, Poland

Background: Recent data indicate a significant role of antigenic stimulation in chronic lymphocytic leukemia (CLL) development. It has been suggested that severe, symptomatic infections of bacterial and viral etiology can initiate immune disorders leading to the development of CLL. A special role is attributed to infections of the respiratory tract of bacterial etiology, especially those with *Streptococcus pneumoniae*. The induction of a humoral response against the pneumococcal sheath of antigens depends on the B-cell receptor (B-cell receptor) and receptors recognizing pathogen-associated molecular patterns (PAMPs), which also include Toll-like receptors (TLRs), especially TLR4 signaling pathway with the synergistic effect of ligands for TLR2 derived from the cell wall of the pathogens and TLR9, which recognizes fragments of nucleic acids.
Aims: The aim of the study was to evaluate the relationship between the expression of TLR2 and TLR9 responsible for the recognition of *Streptococcus pneumoniae* antigens and prognostic factors, treatment free survival (TFS) and the incidence of infectious complications in patients with CLL.
Methods: The study group consisted of 119 patients aged 49-87 with newly diagnosed CLL. Expression of the studied receptors was assessed by flow cytometry on CD19+ lymphocytes B and CD14+ monocytes with the use of monoclonal antibodies: FITC antihuman CD282 (TLR2) and PE Rat anti-Human CD289 (TLR9).
Results: In patients with CLL percentages of B lymphocytes expressing TLR2 and TLR9 were significantly lower compared to the control group (Md 0.38% *vs* 1.58%, p<0.05) and Md 0.6% *vs* 16.84%; p<0.01, respectively). The lower percentage of CD19+/TLR2+ and CD19+/ TLR9+ cells was associated with unfavorable prognostic factors (deletion of 17p and/or deletion of 11q, ZAP-70 and CD38 expression). Percentages of CD14+/TLR9+ monocytes were lower in the group of patients with advanced disease stages according to the Rai classification, CD38 and ZAP-70 expression and unfavorable cytogenetic aberrations. Percentages of CD14+/TLR2+ cells were lower in CD38-positive and ZAP-70-positive patients. There was also a significantly lower percentage of CD19+/TLR9+ B cells and CD14+/TLR9+ monocytes in patients requiring treatment during observation in comparison with the group of patients with no need to start the therapy. TFS was significantly longer in patients with a higher percentage of monocytes expressing TLR9 (25 *vs* 20 months, p<0.05). The percentage of B lymphocytes expressing TLR9 was significantly lower in patients with recurrent infections. In addition, the reverse correlation between the percentage of monocytes expressing TLR2 and TLR9 and the overall incidence of infections and the incidence of the bacterial infections was observed. Moreover, in patients who required IgG supplementation, the percentages of monocytes CD14+/TLR9+ and lymphocytes CD19+/TLR9+ were significantly lower compared to the patients without the need for supplementation (p<0.05).
Summary/Conclusion: The presented data suggest that the reduced expression of TLR2 and TLR9 might be involved in CLL pathogenesis and progression. One of the potential mechanisms in which the aberrant expression of TLR2 and TLR9 may affect the development and progression of CLL is the increasing susceptibility to infections that from one side are one of the most important causes of morbidity and mortality in patients with CLL, and on the other side may contribute to the progression of leukemia.

PB1845

DETECTION OF MEASURABLE RESIDUAL DISEASE BY NEXT-GENERATION SEQUENCING IN PAIRED BLOOD AND BONE MARROW SAMPLES FROM PATIENTS WITH LYMPHOID MALIGNANCIES

D. Miklos[1], L.W. Lee[2], B. Crossley[2], L. Muffly[1,*]

[1]Stanford Hospitals and Clinics, Stanford Medicine, Stanford, [2]Translational Medicine, Adaptive Biotechnologies, Seattle, United States

Background: Cytomorphologic examination of bone marrow samples from patients with leukemia has been a hallmark of clinical management for decades. More recently, measurable residual disease detection (MRD) has become an important tool for the monitoring of patients with lymphoid

malignancies during their course of therapy and for early detection of impending relapse. Conventionally in the USA, bone marrow is collected and analyzed by multiparametric flow cytometry (mpFC) to evaluate MRD status. The sensitivity of mpFC varies but generally is in the range of 10^{-3} to 10^{-5} if one million cells are subjected to analysis. More recent molecular methods such as next-generation sequencing (NGS) allow for more sensitive detection of MRD at 1 in 10^{-6} if one million cells are analyzed. Thus, for the same number of cells analyzed NGS is approximately 10-100 times more sensitive than flow cytometry. The higher sensitivity of NGS raises the possibility that peripheral blood (PB) samples with an overall lower total tumor burden than bone marrow may nevertheless be suitable for MRD tracking by NGS in certain lymphoid malignancies.
Aims: We conducted a comparative analysis of the levels of MRD by NGS of paired PB and bone marrow samples among patients with lymphoid malignancies in order to determine concordance of MRD between marrow and PB, as well as the sensitivity and specificity of tracking MRD in the PB by NGS.
Methods: Forty-seven paired marrow and PB samples were obtained from 33 patients with lymphoid malignancies: 20 with acute lymphoblastic leukemia (ALL), 11 with chronic lymphocytic leukemia (CLL), and 2 mantle cell lymphoma patients. Genomic DNA was extracted from pre-treatment bone marrow samples and Adaptive Biotechnologies' NGS MRD assay was used to evaluate the complete B and/or T cell repertoires in order to identify dominant sequences appropriate for MRD tracking. Subsequently, paired PB and bone marrow samples were obtained from this patient cohort and evaluated for MRD via NGS.

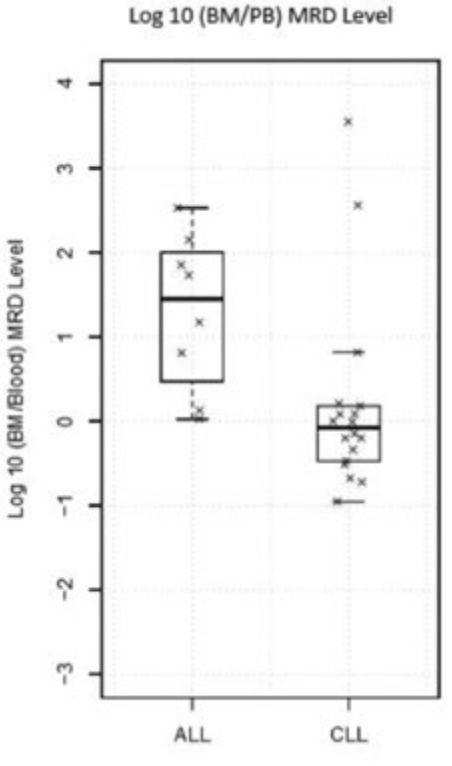

Figure 1.

Results: Twenty of 47 paired samples were negative for MRD in both bone marrow and PB. 27 of 47 paired samples were positive for MRD in the bone marrow; 23 of these were also positive for MRD in the corresponding blood sample. When compared to bone marrow, the sensitivity of detection in PB for ALL is 75% and for CLL is 88.9% with a specificity of 100% for both. Comparison of the MRD levels from PB and bone marrow for the 27 MRD positive cases generated a Lin's concordance coefficient of 0.92. Overall, MRD levels in the marrow were a median of 1.2 times higher than MRD in levels in the PB. Using the criterion of a one hundred fold difference between bone marrow and PB (roughly corresponding to an average difference in sensitivity of mpFC and NGS), 91.5% of the paired samples demonstrated concordance between PB and marrow MRD NGS results. The median ratio of marrow to PB MRD differed significantly between diseases (Marrow: PB MRD of 0.8 in CLL and 28.3 in ALL), Wilcoxon p value=0.007, see figure. Individual cases with discordant MRD results will be described in detail in the formal presentation.

Summary/Conclusion: Monitoring of MRD levels via NGS of the peripheral blood over time may provide an alternative to more invasive bone marrow aspiration and mpFC analysis in patients with lymphoid malignancies. Confirmatory prospective studies of PB MRD monitoring by NGS in patients with lymphoid malignancies are warranted.

PB1846

AGE-RELATED BACH2/PRDM1 GENE EXPRESSION ALTERATIONS IN T AND B LYMPHOCYTES FROM CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS AND AGE-MATCHED HEALTHY DONORS

P. De Silva[1,2,*], V.L. Dang Chi[1,2], S. Garaud[1], B. Stamatopoulos[3], C. Gu-Trantien[1,4], H. Duvillier[1], J.-N. Lodewyckx[1], K. Willard-Gallo[1], C. Sibille[5], D. Bron[2]

[1]Molecular Immunology Unit, [2]Hematology, [3]Laboratory of Clinical Cell Therapy, [4]Institute of Medical Immunology, [5]Department of Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

Background: With advancing age, especially after the six decade of human life, the probability of developing cancer, including malignant hemopathies such as chronic lymphocytic leukemia (CLL), increases. This happens due to progressive decline in immunosurveillance that favors tumor escape and progression in elderly. With increasing age, the human body is more prone to genetic and epigenetic changes that are important contributing factors in the pathogenesis of cancer by negatively impacting on immune cell function. Moreover, these genetic or epigenetic modifications associated with aging could also impact on tumor suppressor genes (TSGs).
Aims: We previously reported a correlation between 6q deletion and progression into a T cell lymphoproliferative disease, identifying the *BACH2* gene as a candidate TSG. We thus examined the expression of specific transcription factors; BACH2/PRDM1 in T and B cells for their potential role in immunosenescence.
Methods: Peripheral blood mononuclear cells were isolated from whole blood obtained from untreated B-CLL patients (n=41) and age-matched healthy donors (HD; n=60) using Lymphoprep (Stemcell Technologies) density gradient centrifugation. T cells ($CD3^+CD4^+$, $CD3^+CD8^+$) and B cells ($CD19^+$) were purified (purity between 95%>99%) using magnetic isolation for subsequent molecular analyses. *BACH2*, *PRDM1 and CDKN2A (p16INK4A)* transcripts were quantified using RT-qPCR. *BACH2* and *BLIMP1 (PRDM1)* protein expression were examined by Western blotting. To measure ß-galactosidase activity, we used flow cytometry with Fluorescein-di-beta-D-galactopyranoside (FDG) as a substrate for beta-galactosidase. T and B cell apoptosis was analyzed after intracellular oxidative stress-inducing etoposide treatment in both populations.
Results: *BACH2* gene expression in the HD groups is significantly down-regulated in $CD4^+$, $CD8^+$ T cells and $CD19^+$ B cells from the older HD group (p=0.0012; 0.0045 and 0.0367, respectively). *BACH2* expression further reduced in $CD4^+$, $CD8^+$ T cells and $CD19^+$ B cells from CLL patients compared to age matched-HD (p=0.001;<0.0001 and 0.0043). *PRDM1* gene expression inversely correlated with *BACH2* in $CD4^+$, $CD8^+$ T cells and $CD19^+$ B cells (r=0.61; 0.71 and 0.65, respectively). Moreover, *PRDM1* was as expected significantly upregulated in $CD4^+$ and $CD8^+$ T cells (p=0.0034; p=0.0017) from B-CLL patients but not in their leukemic-B cells. Western blotting analysis demonstrated that *BACH2* and *BLIMP1* (*PRDM1*) protein expressions in the T and B cell subpopulations significantly correlated with transcript expression. We further studied correlation between BACH2 expression and other senescence markers, such as *p16INK4A* (encoded by *CDKN2A* gene) and ß-galactosidase in both T cells and B cells. *CDKN2A* gene expression inversely correlated with BACH2 in $CD4^+$, $CD8^+$ T cells and $CD19^+$ B cells (p=0.036; 0.025 and 0.043, respectively). ß-galactosidase activity showed a twofold increase compared to the BACH2 deficient lymphocytes ($CD4^+$, $CD8^+$ and $CD19^+$) in older HD compared to young. We also observed a strong correlation between age-related BACH2 down-regulation and a decrease in $CD4^+$ T cell and $CD19^+$ B cell apoptosis (p=0.0127 and 0.0218 respectively).
Summary/Conclusion: Our data suggest that downregulation of *BACH2* and upregulation of *PRDM1* expression in major lymphocyte subsets from CLL patients and older healthy controls are significantly correlated with the aging immune cells and could be part of the resistance to apoptosis in B-CLL cells.

A. Rodriguez[5], A. Medina[6], M. Fernández[7], V. Martín[7], E. Rios[8], C. Chic[9], M.J. Berruezo[10], C. Benet[11], M.A. Ruíz[12], M. Montagud[13], I. Navarro[14], A.I. Teruel[3], M.J. Terol[3], J.F. Chaves[1]

[1]Genotyping and Genetic Diagnosis Unit, [2]Hematology, INCLIVA Institute, [3]Hematology, Clinic University Hospital, Valencia, [4]Hematology, University Hospital Carlos Haya, Malaga, [5]Hematology, University Hospital Virgen de la Macarena, Sevilla, [6]Hematology, Hospital Costa del Sol, Malaga, [7]Hematology, University Hospital Reina Sofía, Córdoba, [8]Hematology, University Hospital Virgen de Valme, Sevilla, [9]Hematology, Hospital Infanta Margarita, Córdoba, [10]Hematology, University Hospital de Jerez, Jerez de la Frontera, [11]Hematology, University Hospital Arnau de Vilanova, [12]Hematology, University Hospital San Francisco de Borja, Valencia, [13]Hematology, Hospital de Vinaroz, Castellón, [14]Hematology, Hospital de Sagunto, Valencia, Spain

Background: The mutational status of *immunoglobulin heavy variable* (*IGHV*) genes has been established as one of the most reliable prognostic markers in CLL. Unmutated CLL (U-CLL), is associated with an aggressive phenotype and shorter survival than patients with less than 98% identity to germ line ("mutated CLL"). The molecular mechanisms underlying these subtypes are incompletely understood. Human immunoglobulin (Ig) genes are diversified in mature B cells by distinct processes known as Ig heavy chain class switch recombination and Ig variable region exon somatic hypermutation. These DNA modification processes are initiated by activation-induced cytidine deaminase (AID), a DNA cytidine deaminase predominantly expressed in activated B cells. In malignant lymphoid tumors of germinal origin, activation-induced deaminase appears to be pathogenic. More recent work has suggested that WGCW sites, and in particular certain AGCT sites, may play a special role as AID "entry sites" that not only mutate at high frequency, but also facilitate further mutations close to the site of the original mutation and throughout the V region.
Aims: In this study, we investigated the frequency and mutation status of *IGHV* in a cohort of 489 CLL patients from Mediaterranean region of Spain. We also analyzed the relationship between the number of WGCW hotspots in the germline V-region and the observed mutation frequency in this cohort.
Methods: Initial FASTA files with IGH (BIOMED-2) sequences from 489 patients sequenced by Sanger were converted to FASTQ with simulated qualities to test our IGH NGS-designed analysis pipeline. Reads are aligned against IGHV, IGHD and IGHJ genes from IMGT References Database using BWA mem, and then mapping statistics are generated to select the 10 more represented alleles for each sample. IGHV and IGHJ genes are determined and compared with IMGT-VQuest results. Homology and mutational status in IGHV is achieved by performing local alignment (EMBOSS Water) against the candidate alleles, and those with a homology percent less than 85 are discarded (30 out of 489 samples). All the sequences were productive. IGHD allele is determined extracting CDR3 according to IMGT Unique numbering recommendations and then the subset is aligned against IGHD alleles using BLAST, choosing the hit with higher score. WGCW motif count was performed on each sequence using custom R scripts. Secondary AID hotspots (WRC, GYW, SYC, GRS) were quantified separately not involving possible overlappings with WGCW motif.
Results: The mean number of AID hotspots (WGCW) in the germline V region of U-CLL cases (11 motifs), is significantly higher than for M-CLL patients (6,8 motifs) whereas in the secondary hotspots we could not find any significative differences (Fig1.a). We compared the mutational status of each V gene, to the mean number of WGCW motifs (vertical axis) in the corresponding germline V region, and contradictory, V regions with more WGCW motifs are more likely to be U-CLL (Fig1.b). All of patients with IGHV1-69 rearrangement have a mean mutation frequency of 0.35%, and paradoxical, this germline sequence contains a mean of 13 WGCW sites; whereas cases expressing IGHV3-15 or IGHV3-72 clones, are commonly mutated, with a mean mutation frequency of 6% and 5.2%, respectively, and contains less hotspots (5-7 WGCW sites) (Fig1.c).
Summary/Conclusion: We confirm a geographical-dependent leukaemic repertoire and reproduced previous studies which observed both V-regions with more WGCW hotspots in the germline sequences are more likely to be unmutated and this relationship is restricted to WGCW hotspots.

PB1848

QUADRANT ANALYSIS OF DRUG APPROVAL AND EMERGING TREATMENT TRENDS IN CHRONIC LYMPHOCYTIC LEUKEMIA-A RETROSPECTIVE STUDY ON PIVOTAL CLINICAL TRIALS

M. Chhikara[1,*], D. Mazumder[2], R. Tyagi[2]

[1]Oncology, SmartAnalyst Inc., New York, United States, [2]Real World Evidence, SmartAnalyst India Pvt Ltd, Gurgaon, India

Background: CLL is an incurable lymphoproliferative disease where treatment landscape has rapidly evolved with the approval of several novel oral targeted therapies across various settings. Most settings are unique based on baseline risk profiles of the patients (pts). In absence of head-to-head trials, it is challenging to compare treatments for researchers and physicians as different treatments are approved in different patient segments. There are important prognostic and predictive parameters that guide the therapy choices and outcomes. Using appropriate methods, CLL can be classified into three risk groups differing in efficacy and safety outcomes that can guide patient selection for specific therapies.
Aims: The primary aim of the study is to evaluate risk adjusted relative scores of efficacy and safety for approved drugs in CLL.
Methods: The study used data from SMARTOncology Database (SmartAnalyst Inc., USA) developed for internal research purposes using public sources such as ClinicalTrials.gov, publications, company websites and FDA labels. The study derived patient risk scores based on prognostic variables such as median prior lines of therapy, ECOG, staging, co-morbidities to categorize pts into low, medium and high-risk groups. This study also considered pts with 17p deletion (del)/TP53 mutations (mut) as high-risk pts. For the trials where 17p del/TP53 mut information was missing, the risk categorization was done based on above prognostic factors. The risk-adjusted relative scores of efficacy and safety endpoints (ORR, mPFS and grade ≥3AEs) were derived based on patient risk scores to design the quadrants. The individual quadrants were designed for ORR and safety endpoints and for mPFS and safety endpoints. The X-axis represented efficacy from 'Low-High' and the Y-axis represented safety from 'Low-High'. The adjusted relative score for each drug was plotted and collectively rated based on the position of the drug in the respective quadrant. The drugs represented in the quadrant of 'High efficacy' and 'High safety' can also be called as "quadrant of effectiveness". The analysis was carried out separately for the drugs approved in frontline and relapsed/refractory (RR) settings.
Results: The study revealed that Ibrutinib and Ofatumumab+chlorambucil were observed in the quadrant of effectiveness based on ORR and safety endpoints, while Ibrutinib and Obinutuzumab +chlorambucil were observed in the quadrant of effectiveness based on mPFS and safety endpoints in frontline. The study revealed that Ibrutinib has the most promising efficacy and safety as compared to other novel drugs. In RR setting, Ibrutinib and Venetoclax were observed in the quadrant of effectiveness based on both ORR and safety endpoints as well as mPFS and safety endpoints. While Idelalisib+Rituximab represented relatively lower effectiveness compared to the other drugs. The study also revealed that Ibrutinib and Venetoclax were the most promising drugs in RR setting compared to others.

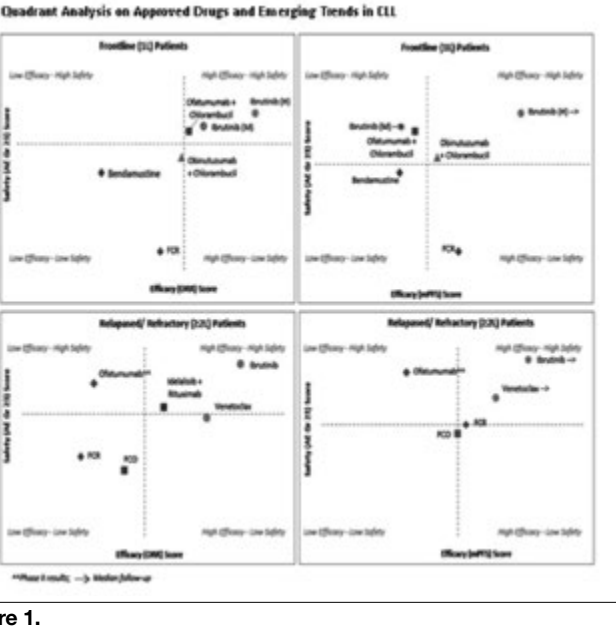

Figure 1.

Summary/Conclusion: Despite multiple approvals of novel therapies in CLL, unmet need still persists. These approved therapies may be tested in wide range of patient settings. The current analysis suggests that if the therapies were observed in the quadrant of effectiveness the probability of approval may increase and so does the broader applicability across multiple settings. Further analysis will help in understanding the correlation of differences in patient characteristics and cytogenetic testing practices on treatment decisions and outcomes.

UNCLASSIFIABLE ISOLATED MONOCLONAL HYPERLYMPHO CYTOSIS: COMPREHENSIVE DESCRIPTION OF A RETROSPECTIVE COHORT

M. Degaud[1,*], L. Baseggio[1,2], B. Grange[1], D. Manzoni[1], S. Huet[1,2], E. Callet-Bauchu[1,2], A. Traverse-Glehen[2,3], H. Ghesquières[2,4], G. Salles[2,4], P. Sujobert[1,2]

[1]Laboratoire d'hématologie, Hospices Civils de Lyon-Centre Hospitalier Lyon Sud, [2]INSERM 1052, CNRS 5286, Université Claude Bernard-Faculté de Médecine Lyon Sud Charles Mérieux, [3]Laboratoire d'anatomopathologie, [4]Service d'hématologie clinique, Hospices Civils de Lyon-Centre Hospitalier Lyon Sud, Pierre Bénite, France

Background: With the emergence of targeted therapy, the precise classification of B-cell disorders has become critical. Indeed, a B-cell disorder presenting an altered TP53 gene should be treated by BCR inhibitors if it is a chronic lymphocytic leukemia (CLL), but by immunochemotherapy if it is a marginal zone lymphoma (MZL). For B-cell disorders without tumoral syndrome, the diagnosis relies only on the analysis of circulating lymphocytes. Most of the time, cytologic, phenotypic, cytogenetic and molecular data allow to correctly classify those patients according to the WHO classification. However, for a few patients, the comprehensive analysis of tumoral cells doesn't allow to retain a precise diagnosis.
Aims: The aim of this study was to better characterize the clinical presentation and outcome of patients with absolute lymphocytosis that cannot be precisely classify in the WHO classification.
Methods: We describe a monocentric retrospective cohort of patients presenting a lymphocyte count >5 G/L, but without clinically detectable tumoral syndrome. We excluded patients with evident diagnosis according to the WHO classification, such as CLL, mantle cell lymphoma, or splenic MZL. Overall, 18 patients fulfilling these criteria were identified between 1999 and 2015 in our tertiary care center. We have reviewed cytological, phenotypical, cytogenetical and molecular features of these patients. For 8 patients, a panel of 94 genes was sequenced.
Results: Most patients were old (median age: 79 year-old) and without clinical signs or cytopenia. Cytological and phenotypical features were intermediate between CLL and MZL (notably with the RMH score<3 and positive CD5 staining for 16/18 cases). Cytogenetic analysis highlighted a chromosome 12 trisomy for 13/18 cases, and other alterations found in CLL (17p deletion, 13q deletion). Sequencing of the gene panel highlighted molecular anomalies found in both CLL and MZL, with frequent mutations of TP53 (3/8 patients). The disease seems relatively indolent as 5/18 patients were treated after a median follow-up of 4 years.
Summary/Conclusion: We have identified a group of patients presenting biological features intermediate between CLL and MZL. These B-cell disorders are characterized by a high frequency of chromosome 12 trisomy and a relatively indolent evolution. As these cases cannot be definitively classified in a category of the WHO classification, the choice of the first line treatment might be problematic: for patients presenting a TP53 alteration, if they are classified as CLL, ibrutinib is indicated, but this is not the case if they are classified as MZL. Other case series are mandatory to precise the optimal treatment of this B-cell disorder with intermediate features between CLL and MZL.

PB1850

TARGETING THE INTERPLAY BETWEEN HSP70 (HEAT SHOCK PROTEIN OF 70KDA) AND HSF1 (HEAT SHOCK FACTOR 1) IN CHRONIC LYMPHOCYTIC LEUKEMIA

F. Raggi[1,2,*], F. Frezzato[1,2], V. Martini[1,2], F. Severin[1,2], V. Trimarco[1,2], A. Visentin[1,2], E. Scomazzon[1], M. Facco[1,2], G. Semenzato[1,2], L. Trentin[1,2]

[1]Department of Medicine Hematology and Clinical Immunology Branch, Padua University school of Medicine, [2]Venetian Institute of Molecular Medicine VIMM, Padua, Italy

Background: Chronic Lymphocytic Leukemia (CLL) is a heterogeneous disease characterized by the accumulation of clonal B cells in peripheral blood, bone marrow and lymphoid tissues[1]. Recently, we demonstrated that two proteins endowed with cytoprotective activity, the Heat Shock Protein of 70kDa (HSP70) and the Heat Shock Factor 1 (HSF1), are overexpressed in CLL B cells and correlated to poor prognosis. HSF1 is regulated by a fine balance of activatory/inhibitory phosphorylations mediated by kinases belonging to RAS-triggered pathways[2]. Thanks to our previous study[3], we hypothesize a model by which HSF1 is regulated through different RAS pathways, thus helping to gather information and dissect these networks in CLL. Particularly, the activation of RAS/PI3K/AKT is able to up-regulate HSP70 production, while the activation of the RAS/RAF/MEK/ERK pathway leads to the down-modulation of HSP70 expression.
Aims: Since we found that HSP70 and HSF1 were overexpressed in CLL and considering the pro-survival role of HSP70/HSF1 axis in cancer[4], we are herein aimed at testing their druggability in CLL neoplastic B cells. In this context, we used molecules whose activity simultaneously affected the two RAS-mediated pathways, inhibiting AKT and activating ERK to the final purpose of down-modulating HSP70.
Methods: Freshly isolated leukemic B cells from therapy-free CLL patients were cultured in RPMI 1640 supplemented with antibiotics and 2% FBS and treated separately with: 40μM Resveratrol (a phenol); 10, 20 and 30μM Pterostilbene (a natural analogue of Resveratrol); 10, 50 and 100μM Triacetyl Resveratrol (a Resveratrol prodrug displaying superior bioavailability to Resveratrol); 5, 10 and 20μM Honokiol (a poly-phenolic compound whose action resemble that of Resveratrol). Apoptosis was evaluated after 24 hours by Annexin V/Propidium iodide flow cytometry test and by the presence of cleaved PARP in Western blotting.
Results: We found that in CLL, Resveratrol, or molecules with the same mechanism of action (*i.e.* inhibiting AKT activity and enhancing that of ERK) are able to induce apoptosis of neoplastic B cells in a dose-dependent manner. Particularly, we observed apoptosis after treatment with: 40μM Resveratrol (54±20% of living cells *vs* untreated cells, 70±18%; p<0.01, paired Student's *t* Test); 10μM Triacetyl Resveratrol (65±8% of living cells *vs* untreated cells, 80±5%; p<0.01, paired Student's *t* Test); 20μM Honokiol (26±29% of living cells *vs* untreated cells, 77±8%; p<0.05, paired Student's *t* Test). Preliminary data on Pterostilbene show similar results.
Summary/Conclusion: HSP70 and HSF1 overexpression and correlation with poor prognosis in CLL patients underline their pivotal role in the regulation of leukemic B cell survival. For this reason, they represent interesting targets for anti-leukemic therapies. Of note, the use of molecules that simultaneously act at two different levels in the regulation of HSF1, and consequently of HSP70, should be considered in this field.

PB1851

ANALYSIS OF THE 3′UTR REGION OF THE NOTCH1 GENE IN CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

N. Bilous[1,*], I. Abramenko[1], A. Chumak[1], Z. Martina[2], I. Dyagil[2]

[1]Clinical Immunology, [2]Hematology, Research Center for Radiation Medicine, Kyiv, Ukraine

Background: *NOTCH1* mutations are associated with poor prognosis for chronic lymphocytic leukemia (CLL) patients. They are represented mostly by c.7541_754delCT deletion and, in the minority of cases, point mutations in the 3 UTR region of *NOTCH1. Both types of mutations* resulted in the removal of C-terminal PEST domain and deregulation of *NOTCH1*-dependent signaling pathways.
Aims: To evaluate the frequencies of mutations in the 3 UTR region of the *NOTCH1 in CLL patients in Ukraine and the distribution of* rs3124591 genotypes located in the amplified area.
Methods: Detection of mutations in the 3 UTR region of the *NOTCH1 was performed by* direct sequencing in *109 CLL patients in whom typical* c.7544_7545delCT mutation was not found. *IGHV* rearrangement were analyzed by IMGT/V-QUEST (Brochet *et al.*, 2008). Analysis of rs3124591 genotypes was performed using SNPstats tool (http://bioinfo.iconcologia.net/ snpstats/start.htm).
Results: Mutations in the 3 UTR region of the *NOTCH1 were revealed in 3 of 109 CLL patient (2.75%), all three among 92 cases with in-frame unmutated IGHV genes (5.4%).* Non-coding mutations were represented by 139390152A>G (*two cases*) and 139390145A>G (one case). *Two cases with* mutations were related to subset #1, and one case belonged to stereotyped subset #28a. In addition to previously revealed c.7544_7545delCT mutations in 34 CLL patients, four of eight cases of subset #1 and both cases belonging to subset #28a in our CLL cohort had *NOTCH1* mutations. The distribution of rs3124591 genotypes was as follows: CC genotype-22 cases (20.2%), CT genotype-47 cases (43.1%), and TT genotype-40 cases (36.7%). The spectrum of used *IGHV* genes was significantly larger in TT homozygotes than in carriers of CT and CC genotypes (; p=0.046). When in-frame unmutated *IGHV* rearrangements were analyzed, we found a reduced *IGHV*1-69 gene usage in carriers of TT genotype compared to carriers of CT and CC genotypes (14.7%, 38.5%, and 47.4%; p=0.023) and, on the contrary, more frequent *IGHJ4* gene usage (50.0%, 25.6%, and 21.1%; p=0.046). In addition, the frequency of "major" stereotyped subsets (according to Agathangelidis *et al.*, 2012) was higher in TT carriers compared to carriers of CT and CC genotypes (26.5%, 10.2%, and 5.5%; p=0.021). The number of N nucleotides inserted in the V_HD junctions in

unmutated *IGHV* rearrangements was significantly less in carriers of TT genotype than in carriers of CT and CC genotypes (5.28±0.74, 9.21±0.94, and 9.21±1.03, correspondingly; p=0.003). The HCDR3 length in carriers of TT genotype was significantly shorter than in carriers of others genotypes (18.88±0.71 a.a. *vs* 21.15±0.68 a.a. in CT genotype, and 21.36±1.13 in CC genotype; p=0.05). The comparison of CLL sequences with non-CLL sequences available from public databases showed that most cases that had HCDR3 homology with antibacterial or antiviral Ig clones were present in TT homozygotes (18.7% *vs* 6.5% in carriers of CT genotype and 0% in carriers of CC genotype; p=0.042). All CLL sequences homologous with autoreactive clones were revealed in carriers of TT (10.6%) and CT (8.7%) genotypes.

Summary/Conclusion: Our data confirmed current data on the association between the structure of the B-cell receptor and appearance of *NOTCH1* mutations. Some features of HCDR3 structure were identified in carriers of TT and CC genotypes. Taking into account data of Cao *et al.* (2014) on the functional significance of this polymorphism, it can be suggested that rs3124591 can influence on the selection of B-cell clones during early stages of CLL development.

Background: The *IGHV* (immunoglobulin heavy-chain variable region) gene mutational status is considered as an important prognostic factor in chronic lymphocytic leukemia (CLL), readily identifiable at diagnosis and independent of clinical stage or other prognostic factors. In addition, about 30% of CLL patients carry quasi-identical B-cell receptor (BCR) immunoglobulins that can be assigned to distinct stereotyped subsets. At present, information about *IGHV* repertoire and stereotyped BCRs (BCRSs) in CLL patients from South America is scarce.

Aims: In the current study, we have evaluated *IGHV* mutational status, gene usage and BCRSs in CLL patients from a multicenter study developed in the context of the Latin American Group of CLL.

Methods: Our cohort included 707 unselected CLL patients from Argentina (253), Brazil (276), Uruguay (99) and Venezuela (79) (413 males; mean age: 66.6 years, range: 27-105 years; Rai clinical stages: 0: 35.8%, I-II: 41.9%, III-IV: 22.3%). The study was approved by the local Ethics Committees of each Institution. All individuals provided their informed consent. PCR was performed on cDNA or gDNA using VH framework region 1 consensus family specific (VH1-VH6) or leader primers and antisense primers JH or Cμ. PCR products were analyzed on an automated DNA sequence analyzer. Sequence data were evaluated using IgBLAST and IMGT/V-Quest databases. *IGHV* sequences with ≥98% homology with respect to the germline counterpart were considered as unmutated. Stereotyped rearrangements and clusters were assigned by means of pair-wise alignment with known stereotyped sequences available from different public databases and using the new bioinformatics approach to identify major clusters.

Results: Our cohort showed over-representation of mutated cases, except for Brazilian patients. Concerning IGHV family usage, VH3>VH4>VH1 distribution was found in Argentina, while VH3>VH1>VH4 was present in the other countries. The most frequently used *IGHV* genes were *IGHV1-69* (12.3%), *IGHV3-23* (8.2%) and *IGHV4-34* (9.5%). *IGHV3-21* was present in 10% of Venezuelan patients but showed lower frequencies in Uruguayan (2%) and Brazilian (2.1%) cohorts and intermediate frequency in the Argentinean series (6.5%). BCRSs were present in 15.2% of total cases, 73.9% belonged to major clusters; three novel potential subsets were detected. As a whole, our cohort showed the following frequencies: cluster #1 (11; 1.53%), cluster #2 (9; 1.26%), cluster #4 (16; 2.23%) and cluster #8 (5; 0.70%). Argentinean series exhibited similar frequencies of clusters #1 (2.00%) and #2 (3.13%) than series previously reported. These clusters were under-represented or absent in the other studied countries, meanwhile cluster #4 was over-represented in South American cohort, particularly in Uruguay, followed by Argentina and Venezuela On the contrary, Venezuelan CLL patients showed very low percentages of major clusters (5.1%). A graphic showing cluster frequencies among different countries is shown in Figure 1. Interestingly, the analysis of the distribution between stereotyped and heterogeneous (not stereotyped) receptors showed that *IGHV3-21* gene was always included in the heterogeneous group in Brazilian and Venezuelan cohorts.

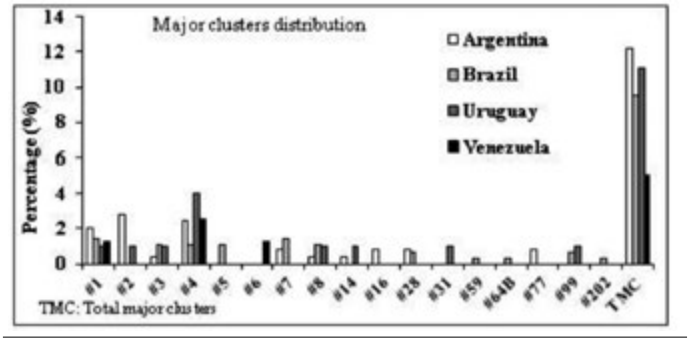

Figure 1.

Summary/Conclusion: Our results showed interesting differences compared to those from other geographical regions, highlighting the need for further research to understand the role of genetic background and environmental factors operating in CLL pathogenesis in the different geographical regions.

PB1853

A METHYL-CPG BINDING DOMAIN SEQUENCING STUDY SHOWED DYSREGULATED METHYLATION IN GENES INVOLVED IN CANCER, IMMUNITY, LYMPHOID DIFFERENTIATION AND MAJOR SIGNALING PATHWAYS IN ASIAN CLL

E. Lee[1,*], K. Jeon[1], M. Kim[1], J. Lee[1], H.-S. Kim[1], H.J. Kang[1], Y.K. Lee[1], S. Hwang[2]

[1]Laboratory medicine, Hallym Sacred Heart Hospital, Anyang, [2]Korea Research Institute of Bioscience and Biotechnology, Korean BioInformation Center, Daejeon, Korea, Republic Of

Background: CLL is the most common leukemia in Western countries, but rare in Asia including Korea (5/100,000 *vs* 0.5/100,000 per year), even though the incidence is increasing in Korea (0.5/100,000 in 1999-2001 to more than 1.2/100,000 in 2005-2010). Epigenetic research in Asian CLL is very rare and restricted to a few genes.

Aims: We hypothesized that CLL in Korea shows unique features compared to CLL in Western countries in terms of epigenetics. We performed Methyl-CpG Binding Domain Sequencing on CLL patients for the second time in the world and for the first time in Asia.

Methods: Nine Korean CLL patients and 5 age-matched Korean healthy individuals were included in the study. All the 9 patients showed TP53 mutation, and 1 patient showed IGHV hypermutation. One patient with IGHV hypermutation was excluded from the further analysis. B lymphoid cells were extracted using magnetic bead sorting technology. MBD-seq was performed using Invitrogen MethylMiner Methylated DNA Enrichment Kit and Illumina HiSeq 2000 platforms. The windows with FDR<0.01 were deemed as differentially methylated. The list of differentially methylated genes (DMGs) was then finally obtained. Functional enrichment analysis was performed by the clusterProfiler program with respect to Gene Ontology (GO) Biological Process and KEGG pathways, with significance criteria of p-value<0.05. For GO analysis, the options *minGSSize* of 20 and *maxGSSize* of 1,000 were applied.

Results: Our approach with MBD-seq enables a comprehensive genome-wide interrogation of differentially methylated regions (DMRs) in CLL.

There were more hypomethylated regions (2,062 windows) than hypermethylated regions (777 windows). Distal intergenic and intron regions contain the largest number of DMRs followed by promoter, 3'UTR and exon. As to the proportion of the DMRs, promoters contained the highest proportion of DMRs (around 0.08%), followed by 3'UTR, 5'UTR, downstream, distal intergenic region, exon and intron. A supervised hierarchical clustering clearly distinguished CLL patients from healthy individuals. The top forty differentially methylated genes (DMGs) include ERBIN, LINC00273, AGBL5, MIR4537, HCN1, LHPP, KIF16B, MYH3, LMNTD1 and CWH43. Immune process and cancer-related GO terms were dysregulated in CLL by DNA methylation either by hypo- or hyper-methylation. The dysregulated GO terms include Ras protein signal transduction, lymphocyte differentiation, immune system development, hematopoietic or lymphoid organ develoment, lymphocyte activation and positive regulation of apoptotic process. Dysregulated KEGG pathways included those that are directly related to immune process and cancer, mainly by hypomethylation. Most KEGG pathways were dysregulated by differential methylation in introns. The dysregulated KEGG pathway includes gastric cancer pathway, hepatocellular carcinoma pathway, CML pathway, breast cancer pathway Wnt signaling pathway, Ras signaling pathway, AML patway and transcriptional misregulation in cancer pathway. The reason why CLL pathway was not listed on top dysregulated KEGG pathways is simply because it is missing from KEGG pathway database content.

Summary/Conclusion: MBD-sequencing revealed that CLL patients have a distinct methylation profile from that of healthy individuals. Genes involved in cancer, immunity, lymphoid differentiation and major signaling pathways were dysregulated suggesting the role of dysregulated methylation in the pathogenesis of CLL. A further analysis will provide an important insight into the difference in methylation between Asian CLL and Western CLL.

DRUG SENSITIVITY SCREENING IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) FOR PRECISION CANCER THERAPY

D.B. Thimiri Govinda Raj[1,*], A. Cremaschi[2], S.S. Skånland[2], A. Gade[2], D. Wang[3], F. Schjesvold[4], G.E. Tjønnfjord[4], L.A. Munthe[4], K. Tasken[1]

[1]NCMM UIO and Oslo Univeristy hospital, [2]NCMM UIO, [32]Centre for Immune Regulation, Institute of Clinical Medicine, UiO, [4]Department of Haematology, Oslo University Hospital, Oslo, Norway

Background: Personalized cancer therapy is a rapidly developing field that includes predictive medicine, preventive medicine and various personalized or individualized therapies, *e.g.* labeled "precision medicine". One particular challenge with cancer is tumor heterogeneity evolving after the original clonal event. We focus on Chronic Lymphocytic Leukemia (CLL), Multiple Myeloma and Follicular lymphoma (FL), diseases currently considered incurable. Although current treatment regimens prolong life for patients, CLL eventually relapse. Current potential in using therapeutics against CLL include design of optimal treatment for individual patients based on characterization of the tumor and its intratumor heterogeneity as observed by whole genome sequencing. Efficient therapies require a personalized approach that combines targeting cancer cells and the tumor microenvironment by restoring the patient's own anti-tumor immunity. Another major limitation is that there exists no efficient approach to identify the most efficient drugs for each patient and also for different cancer stage. Using our drug sensitivity screening platform, we aim to address the limitation in identifying the efficient drugs for individual patients.

Aims: To introduce individualized treatment for patients, we aim to establish cell-based assays and a drug sensitivity platform. We aim to establish a pipeline for drug sensitivity screening in CLL. To complement the results from the drug sensitivity screening, we aim to perform phosphoflow analysis. We aim to complement our approach using xenografted mice. We propose to use the drug sensitivity screening platform for CLL individualized treatment with an effective combination of targeted therapies.

Methods: To define drugs that inhibit malignant B cell growth, we use the cell-based assays CellTiter-Glo® luminescent cell viability assay and CellTox™ green cytotoxicity assay. We have established culture settings that mimic the tumor microenvironment for CLL. We perform drug sensitivity screening with 517 drugs at 5 concentrations to select drug candidates and pathway inhibitors. Selected drug candidates will be further analyzed by bioassays and flow cytometry to assess effects on intracellular signaling (phosphoflow-based approach). We propose to use the drug sensitivity screening platform to identify and validate drug candidates for xenografting and precision medicine clinical trials.

Results: We established an experimental setting that mimics the tumor microenvironment for CLL (Thimiri Govinda Raj *et al.* EHA meeting abstract 2017 Haematologica 102, 711-711). We have performed drug screening on 20 patient samples with 517 drugs at 5 concentrations and are currently aggregating data and expanding the data set. We have also performed drug screening on healthy B cells as a control.

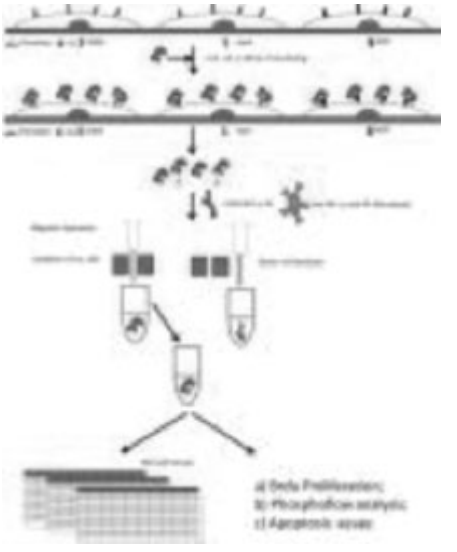

Figure 1.

Summary/Conclusion: Using our established CLL drug sensitivity screening at NCMM, we have performed drug screening on a number of patient samples. We aim to use a statistical approach to identify synergistic drug effects and validate the drug combinations experimentally. As a future perspective, we would combine machine learning strategies with the experimental drug screening strategies for the precision medicine clinical trials in other cancer settings.

MONOCLONAL B-CELL LYMPHOCYTOSIS IN GREEK POPULATION

Z. Saouli, C. Savopoulos, Z. Kontoninas, E. Ztriva*, S. Mpountola, G. Polychronopoulos, D. Milonas, A. Papadopoulos, A. Hatzitolios, G. Kaiafa

[1]st Propedeutic Department of Internal Medicine, AXEPA General University Hospital of Thessaloniki, Thessaloniki, Greece

Background: The diagnostic term monoclonal B-cell lymphocytosis (MBL) is used to characterise individuals with a circulating population of clonal B-cells, a total count of<5 x 10(9)/L, with no other features of a B-cell lymphoproliferative disorder. In the recent literature, it has been reported that circulating chronic lymphocytic leukemia (CLL)-like B cells can be detected using multicolor flow cytometry in 0.57%>12% of adults with normal lymphocyte counts.

Aims: As far as we know, this is the first study in Greek population, investigating the frequency of B-cell lymphocytosis in healthy individuals, trying to understand the prognostic factors that lead the occurence of MBL to evove into B-CLL.

Methods: We investigate the frequency of circulating monoclonal B cells in 815 healthy blood donors aged 30-70 years with no evident history of malignant disease and normal blood counts, who provided signed informed consent. We used flow cytometric analysis of CD19/CD5/CD79b/CD20/CD23/CD38 expression, while other parameters such as LDH, beta-2 microglobulin and C reactive protein were measured. Monoclonality was demonstrated by immunoglobulin light-chain restriction in all cases with CLL phenotype cells.

Results: The monoclonal CLL phenotype cells were detected in 1.6% of individuals, with a higher frequency in men (male-to-female ratio, 1.2:1) and elderly individuals (1.9% of 40- to 59-year-olds *versus* 4.0% of 60- to 89-year olds, P=0.01) which is within the framework of international studies.

Summary/Conclusion: Our study shows that a healthy percentage of the population in Greece, equal to 1.6% is bearing cells with CLL immunophenotype. The use of more extensive immunophenotype-order control or control of clonality seems to be a valuable prognostic factor for the occurence of monoclonal lymphocytosis, which may potentially evolve into B-CLL over time. Furthermore it is of great importance monitoring of these patients over time.

PB1856

THE EXPRESSION LEVEL OF CD 177 IS INCREASED IN PATIENTS WITH CHRONIC LYMPHOPROLIFERATIVE DISEASES AND MYELOID NEOPLASIAS

I. Krobinets*, N. Mineeva, A. Chechetkin, I. Bogdanova

FSBI "Russian research Institute of Hematology and Transfusiology of FMBA", St.Petersburg, Russian Federation

Background: CD177 is a glycosyl-phosphatidylinositol (GPI)-linked cell surface glycoprotein that has been shown to be a counter-receptor for platelet endothelial cell adhesion molecule-1 (PECAM-1). The interaction of CD177 with endothelial PECAM-1 supports neutrophil transendothelial migration. The phenotype of neutrophils can change in patients with malignant diseases of the hematopoiesis system. Several studies have confirmed the overexpression of neutrophil CD177 mRNA in polycythemia rubra vera, and two other myleoproliferative disorders, essential thrombocythemia and idiopathic myelofibrosis. It was also shown that CD177 is absent from neutrophils from paroxysmal nocturnal hemoglobinurea patients who are deficient in the ability to synthesize GPI linkages. Neutrophils from patients with chronic lymphoproliferative diseases (CLD) are characterized by increased CD54 expression, which is associated with cell activation. Little is known about the level of CD177 expression in patients with CLD.
Aims: The aim of the study was to evaluate and compare the expression level of CD 177 in donors and patients with CLD and myeloid neoplasias (MNP).
Methods: Blood samples of 144 healthy donors (group 1), 94 patients with CLD: chronic lymphocytic leukemia, Hodgkin's lymphomas, non-Hodgkin's lymphomas, multiple myeloma patients (group 2), and 61 patients with MNP, including chronic idiopathic myelofibrosis, chronic myelogenous leukemia, essential thrombocytosis, polycythemia vera patients (group 3) were included in the study. The mean age of patients in groups 2 and 3 was 64 years (range, 22 to 84) and 65 years (range, 21 to 81), respectively. Flow cytometry immunophenotyping analysis of CD 177 was performed using anti-human CD 177-PE, clone MEM-166. The level of CD177 expression was evaluated using mean fluorescence intensity (MFI) rate. MFI for CD 177-PE in group 1 was taken as the reference value.
Results: MFI for anti-CD 177-PE in group 1 was 31.8 to 149 (median 79.2). MFI in groups 2 and 3 was significantly higher (p=0.000001) than in group 1 (median 114, CI: 38.58-706.7 and median 131.1, CI: 40.39-360.2 *vs* median 79.2, CI: 41.25-136.37, respectively). No significant differences were revealed when MFI between groups 2 and 3 were compared (p=0.19).
Summary/Conclusion: The expression level of CD 177 is increased in patients with CLD and MNP compared to healthy donors. Neutrophils in patients with CLD have an activated phenotype, probably associated with a systemic inflammation. The presence of a chronic systemic inflammatory response may also explain the increase in CD 177 expression in patients with MNP.

PB1857

DEFINING A TECHNICAL WORKFLOW FOR GENE EXPRESSION PROFILING IN MRD+ CHRONIC LYMPHOCYTIC LEUKEMIA

A. Mora[1,2,*], R. Bosch[1,2], C. Cuéllar[1,2], R. Martino[2], J. Sierra[2], J. Nomdedeu[3], C. Moreno[1,2]

[1]Laboratory of Oncology/Hematology and Transplantation, IIB Sant Pau, [2]Department of Hematology, [3]Laboratory of Hematology, Hospital de la Santa Creu i Sant Pau, Autonomous University of Barcelona, Barcelona, Spain

Background: In CLL, the persistence of residual leukemic cells (MRD) after therapy is associated with poor outcome. Therefore, a better understanding of biological MRD characteristics would help to design newer and specific therapeutic approaches aimed at preventing clinical relapse. Nevertheless, working with a small amount of leukemic cells entails intensive labor to obtain enough material for gene expression profile studies. Here, we set forth an effective gene expression approach to study residual CLL cells.
Aims: The aim of this study was to set forth an effective gene expression approach to study residual CLL cells.
Methods: Leukocytes from fresh peripheral blood samples from 3 CLL patients were sorted based on MRD phenotype by multiparametric flow cytometry using a panel of 6 markers (CD43/CD5/CD19/CD81/ CD79b/ CD20). The quality and quantity of RNA isolated from two different inputs of cells $1x10^4$ and $5x10^5$ were compared by using two silica columns protocols (RNeasy Micro and RNeasy Mini, Qiagen). Furthermore, RNA amplifications were carried out according to two manufacture protocols (Ovation Pico SL and Ovation Pico WTA system, Nugen) to further compare the quality and quantity of cDNA obtained. A total of 3.5µg of cDNA obtained with Pico WTA System was labeled with Encore Biotin Module (Nugen) and hybridized with GeneChip Hybridization Wash and Stain Kit (Thermo Fisher) to GeneChip Human Gene 2.0 ST arrays (Thermo Fisher Scientific). The reproducibility of arrays resulting from the different amount of input cells was compared.
Results: RNA extracted from $1x10^4$ cells by RNeasy Micro and Mini Kit showed similar RNA Integrity Number (RIN), however, the amount of RNA obtained was higher using the RNeasy Micro Kit (mean: 116.0ng *vs* 80.0ng). Of note, the quantity of RNA obtained from $1x10^4$ cells was not significantly different from that isolated when the experiment was performed with a total of $5x10^5$ cells.
Furthermore, RNA samples obtained after using RNeasy Micro Kit were amplified with two different kits. The amount of cDNA as a result of RNA amplification was enough to proceed for an array experiment by using any of the two different protocols (see table 1). In terms of cDNA quality, the mean 260/280 ratios were in all cases above 1.8. Nevertheless, samples processed by Ovation Pico SL WTA showed smaller amplified fragments that were not observed in samples processed by Ovation Pico WTA system. Microarray data analysis of RNA extracted from $1x10^4$ and 5 $x10^5$ cells with Micro RNeasy and amplified with Ovation Pico WTA System, displayed a Pearson s correlation average of 0.964.

Table 1.

No. input cells	RNEasy Protocol	Mean RNA (ng, range)	Mean 260/280 ratio (range)	RIN range	Ovation WTA System	Mean cDNA (µg, range)	Mean 260/280 ratio (range)
10.000	Micro	116.6 (81.6-152.4)	1.4 (1.4-1.5)	2.4-3.1	Pico	8.6 (8.0-8.9)	1.9 (1.9-2.0)
					Pico SL	4.8 (4.6-5.1)	2.0 (2.0-2.0)
	Mini	80.0 (69.0-90.0)	2.7 (2.0-3.6)	2.6-3.2	-	-	-
500.000	Micro	117.6 (94.8-153.6)	1.8 (1.5-1.8)	4.9-7.4	Pico	8.8 (8.0-9.6)	2.0 (1.9-2.0)
					Pico SL	5.4 (5.2-5.6)	2.0 (2.0-2.0)
	Mini	411.0 (294.0-534.0)	1.9 (1.9-2.0)	2.7-3.3	-	-	-

Summary/Conclusion: By using the methodology herein presented, a total of $1x10^4$ leukemic cells were enough to obtain quantity and quality samples to perform array studies. Thus, this methodology can be useful to carry out gene expression profiling experiments involving MRD in CLL.

PB1858

EXPRESSION OF THE GENES OF THE MAIN RECEPTORS AND LIGANDS OF THE EXTERNAL PATHWAY OF APOPTOSIS IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC LYMPHOCYTIC LEUKEMIA DURING RFC THERAPY

S. Zakharov[1,*], A. Golenkov[1], A. Misyurin[2], E. Kataeva[1], M. Baryshnikova[1], T. Mitina[1], E. Trifonova[1], L. Vysotskaya[1], Y. Chernykh[1], E. Klinushkina[1], K. Belousov[1], Y. Finashutina[2], A. Misyurina[3], V. Misyurin[2]

[1]Moscow Regional Research and Clinical Institute, [2]"N.N.Blokhin Russian Cancer Research Center" Ministry of Health, [3]National Research Center for Hematology, Moscow, Russian Federation

Background: The expression of *FAS*, *TRAIL*, *TNFR2*, *DR4/5* and *DR3* are dysregulated in set of hematological malignancies. As result, apoptotic process in malignant cell is blocked due to lack of membrane apoptotic receptors. It may have negative clinical significance. We wanted to investigate the most important gene among listed genes.
Aims: To determinate clinical significance of *FAS*, *TRAIL*, *TNFR2*, *DR4/5* and *DR3* genes in primary B-CLL.
Methods: The expression level of *FAS*, *TRAIL*, *TNFR2*, *DR4/5* and *DR3* genes was studied in 23 patients with newly diagnosed chronic lymphocytic leukemia (B-CLL) before and after RFC-therapy. Multivariate regression analysis to perform clinical significance of each gene.
Results: According to multivariate regression analysis results, among these genes the *FAS* expression level has most value in clinical outcome. There are two conditions of *FAS* activity was observed-high expression level (median 7717%), and low (373%). Patients with high expression level of *FAS* has I-II stage of diesis (p=0.0205), lowest level of lymphocytes (p=0.0016) and highest level of erythrocytes (p=0.0159), and highest *TNFR2* and *TRAIL* expression level (p=0.0015 and p=0.0053, respectively). Patients

with low expression level of *FAS* has poorer clinical outcome (p=0.026).
Summary/Conclusion: Highest level of *FAS*, *TRAIL TNFR2* is associated with sensitivity oh B-CLL cells to induction of apoptosis. Moreover, it associated with better effectiveness RFC-therapy.

PB1859

THE IMPORTANCE OF MOLECULAR AND CYTOGENETIC ABERRATIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

E. Nazarova*, M. Sarpova, N. Minaeva, J. Suhorukova, I. Paramonov, E. Zotina, I. Dokshina, V. Shardakov

Kirov Research Institute of Hematology and Blood Transfusion, Kirov, Russian Federation

Background: Chronic lymphocytic leukemia (CLL) is the most common leukemia in adults and is characterized by clinical and biological heterogeneity. This heterogeneity is caused in some cases by structural aberrations in malignant cells, as evidenced by the presence of an abnormal karyotype. It is known that, in addition to cytogenetic aberrations, mutations of several genes involved in the pathogenesis of the disease and determining its differential prognosis are considered as important prognostic factors of CLL.
Aims: To identify the relationship of a number of immune response genes mutational status to the existing of numerical and structural changes in chromosomes in patients with CLL.
Methods: Sixty patients with CLL in the onset of the disease were examined, aged of 39 to 79 years (median-62 years). Men-37 (61.7%), women-23 (38.3%). All patients underwent FISH-diagnostics of nuclei of interphase bone marrow cells with DNA probes Kreatech FISH Probe. Genotyping of 20 polymorphic locus of the 13 immune response genes of peripheral blood leukocytes genomic DNA was carried out by polymerase chain reaction with allele-specific primers (single nucleotide polymorphism-SNP).
Results: The patients were divided into two groups. The first group included 26 (43.3%) patients with CLL who had no chromosomal abnormalities in the FISH analysis. The second group consisted of 34 (56.7%) patients with various cytogenetic aberrations in the form of monosomy, trisomy 12 and 13 chromosomes, del13q14, del11q22, del17p13. Comparing the obtained cytogenetic data with the results of detection of the immune response genes SNP, it was found that the presence of mutant alleles in the haplotypes of the Toll-like receptor (TLR) gene 9 (*TLR9*, T-1237C) and interleukin (*IL*) 2 (T-330G) is almost 14 (p=0.01) and 5 times (p=0.03), respectively, reduces the frequency of cytogenetic aberrations detection in CLL. Survival and proliferation of CLL cells are directly dependent on external factors-pathogen-associated (PAMPs) and damage-associated molecular patters (DAMPs). PAMPs and DAMPs initiate the development of the malignant process and its progression by stimulating the B-cell receptor and others, including TLRs. The TLR9 agonist-CpG-ODN upon binding to the receptor lead to activation of malignant CLL cells. The response of transformed cells to CpG-ODN is significantly different with IgVH-non-mutated and mutated CLL. In the first case, CpG-ODN protect CLL cells from spontaneous apoptosis and trigger their proliferation, whereas in case of mutated CLL, induction of programmed cell death is observed, which is reflected in a different clinical course of the disease. The study of this mechanism can provide additional information on the pathogenesis of CLL and, thus, leads to the development of new therapeutic strategies. Experimental dates have shown that CpG-ODNs induce proliferation, cytokine production and expression of the high-affinity receptor for IL-2 on malignant cells in CLL. IL-2 weakens the apoptosis of proliferating B cells and increases the frequency of their detection, which is used in the FISH analysis to increase their ability to stimulate the proliferation of T lymphocytes and their production of IL-4 and IL-5, which in the future can be used in immunotherapy for CLL.
Summary/Conclusion: Cytogenetic and molecular genetic studies in CLL are used to predict the course of the disease, and are one of the bases for the development of new targeted therapy drugs.

PB1860

BRAF MUTATION IN BOTH HAIRY CELL LEUKEMIA AND PAPILLARY THYROID CANCER IN THE SAME PATIENT

S. Mohamed*, M. Yassin, H. El Omri, F.I. Brahim, A. Nashwan, S. El Kiki

Hematology, HGH, DOHA, Qatar

Background: Hairy cell leukemia (HCL) is an uncommon form of mature B-cell neoplasm that originates from activated late B-cells. BRAF mutation associated with all cases of HCL, and 40% papillary thyroid (PTC) cancer.
Aims: BRAF mutation is well known finding in both HCL and PTC. Although the association of both cancers (HCL &PTC) with BRAF mutation is well established in the literature, up to our knowledge, this specific combination has not been previously reported in one patient.
Methods: 48-year old male, presented with bilateral hip pain found to have lytic bone lesions on both x-ray and MRI. His CBC were normal and abdominal US didn't show any splenomegaly.Bone marrow examination and flow cytometry results confirmed the diagnosis of HCL. The patient treated with cladrabine.Responded but continue to have fever, PET CT showed abnormal uptake in thyroid. PTC diagnosis confirmed underwent total thyroidectomy followed up with RAI 30 micori BRAF from both bone marrow biopsy and thyroid tissue which turn out positive in both.
Results: The case is unique for several reasons: 1- Patient did not present with pancytopenia, which is common at presentation and reported in 50% to 70% of patients with HCL; 2- He did not have splenomegaly. Splenomegaly is the most common physical finding in HCL and is reported in 70%>100% of cases; 3- HCL presenting as a lytic lesion is very uncommon. Most important the association of BRAF-positive papillary thyroid cancer. Finding of the activating point mutation in the kinase-encoding *BRAF* gene in all patients with classical HCL The mutation results in substitution of adenine for thymine at position 1799 in exon 15 of the BRAF that replaces Valine (V) by glutamate (E) at amino acid 600(*BRAF* V600E). Although the BRAF V600E mutation is frequently present in different neoplasms, including PTC. The *BRAF*V600E mutation is found to be highly specific for HCL and testing for this mutation is particularly useful in differentiating classic HCL from other B- cell neoplasm with overlapping features, such as HCL variant.
Summary/Conclusion: The presence of BRAF mutation in both papillary thyroid cancer and HCL may raise the possibility of common pathogenesis or BRAF maybe driving mutation

PB1861

CHARACTERIZATION OF IGHVDJ REARRANGEMENTS AND CHROMOSOMAL ALTERATIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M.A. Perera Alvarez[1,2,*], C. Bilbao Sieyro[1], A. Suarez Cabrera[1], Y. Florido Ortega[1], R. Stuckey[1], A. Saez Salinas[1], M.D.L.N. Saez Perdomo[1], S. Sanchez Sosa[2], J.M. Gonzalez Martin[3], D. V. Fiallo Suarez[1], M.T. Gomez Casares[1], T. Molero Labarta[1]

[1]Hematologia, Hospital Universitario de Gran Canaria Dr. Negrín, [2]Universidad de Las Palmas de Gran Canaria, [3]Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain

Background: The mutational status of *IGHV* genes is a well-established prognostic biomarker in chronic lymphocytic leukemia (CLL). Patients with unmutated *IGHV* genes experience a more progressive course of the condition and their survival is significantly reduced with respect to patients with mutated *IGHV* genes. Increasingly, studies are reporting the type and composition of IGH-VDJ rearrangements and defining specific stereotyped CLL subsets.
Aims: Analyze the IGH-VDJ rearrangements in a series of patients with CLL, determine their distribution and compare to results from similar studies. Group the rearrangements according to stereotype subsets and evaluate if a relation exists between subsets and other common genetic alterations in CLL.
Methods: The cohort included 49 patients diagnosed with CLL at the Hospital Universitario de Gran Canaria Doctor Negrín between 2014 and 2017. The characterization of IGH-VDJ rearrangements was determined from cDNA obtained from peripheral blood samples by Sanger sequencing using a 3130 Genetic Analyzer (Life Technologies, Carlsbad, CA). Chromosomal alterations were determined using FISH as part of routine diagnosis procedures. The statistical analyses were performed using R software.
Results: Of the 49 patients, 30 (61%) presented mutated *IGHV* genes *vs* 19 (39%) that were ummutated. With respect to the genetic alterations detected by FISH, 8% harbored del(11q), 10% del(17p), 18% +12, and 60% del(13q). There was a statistically significant association between del(11q) and unmutated *IGHV* genes (p=0.018, Fisher) and a marginally significant association between del(13q) and mutated *IGHV* genes ((p=0.075, Fisher), both in agreement with previously published results. The distribution of VH family usage and its association with the mutational status of IGHV was studied (Figure 1). The distribution of used VH families from highest to lowest incidence was IGHV3 (46.9%), IGHV4 (24.5%), IGHV1 (22.4%), IGHV5 (4.1%) and IGHV2 (2%), similar to that previously described in a series of Spanish CLL patients (González-Gascón *et al.*, 2013). The frequency of mutated *vs* unmutated for VH3 was 56.54% *vs* 43.5%, 45.5% *vs* 54.5% for VH1, and 75% *vs* 25% for VH4, respectively. These

frequencies were similar to those previously published with the exception of IGHV1 and VH3, for which the number of unmutated cases in IGHV1 was reported to be twice the number of mutated cases, with the opposite reported in VH3. With respect to the subfamily distribution (Figure 2), the highest incidence was VH3-30 (16%) followed by VH3-2, VH1-69 and VH4-59 (8% each). However, according to González-Gascón *et al*., the predominant subfamilies were VH1-69 and VH3-23 (18%) followed by VH4-34 (16%) and VH3-30 (12%). Table 1 shows the characteristics of the amino acids that constitute the HCDR3 region (quantity and proportion of hydrophilic/hydrophobic residues) and their relation with *IGHV* mutational status. We identified three cases that belonged to described stereotypes defined by Agathangelidis *et al.* (Blood, 2012): two were # 2 and one #202.

Table 1.

	MUTATED	UNMUTATED
MEAN AA NUMBER	15	18
HYDROPHILIC AA	24 (80%)	11 (57,9%)
HYDROPHOBIC AA	6 (20%)	8 (42,1%)
TOTAL	30	19

Table 1:Aminoacid distribution and its assotiation with the IgHV mutational status.

Summary/Conclusion: In general, our results are similar to those published on other Spanish CLL patients in terms of the IGHV family distributions, subfamilies and associations with other chromosomal alterations. The differences observed could be a result of the limited size of the patient series analyzed in this study. The different distribution of hydrophilic/hydrophobic amino acids among mutated and unmutated cases of CLL is a novel result and could possibly be associated with prognosis.

PB1862

EXPRESSION OF THE APOPTOSIS-RELEATED GENES IN PATIENTS WITH NEWLY DIAGNOSED CHRONIC LYMPHOCYTIC LEUKEMIA IN CLINICAL DATA CONTEXT

S. Zakharov[1,*], A. Golenkov[1], V. Misyurin[2], E. Kataeva[1], M. Baryshnikova[2], T. Mitina[1], A. Misyurin[2], E. Trifonova[1], L. Vysotskaya[1], Y. Chernykh[1], E. Klinushkina[1], K. Belousov[1], Y. Finashutina[2], A. Misyurina[3]

[1]Moscow Regional Research and Clinical Institute, [2]N.N.Blokhin Russian Cancer Research Center, [3]National Research Center for Hematology, Moscow, Russian Federation

Background: The given data of fundamental studies of apoptosis processes in B-CLL testifies about the complexity and variety of mechanisms affecting the kinetics of normal cells and tumor lymphocytes in this disease. It is important to study the severity of clinical manifestations of the disease depending on the expression of the genes that modulate apoptosis.
Aims: The aim of the study is to compare the activity of genes encoding apoptosis modulators, the cell cycle and cancer-testicular PRAME protein with clinical manifestations of the disease in primary patients with B-CLL.
Methods: The level of expression of the proapoptotic genes *FAS*, *TRAIL*, *TNFR2*, *DR4/5* and *DR3*, as well as the *HSP27*, *XIAP* genes, blocking apoptosis was determined in 23 patients with newly diagnosed chronic B-cell lymphocytic leukemia (B-CLL). In addition, expression of genes *TP53* and *P21* and cancer-testis gene *PRAME* are tested.
Results: According to the multivariate regression analysis, the *FAS* gene expression in the onset of the disease had the greatest impact on the clinical characteristics of the disease. In this connection, the patients were divided into groups with normal (group) and low gene level (group II). A low level of *FAS* expression (Me 387%) was associated with stage II disease (p=0,03), a large number of lymphocytes (p=0,001), fewer erythrocytes (p=0,08), and a lower level of *TNFR2* gene expression (p=0,08), high level of expression of *XIAP*, *HSP27*, *P21*. Overall, the anti-apoptotic potential in Group II patients was higher, which was accompanied by more pronounced clinical manifestations of the disease.
Summary/Conclusion: The increased anti-apoptotic potential of tumor lymphocytes in newly diagnosed B-CLL is accompanied by a larger tumor mass and greater clinical and hematological manifestation of the disease.

Chronic lymphocytic leukemia and related disorders – Clinical

PB1863

DISCORDANCE IN THE THRESHOLDS OF EARLY RELAPSE IN CLL GUIDELINES

V. Strugov*

Hematology Institute, National Almazov Medical Research Centre, Saint Petersburg, Russian Federation

Background: It is generally accepted that CLL patients with late disease progression after chemoimmunotherapy (CIT) remain chemosensitive and can be successfully retreated with the same regimen if they are still "fit" and no del17p/TP53mut is acquired. Accordingly, newer treatment options, such as Btk and PI3K inhibitors, are reserved to patients with so called "early relapse". As switch to newer drugs is often a difficult medical decision with consequences both to patients (different toxicity profile) and economy (higher treatment costs), a stringent evidence-based definition of "early relapse" is desirable.
Aims: We tried to analyze consistency and evidence base in the proposed thresholds of "early relapse" in different publicly available CLL guidelines.
Methods: PubMed and Google were searched for terms "CLL guideline" and "CLL recommendation". Relevant documents were collected from search results and analyzed for clinical guidance and references.
Results: Results are summarized in Table 1. All documents specified different timings of "early relapse" (namely, within 24, 24-36 or 36 mos after CIT). In two documents relevant clinical guidance was marked with II-III evidence level, however no prospective trials were cited with time-of-relapse based interventions or prespecified outcome analysis. Some guidelines didn't provide rational for a particular choice of threshold at all. Those documents, that gave references, cited MDACC (Keating *et al*., 1998; Keating *et al.* 2005; Tam *et al*., 2008; Keating *et al*., 2009; Tam *et al*., 2014), GCLLSG (Stilgenbauer *et al*., 2010; Cramer *et al*., 2015) or French Group (Fornecker *et al*., 2015). However, these sources appear to have serious limitations. For example, in publications from MDACC overall survival difference was calculated for a threshold of 36 mos *from the start* of FCR (that is, approx. 30 mos *post* CIT). Same issue applies to CLL8 data provided in Stilgenbauer *et al*., 2010 (PFS of 24 mos, approx. 18 mos *post* CIT). Hence, thresholds of 24 or 36 mos *after* CIT appear to be not properly validated. Also, large meta-analysis of 1558 pts by Cramer *et al.* 2015 didn't find statistically significant difference in OS at 1, 2 or 3 year thresholds and French Group results are based on relatively small (n =132) retrospective cohort. Additionally, although all cited studies analyzed prognostic role of early relapses solely after 1st line CIT, none of the guidelines mentioned the fact that suggested thresholds can't be extrapolated to relapses after further lines of therapy.

Table 1.

Table 1. Thresholds of "early relapse" after CIT in different recommendations.

Source	Cited studies*	Implied "early relapse" definition	Country	Year
IWCLL (Hallek et al., 2008)	-	No definition	Global	2008
NCCN guidelines 2.2018	-	No definition	USA	2018
EBMT CLL transplant consensus	MDACC, GCLLSG	≤ 24 mos post CIT	Europe	2007
SIE, SIES, GITMO	MDACC, GCLLSG	≤ 24 mos post CIT	Italy	2012
BCSH Guidelines	MDACC, GCLLSG	< 2 years post FCR/FC	UK	2012
East Midlands Cancer Network	-	< 2 years post FCR/FC	UK	2013
London Cancer CLL Guidelines	-	≤ 24 mos post FC	UK	2015
CancerCare Manitoba CLL Guidelines	MDACC	< 2 years post FCR	Canada	2015

Revised Dutch CLL Guidelines	MDACC	≤ 24-36 mos post FCR/BR	Netherlands	2018
Czech CLL Group	-	< 2-3 years post CIT	Czech Republic	2016
Swedish National Care Program	MDACC	< 2-3 years post CIT	Sweden	2016
BHS Guidelines	French, MDACC, GCLLSG	< 2-3 years post CIT	Belgium	2016
ESMO Guidelines	-	≤ 24-36 mos post CIT	Europe	2017
Danish Lymphoma Group	-	< 3 years post CIT	Denmark	2017
ARS Clinical Practice Guideline LYHE-007 v.4	MDACC	< 3 years post FCR, < 2-3 years post BR	Canada	2017

* MDACC – MD Anderson Cancer Center, GCLLSG – German CLL Study Group, French CLL Group

Summary/Conclusion: There is a considerable variability and paucity of evidence base in the thresholds for "early relapse" proposed by current CLL guidelines. This can potentially impede clinical practice, leading to untimely or/and unjustified therapeutic decisions when switch to newer inhibitors

and allogeneic stem cell transplantation is considered. Also, a question remains on which duration of remission can sufficiently predict sensitivity to CIT in the context of subsequent relapses. Analysis of large prospective datasets is needed.

PB1864

IL-2, IL-6, IL-17 AND IL-33 IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA COMPLICATED BY AUTOIMMUNE CYTOPENIAS

O. Vyhovska*, O. Danysh, K. Susida, K. Kotlyarchuk, O. Tsyapka, L. Lukavetskyy, Y. Vyhovska, Z. Maslyak

SI "Institute of Blood Pathology and Transfusion Medicine, NAMS of Ukraine", Lviv, Ukraine

Background: One of the important issues that should be considered within the studies concerning pathogenesis of the immune cytopenia in chronic lymphocytic leukemia (CLL) is impairment of the cytokine balance resulting from the disorders of the intercellular interactions between cytokine producing blood cells.
Aims: of the study were to investigate the level of certain regulatory cytokines in patients with CLL, including those with development of autoimmune hemolytic anemia (AIHA) and immune thrombocytopenia (ITP), which frequently may complicate the course of leukemia.
Methods: 68 CLL patients aged 45-77 years, including 39 without immune complications and 29 with presence of immune cytopenia not related to previous therapy were investigated. The male to female ratio was 1.3:1, the distribution by Rai stage was as follows: stage II-15 patients, stage III-31 patients, stage IV-13 patients. The control group consisted of 12 healthy subjects aged 50-80 years. The concentration of IL-2, IL-6, IL-17A and IL-33 was measured using the validated commercial ELISA kits.
Results: 39 patients with CLL without autoimmune complications appeared to have significantly increased IL-2 and IL-6 levels compared to healthy individuals, while IL-17A and IL-33 concentrations did not significantly differ from the control group (Tab.1). Positive DAT, elevated serum indirect bilirubin (55,27±18,6 umol/l), reticulocytosis (4,7±1,0%), and erythroid hyperplasia in bone marrow have been confirmed in 15 patients with CLL AIHA. There is a significant increase of IL-2, IL-6 and IL-17A levels compared to the healthy individuals in this group of patients (Tab.1). The concentration of IL-33 was 3 times higher than in the healthy individuals, but the difference was unreliable due to significant fluctuations of the results in some patients (Tab.1). In 14 patients with CLL mean platelet count was $37,6\pm10,7*10^9$/l, ITP was established on the basis of rapid blood thrombocytopenia and hypermegakaryocytosis in the bone marrow. Just like in patients from the previous two groups, their IL-2 and IL-6 levels were also significantly higher than those in healthy subjects. The concentration of IL-17A did not differ significantly from the control group and patients without immune complications, but was significantly lower than in subjects with AIHA. The level of IL-33 in this group was not significantly different from healthy individuals and patients from other groups (Tab.1).

Table 1.

Table 1. IL-2, IL-6, IL-17A, IL-33 in CLL patients without immune cytopenia, with AIHA and with ITP

Patients	IL-2 (pg/ml)	IL-6 (pg/ml)	IL-17A (pg/ml)	IL-33 (pg/ml)
Healthy individuals	8,12 ± 2,59	0,30 ± 0,17	10,02 ± 1,80	2,20 ± 0,50
CLL without AIHA or ITP	18,07 ±1,55*	2,89 ± 0,46*	14,28 ±1,86	1,77 ± 0,26
CLL with AIHA	16,35 ± 2,20*	6,86 ± 0,20*	16,88 ± 0,65*	3,71 ± 1,90
CLL with ITP	15,76 ± 2,04*	2,80 ± 0,59*	10,80 ± 1,87**	1,11 ± 0,29

*significant as compared to the healthy individuals
**significant as compared to the CLL with AIHA group

Summary/Conclusion: The obtained results reflect activation of the IL-17 production in patients with CLL-associated AIHA. Similar but not statistically significant changes were found also for IL-33, elevation of which was also reported in certain publications for cases of AIHA without leukemic background. However, in patients with CLL ITP levels of these cytokines were lower as compared to CLL AIHA, and did not significantly differ from the healthy individuals and CLL patients without immune cytopenia. This could possibly be a result of difficulties in differentiation between metaplastic and immune thrombocytopenia in CLL. At the same time significantly increased levels of IL-2 and IL-6 were observed in all three groups of patients which apparently reflects major impairments of the spectrum of regulatory cytokines in patients with advanced stages of CLL. Investigating the dynamic changes in concentration of these cytokines may be important for prognosis of the leukemia progression as well as development of CLL-associated AIHA.

PB1865

MITIGATION OF TUMOR LYSIS SYNDROME (TLS) COMPLICATIONS WITH VENETOCLAX (VEN) IN CLL

J.F. Seymour[1,2,*], M.S. Davids[3], A.W. Roberts[2], B. Eichhorst[4], T. Kipps[5], A. Mato[6], S. Stilgenbauer[7], M. Mobasher[8], M. Desai[9], G. Pena[9], J. Potluri[9], M. Verdugo[9], J. Nielsen[9], A. Cyr[9], L.L. Lash-Fleming[9], M. Hallek[4]

[1]Peter MacCallum Cancer Centre, and University of Melbourne, [2]Royal Melbourne Hospital, Melbourne, Australia, [3]Dana-Farber Cancer Institute, Harvard Medical School, Boston, United States, [4]Department of Internal Medicine, Center of Integrated Oncology Köln Bonn, and Cluster of Excellence on Cellular Stress Responses in Aging (CECAD), University of Cologne, Cologne, Germany, [5]University of San Diego, San Diego, [6]CLL Program, Leukemia Service, Division of Hematologic Oncology, Memorial Sloan Kettering Cancer Center, New York, United States, [7]Internal Medicine III, Ulm University, Ulm, Germany, [8]Genentech Inc., South San Francisco, [9]AbbVie, Inc., North Chicago, United States

Background: VEN can cause rapid tumor debulking in patients (pts) with relapsed/refractory CLL. Current VEN dosing schedule with TLS prophylaxis/monitoring averts overt TLS, but further data on emergent biochemical changes during VEN initiation are needed to guide practice.
Aims: To report on laboratory abnormalities observed during VEN initiation with 5-wk dose ramp up and current TLS prophylaxis/monitoring recommendations.
Methods: Pts were included from phase 2 trials of VEN for CLL with del(17p) (n=51) or prior BCRi therapy (n=117). VEN started at 20 mg QD with ramp up to 400 mg over 5 wk. Pts were categorized as low (L) TLS risk (nodes<5 cm and ALC<25), medium (M; node ≥5-<10 cm or ALC ≥25), or high (H; node ≥10 cm or ≥5 cm and ALC ≥25). Laboratory values, AEs, and relevant concomitant medications during ramp up were analyzed.
Results: TLS risk was categorized as 36% L, 36% M, and 27% H. 96% of pts completed ramp up; most in 5 wk. TLS AEs were reported in 4 pts (2 M; 2 H), with no clinical TLS and 1 laboratory TLS meeting Howard criteria (HC*). During VEN ramp up, 114 pts had potassium (K) >upper limit of normal (ULN) (1 K>HC); 21 were treated for rising or sustained K >ULN. 16 of these 21 had pre-VEN initiation K>ULN. 5/21 pts interrupted VEN for 1 day and all restarted VEN. 119 pts had phosphate (P) >ULN. 20 pts received P binder for P>HC during VEN ramp up and all others resolved without additional medication. Most instances were isolated; 4 pts had concurrent calcium (Ca^{2+}) or uric acid (UA) changes, and P was not treated in these cases. 70% of pts received allopurinol and 20% allopurinol and rasburicase at VEN start. 6 pts received rasburicase in addition to ongoing prophylaxis. Though 144 pts had Ca^{2+}<lower limit of normal (LLN), only 6 were treated.

Table 1.

n of pts		TLS risk L n=61	TLS risk M n=61	TLS risk H n=46	All N=168
K	>ULN	41	40	33	114
	>6 mmol/L*	0	1	0	1
	Treated	4	10	7	21
P	>ULN	34	44	41	119
	>1.5 mmol/L*	18	27	34	79
	Treated	1	8	11	20
Ca^{2+}		45	58	41	144
	<0.3 µmol/L*	0	4	4	8
	Treated	0	3	3	6
UA	>ULN	3	4	6	13
	>476 µmol/L*	2	2	4	8
	Treated	2	1	3	6

**Howard criteria (Howard et al., N Engl J Med 2011).*

Summary/Conclusion: Despite the frequency of K >ULN, treatment was applied in 13% of pts for rising or sustained elevation, and most had pre-VEN K >ULN. Most cases of P >ULN were isolated, asymptomatic, and resolved without intervention. VEN causes rapid tumor cytoreduction consistent with analyte changes, though clinical sequelae are rare and mitigated by approved dose ramp up, TLS prophylaxis/monitoring, and timely intervention.

DYNAMIC CHANGES IN HLA-DR EXPRESSION DURING SHORT-TERM AND LONG-TERM IBRUTINIB TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

G. Gabcova[1], Z. Mikulkova[1], G. Manukyan[2], T. Papajik[3], P. Turcsayni[3,*], R. Fillerova[1], T. Dyskova[1], V. Smotkova Kraiczova[1], S. Zehnalova[4], P. Gajdos[4], R. Urbanova[3], M. Kudelka[4], E. Kriegova[1]

[1]Department of Immunology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic, [2]Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia, [3]Department of Hemato-Oncology, aculty of Medicine and Dentistry, Palacky University and University Hospital,, Olomouc, [4]Department of Computer Science, Faculty of Electrical Engineering and Computer Science VSB-Technical University of Ostrava, Ostrava, Czech Republic

Background: There is the first evidence of different BCR internalization kinetics of neoplastic cells from the patients with chronic lymphocytic leukemia (CLL) after short-term and long-term administration with ibrutinib.
Aims: We aimed to assess the influence of short-term and long-term ibrutinib treatment on the HLA-DR expression on CLL and T cells.
Methods: The immunophenotyping of CLL and immune cells in peripheral blood was performed in 16 high-risk CLL patients treated with ibrutinib using a flow cytometry.
Results: Ur data demonstrated the reduced expression of HLA-DR on CLL cells early after ibrutinib administration (P=0.038) accompanied by an increase in CLL cell counts (P=0.003). *In vivo* reduction in the HLA-DR expression was confirmed by *in vitro* culturing of CLL cells with ibrutinib at protein and mRNA levels (P<0.01). The decrease in HLA-DR on CLL cells after the first month of the treatment was followed by the gradual increase of its expression by the 12$^{th\ month}$ (P=0.016) returning to the levels before initiation of the treatment. The one-month follow-up resulted in elevated absolute counts of CD4+ (P=0.003) and CD8+ (P<0.001) cells which were associated with the increased number of CD4+ and CD8+ cells bearing HLA-DR marker (P<0.001). The long-term administration was associated with increased numbers of CD4+ bearing HLA-DR (P=0.047), along with no changes in CD8+ bearing HLA-DR, CD4+ and CD8+ cell counts, respectively.
Summary/Conclusion: Our results provide the first evidence of the time-dependent immunomodulatory effect of ibrutinib on CLL and T cells. The clinical consequences of time-dependent changes in HLA-DR expression in ibrutinib treated patients deserve further investigation.

PB1867

SECOND LINE TREATMENT OUTCOMES IN CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN CLINICAL PRACTICE: RESULTS FROM A DECADE OF PRACTICE IN HELSINKI 2005-2015

V. Lindström[1], J. Mehtälä[2], R. Klement[3], A. Leval[4], T.M. Järvinen[5,*]

[1]Department of Hematology, Helsinki University Hospital Comprehensive Cancer Center and University of Helsinki, Helsinki, [2]EPID Research, Espoo, Finland, [3]StatFinn EPID Research, Tartu, Estonia, [4]Janssen-Cilag Ab, Solna, Sweden, [5]Janssen-Cilag Oy, Espoo, Finland

Background: Approximately 1800 individuals live with chronic lymphocytic leukemia (CLL) in Finland, with 350 diagnosed annually. Real-world treatment outcomes for this patient (pt) group have not been assessed previously in Finland and in the absence of direct head-to-head trials, robust historical control data have become important to ascertain the efficacy of novel therapies prior to introduction. The Finnish Hematology Registry (FHR) was created to allow for the collection of real-world practice outcomes in CLL and other hematological malignancies, with Finland's centralized nationwide healthcare system enabling reliable pt identification and comprehensive follow-up.
Aims: The aim of this registry study is to describe treatment and survival outcomes for CLL pts from routine practice settings, with special emphasis on second line treatment.
Methods: A non-interventional, retrospective study design was used to collect routine clinical practice data from the FHR. Eligible pts aged ≥18 years diagnosed with CLL and receiving 1 or more treatment lines during 2005-2015 were identified. As the registry had limited CLL pt follow-up data at study start, clinical investigators accessed medical records to retrieve and validate data. We report on 124 pts who met inclusion criteria from the Helsinki University Hospital, Helsinki, Finland, a hospital region accounting for 30% of the total national CLL incidence. Second line pts (n=64) were further stratified into those starting their treatment in 2006-2010 and in 2011-2015 time period, and treatment outcomes are described per time period and select treatments. For this initial analysis of 2nd line outcomes, crude overall survival (OS) and time-to-next-treatment (TTNT) were calculated per treatment line using Kaplan–Meier methods, with log-rank to estimate p-values.
Results: Median time to second line treatment was 31 months (m). During the follow-up, subtle changes in overall treatment practice were observed with fludarabine-cyclophosphamide-rituximab (FCR) and bendamustine-rituximab (BR) becoming the mainstay over fludarabine-cyclophosphamide (FC) after 2008. Across second line treatments, B/BR (36%), FCR (17%), chlorambucil-based therapies (20%) and (FC) (8%) were the most frequently used treatments. Novel agents ibrutinib, idelalisib+rituximab and obinutuzumab were not used prior to 2015. Median OS and TTNT from the start of any given 2nd line treatment were 37 m and 19 m, respectively. Pts receiving B/BR had shorter, though non-significant, median OS (37 m) compared to FCR (39 m) (p=0,51) (Table 1). TTNT was longer for pts receiving FC (33 m, p=0,42) and FCR (28 m, p=0,80) compared to B/BR (22 m). Despite apparent changes in treatment practice and increased use of chemoimmunotherapy over the years, improvements in 2nd line median OS (30 *vs* 42 m, p=0,19) and TTNT (10 *vs* 20, p=0,43) for the period 2006-2010 *vs* 2011-2015 did not reach statistical significance.

Table 1.

Table 1. Median second line overall survival (OS) and time to next treatment (TTNT) by select treatment regimens and treatment start time periods. NA; not reached.

	Treatment regimen (n)			Treatment start time period (n)	
	FC (5)	FCR (11)	B/BR (23)	2006-2010 (22)	2011-2015 (42)
Median OS (m), (95 % CI)	NA (36 – NA)	39 (36 – NA)	37 (22 – NA)	30 (18 – 47)	42 (26 – NA)
P-values	FC vs. BR = 0,14 FCR vs. BR = 0,51			0,19	
Median TTNT (m), (95 % CI)	33 (27 – NA)	28 (10 – NA)	22 (10 – NA)	10 (5 – 34)	20 (14 – 35)
P-values	FC vs. BR = 0,42 FCR vs. BR = 0,80			0,43	

Summary/Conclusion: We describe real-world CLL treatment trends and outcomes from a decade of practice in the Helsinki hospital region focusing on 2nd line regimens. These results are consistent with reports from Sweden (Asklid *et al.* 2016). Changes in treatment practice were observed between different time periods, however, results do not show significant improvements for OS and TTNT during this decade of follow-up. In the Nordics, real world evidence has become essential when introducing novel targeted therapies into clinical practice settings, with comprehensive disease registries expanding to allow for more detailed follow-up.

MULTICENTRIC REAL LIFE COHORT OF UNSELECTED CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS (CLL): MOLECULAR ANALYSIS, CLINICAL INTEGRATION AND PROGNOSTIC IMPLICATIONS

R. Murru[1,*], S. Uda[1], G. Piras[2], S. Oppi[1], R. Asproni[2], F. Culurgioni[1], M. Monne[2], A. Uras[2], A. Bianchi[2], A.D. Palmas[2], G. Latte[2], G. La Nasa[1]

[1]SC Ematologia E Ctmo, Ospedale Oncologico A. Businco Ao Brotzu, Cagliari, [2]uoc Ematologia, Ospedale San Francesco Assl Nuoro-Ats, Nuoro, Italy

Background: Clinical heterogeneity of chronic lymphocytic leukemia (CLL) ranges from an indolent course to a very aggressive disease, while some patients never need treatment whilst many others require multiple lines of therapy during their lifetime and often die from disease. Integration between biological and clinical findings, with particular reference to innovative prognostic markers, is an increasingly pressing need for a risk stratification tool, useful for predicting disease outcome. Translation on real life setting and into everyday care is a real proposal in helping physicians to make better decisions.
Aims: To determine and analyze the most relevant biological and clinical characteristics of a multicentric real life CLL cohort and their impact on overall survival (OS) and time to progression (TTP), comparing with those reported in the literature.
Methods: A multicentric real life cohort of 273 unselected CLL patients in different clinical Binet stage were retrospectively analyzed for IGHV status, CD38 expression, *NOTCH1* mutation (mut), FISH (*del13q, tris12, del11q, del17p*), *TP53* mutational status. A large part of patients (n°190, 70%), have been included in a clinical research project currently in progress, apply-

ing ultra-deep Next Generation Sequencing (NGS), with a major aim to point out new possible prognostic or predictive biological markers (data in progress). All patient, 114 untreated (42%) and 159 treated patients (58%), have been diagnosed from 01/1988 to 01/2018, with a long term follow up (median: 89.2 months; range: 2-343). Biological and clinical patient characteristics are summarized in table 1. All data have been statistically analyzed using Prism 4.

Results: We investigated OS in patients with stage A (107.7 months), stage B (75.5 months) and C (70.1 months), defined at diagnosis ($p<0.001$). Median time to progression (TTP) was 52 months for all treated patients, regardless of Binet stage at diagnosis. Moreover, IGHV mutational status was analyzed at diagnosis in 171 (63%) patients (unmutated: 22%; mutated: 78%), reporting statistically significant differences in median OS, regardless of treatment (95.3 months and 89.2 months, respectively; $p<0.001$). CD38 expression was evaluated in 191 patients (70%), analyzed and integrated with FISH aberrations and IGHV status. FISH analysis was overall performed in 238 samples (before first line therapy: n°200; relapsed/refractory: n° 38), identifying a small group (7%) with multiple aberrations and unfavorable prognosis. *NOTCH1* c.7544_7545delCT mutations were investigated in 207 DNA samples (76%). *NOTCH1*-mut was detected in 23 patients (11%) and correlated with *tris12* and IGVH status, analyzing impact on overall survival (OS). Only 9% of NOTCH1 mut developed Richter syndrome with fatal outcome, confirming a worse prognostic role characterized by chemoresistance and rapid disease kinetics.

Table 1.

BIOLOGICAL AND CLINICAL CHARACTERISTICS OF PATIENTS			
	N° of patients	%	Median (OS in months)
Cohort of unselected patients	273		89.2
Binet stage A	156/227	69	107.7
Binet stage B	49/227	21	75.5
Binet stage C	22/227	10	70.1
Females	112	41	
Males	161	59	
Median age at diagnosis			64 yrs (36-90)
IGHV mutated status	134/171	78	89.2
IGHV unmutated status	37/171	22	95.3
CD38 expression	191/273	70	
CD38+	44/191	23	
CD38+/IGHV mut	27	61.3	
CD38+/IGHV unmut	11	25	
CD38+/ IGHV not evaluated	6	13.7	
CD38+/negative FISH	13	29.5	
CD38+/del13q	8	18.3	
CD38+/tris12	7	15.9	
CD38+/del11q	2	4.5	
CD38+/TP53 mutation	1	2.3	
CD38+/FISH not evaluated	13	29.5	
NOTCH1 mutated status	25/207	12	
FISH	238	87.2	
del13q	76	32	88.6
Tris12	35	15	85.37
del11q	13	6	75.3
del17p/TP53 mutation	8	3	80.9
Complex caryotipe (del 13q/del11q, del 13q/del17q, del13q/TP53mutation)	17	7	70.8
TP53 mutation	5	2	55.4
FISH negative	84	35	82.3

Summary/Conclusion: We choose to emphasize our real life data related to IGHV, FISH aberrations and *NOTCH1 mut*, not yet widely applied in everyday care, confirming the need for early identification of well-known biological and clinical findings. Interesting results related to IGHV and OS must be validated through large prospective cohort study, suggesting a clue for possible other biological factors and encouraging the introduction of innovative genetic lesion analysis (ie, NGS), with the aim of selecting high risk *vs* low risk patients.

PB1869

HIGH DOSE METHYLPREDNISOLONE AND RITUXIMAB IN RELAPSED PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

R. Pileckyte[1,2,*], V. Valceckiene[2], J. Sejoniene[3], L. Griskevicius[1,2]

[1]Clinics of Internal, Family Medicine and Oncology, Faculty of Medicine, Vilnius University, [2]Hematology, Oncology and Transfusion Medicine Center, [3]Radiology Center, Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania

Background: BTK and BCL2 inhibitors have changed the treatment paradigms of high risk and/or elderly patients with chronic lymphocytic leukemia (CLL), but long term efficacy and toxicity are still unknown and the costs are relevant. Rituximab (RTX) and high dose methylprednisolone (HDMP) can be an effective and safe treatment option for relapsed CLL. Here, we present the long term results of two phase II studies of HDMP and RTX combination given in different schedules.

Aims: LT-CLL-001: to evaluate the efficacy and safety of HDMP and RTX in relapsed (R) high risk CLL patients.LT-CLL-2S: to evaluate the efficacy and safety of HDMP and RTX in relapsed elderly or unfit CLL patients

Methods: In LT-CLL-001 R CLL patients with high risk features (17p del, *TP53* mut, 11q del and/or trisomy 12 or fludarabine refractory) were included. The treatment schedule was described elswere.[1]In LT-CLL-2S study, relapsed patients with CIRS >6 and / or ≥65 years were included. HDMP was administered at 1 g/m^2 iv daily for 3 days of each course for 4 or 6 courses. RTX was administered at 1000 mg/m^2 on day 1 of each course for 4 courses. Treatment cycles were repeated every 3 weeks.

Results: 29 patients were enrolled in LT-CLL-001. Demographic data have been described elswere[1]. The median observation time was 31 (1-76) month. The follow up for alive patients was 66.5 (60-76) months. Overall response rate (ORR) was 62%, all partial remissions (PR). The median progression free survival (PFS) and overall survival (OS) were 12 and 31 months. Five-year OS was 21% for all the patients; for patients with 17p deletion/*TP53* mutation 3-year OS was 38%, 5-year OS was 8%. Grade III-V infections were observed in 2% of all AEs.3 patients died during treatment phase. There were 3 cases (10.3%) of secondary malignancies: 1 Richter transformation, 1 polycythaemia vera and 1 breast cancer.25 patients were included in LT-CLL-2S. The median age was 73 years (range 65-80), 6 (26%) had 17pdel/*TP53* mutation, 3 (12%) had 11q del. 9 patients were given >4 courses 16 patients were given ≤4 courses. ORR was 28%, all PR, mainly due to residual lymphadenopathy. All 18 patients with B symptoms had their symptoms resolved. Significant improvement in anemia *($p<0,001$)* was noted. The median follow-up was 44 (11-69) months. The median PFS was 11 months (range 10-12). Median OS was 68 (62-74) months. No difference in ORR or PFS was noted between patients who received ≤4 or >4 courses, but a tendency for better OS was observed for the patients with more treatment (36 months *versus* not reached, *$p=0.062$*). AE were mainly I-II° (82%), no deaths occurred during treatment.After their respective study, the relapsed patients with treatment indications recieved ibrutinib in notable difference between the studies: one (5%) out of 20 LT-CLL-001 patients compared to 7 (32%) out of 22 LT-CLL-2S patients.

Summary/Conclusion: Lower ORR was observed in LT-CLL-2S compared to LT-CLL-001 mostly because of residual lymphadenopathy. However, median PFS between the studies were similar and toxicity of LT-CLL-2S was lower.The different ORR in two studies could be explained by the higher dose of HDMP in LT-CLL-001. The longer median OS in LT-CLL-2S could be explained by lower number of high risk patients and the availability for BTK inhibitors as salvage therapy. HDMP and RTX combination can still be applied in some relapsed high risk and elderly or unfit CLL patients without the significant risk of concomitant diseases exacerbation if new therapies are contraindicated or unavailable.

PB1870

THE VALUE OF RITUXIMAB-CONTAINING CHEMOTHERAPY IN SECOND-LINE WITH OR WITHOUT PREVIOUS RITUXIMAB EXPOSURE: A POPULATION-BASED STUDY AMONG PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA IN THE NETHERLANDS

L. van der Straten[1,2,*], M.-D. Levin[2], E. van den Broek[3], O. Visser[4], W. Posthuma[5,6], J. Doorduijn[7], A. Kater[8], A. Dinmohamed[1,7,9]

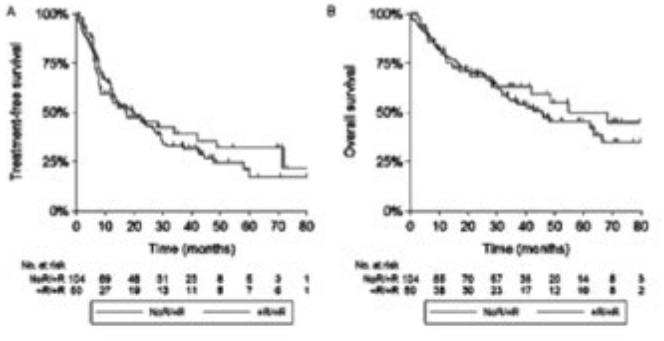
[1]Research, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [2]Internal Medicine, Albert Schweitzer Hospital, Dordrecht, [3]PALGA Foundation, Houten, [4]Registration, Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht, [5]Internal Medicine, Reinier de Graaf Group, Delft, [6]Hematology, Leiden University Medical Center, Leiden, [7]Hematology, Erasmus MC Cancer Institute, Rotterdam, [8]Hematology, Academic Medical Center, Amsterdam, [9]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands

Background: In an era with novel agents, chemoimmunotherapy with rituximab (R) still generally constitutes the cornerstone of first-line chronic lymphocytic leukemia (CLL) treatment. International clinical practice guidelines recommend to repeat first-line chemoimmunotherapy if the treatment-free interval between first- and second-line treatment is over 24 to 36 months. However, the effectiveness of R-based regimens in second-line—with or without previous R-based regimens in first-line—has virtually not been evaluated at the population level.

Aims: The aim of this population-based study was to assess the effectiveness of R-based chemotherapy for the second-line treatment of CLL patients in relation with first-line treatment with or without R-based chemotherapy.

Methods: We selected all CLL patients diagnosed between 2004-2008 who initiated second-line treatment with R-containing chemotherapy from the PHAROS CLL registry that encompasses ~40% of the Dutch population and is notified by the nationwide Netherlands Cancer Registry. Patients who initiated second-line treatment with R-based chemotherapy were categorized into two groups, namely those who received first-line chemotherapy with (+R/+R) or without R (NoR/+R). The primary and secondary endpoint was treatment-free survival (TFS) and overall survival (OS), respectively (see definitions in Fig 1). Multivariable Cox regression was used to assess covariates (listed in Table 1) associated with TFS and OS. A $P<0.05$ indicates statistical significance.

Results: A total of 154 rituximab-treated CLL patients were included in this analysis, of whom 104 (68%) and 50 (32%) were in the NoR/+R and +R/+R group, respectively. Patients in the NoR/+R group were significantly older than patients in the +R/+R group (median age 71 [range 37-88] *vs* 67 [range 40-83] years; $P=0.046$). Most patients in the NoR/+R and +R/+R group received first-line treatment with alkylating agents (86% *vs* 84%; $P=0.797$), followed by purine analogues (PA; 13% *vs* 14%; $P=0.795$). In the second-line setting, 54% and 20% of patients received R with alkylating agents, 22% and 28% with PA, and 24% and 53% with other modalities (*i.e.* R monotherapy or DHAP) in the NoR/+R and +R/+R group, respectively ($P<0.001$). At a median follow-up of 30.7 months (range 0.2-115), the median TFS was 19.6 (95% confidence interval [CI], 12.6-27.3) and 17.1 months (95%CI, 7.9-48.6) for the NoR/+R and +R/+R group, respectively ($P=0.627$). Third-line treatment was started in 48% and 36% and deaths occurred in 51% and 42% in the NoR/+R and +R/+R groups, respectively. The median OS was 45.8 (95% CI, 31.9-66.5) and 54.9 months (95% CI, 27.7-not reached) for the NoR/+R and +R/+R group, respectively ($P=0.433$). In multivariable analysis, first-line treatment with R±PA, as compared with R±alkylating agents, was associated with lower TFS ($P=0.009$) lower OS ($P=0.003$). In addition, second-line treatment with R-based regimens without alkylating agents or PA ($P=0.049$), as compared with R with PA, and time between first- and second-line treatment per one month increase ($P=0.023$) was associated with better TFS. Furthermore, age per one increase was associated with lower OS ($P=0.004$).



- Treatment-free survival was defined as the time for start of second-line treatment until institution of third line treatment or death resulting from any cause, or last follow-up (December 31, 2014), whichever occurred first.
- Overall survival was defined as the time for start of second-line treatment until death resulting from any cause or until the last date the patient was known to be alive (December 31, 2014), whichever occurred first.

Table 1. Multivariable Cox regression for treatment-free survival and overall survival

Covariate	Treatment-free survival				Overall survival

Figure 1.

Summary/Conclusion: In this population-based study, we demonstrated that TFS and OS among rituximab-treated CLL patients in second-line was not influenced by first-line chemotherapy with R. This novel finding illustrates that R-based chemotherapy in second-line is a viable treatment option among particular patient subsets in an era with novel, expensive agents.

Background: Chronic lymphocytic leukemia (CLL) patients are at a significantly increased risk of developing a second malignant neoplasm. Recent introduction of B-cell receptor inhibitors (BCRi) ibrutinib and idelalisib was a major breakthrough in the treatment of relapsed and refractory disease. However, knowledge on incidence of second cancers in the context of BCRi therapy is limited.

Aims: To study the incidence and pattern of second cancers and Richter transformation (RT) in relapsed and refractory CLL patients treated with ibrutinib or idelalisib.

Methods: Retrospective analysis was performed concerning diagnosis and outcome of second malignancies occurring during BCRi treatment in Polish hematology centers of the Polish Adult Leukemia Study Group (PALG).

Results: Clinical data of 211 heavily pretreated relapsed and refractory CLL patients, of whom 157 received ibrutinib and 54 were treated with idelalisib, were included in the analysis. Median ibrutinib treatment duration was 33.5 (range 0.4-46.8) months. Eleven (7%) second malignancies developed under ibrutinib therapy including 7 cancers of epithelial origin (2 lung cancers, 2 skin cancers, 1 peritoneal cancer, 1 urinary bladder and 1 breast cancer) and 4 cases of RT (3 histologically confirmed Hodgkin variant of RT and 1 clinically suspected RT of unknown histology). Median time from CLL diagnosis to the diagnosis of second malignancy was 83.1 (38.3-298.0) months, while median time from ibrutinib initiation to second cancer reached 19.63 (3.9-31.9) months. Idelalisib alone or in combination with anti-CD20 antibodies was administered for a median of 13.8 (0.1-23.5) months. In the group of idelalisib treated patients 7 (12.9%) malignancies occurred including 5 epithelial cancers (2 thyroid cancers, 1 renal cancer, 1 penile cancer and 1 gastric cancer) and 2 RT. Median time from CLL diagnosis to second cancer and median time from idelalisib start to diagnosis of second cancer were 47.7 (13.1-178) months and 21.3 (2.3-31.5) months, respectively. Comparing the frequency of second malignancies in ibrutinib and idelalisib treated patients, we did not reveal significant differences between both cohorts (p=0.25). The analysis of clinical decisions following the diagnosis of second malignancies in this real-life patient population showed different strategies including transient or permanent discontinuation of BCRi or dose modifications. Regarding the outcome of patients with second cancer, 6 out of 11 patients in the ibrutinib cohort and 2 out of 5 patients treated with idelalisib died. Importantly, in all these cases the second malignancy was the primary cause of death.

Summary/Conclusion: In this retrospective analysis we show that second cancers are not an uncommon clinical problem during BCRi therapy of

CLL, at least in relapsed refractory patients, heavily pretreated with standard alkylating agents and/or purine nucleoside analogs based therapies. Interestingly, we observed more epithelial cancers than RT. The potential influence of specific type of BCRi on incidence of second cancers as well as optimal dosing of BCRi during systemic treatment of second malignancies needs further research.

PB1872

INFLUENCE OF INTENSITY CHEMOTHERAPY ON THE FREQUENCY OF MRD NEGATIVE REMISSIONS IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

M. Mikhaleva[1,*], A. Kuvshinov[1], S. Voloshin[1], E. Belyakova[2], E. Krasnikov[3]

[1]Clinical Department of Chemotherapy of Hemoblastosis, Depression of Hemopoiesis and Bone Marrow Transplantation, Federal State Budget Institution "Russian Scientific and Research Institute of Hematology and Transfusiology of Federal Medical Biological Agency", [2]North-western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russian Federation, [3]St. Petersburg State Budgetary Healthcare Institution City Hospital №40, Saint-Petersburg, Russian Federation, Saint-Petersburg, Russian Federation

Background: Minimal residual disease (MRD) is a powerful prognostic factor in the course of chronic lymphocytic leukemia (CLL). The achievement of MRD negative (MRD^{neg}) remissions is associated with a longer survival of patients with CLL. In addition, it is known that increasing of intensity the induction chemotherapy regimens allows to achieve the maximum eradication of the tumor clone and, thereby, to increase the duration of progression free survival (PFS).
Aims: To assess influence of intensity the induction chemotherapy on the frequency of achievement MRD^{neg} status and duration of PFS.
Methods: In this study were included 118 patients with CLL (male/female ratio 1.3:1), age 31 to 80 years (median 61 years). The median of follow-up duration is 36 months (range 5-84). We have used the revised NCI guidelines (Hallek M, *et al*., 2008) for diagnosis, initiation of therapy, evaluation of response and MRD (10^{-4}). Patients were treated with rituximab-containing chemotherapy regimens (RFC, RB, RChl, R-CHOP). Median of chemotherapy lines-1 (range 1-3). Patients were divided into three groups depending on the number of cycles of chemotherapy: group 1-4 cycles (n=18), group 2-6 cycles (n=78), group 3-8 cycles (n=22). The evaluation of MRD status was carried out using 5-color flow cytometry on bone marrow samples after 2 months of completion chemotherapy. In addition, intermediate evaluation of MRD status after 4 treatment cycles was carried out in group 2 (n=36) and group 3 (n=6) underwent.

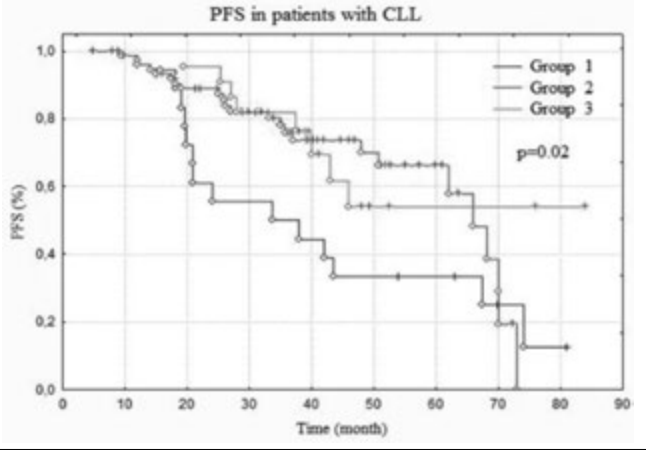

Figure 1.

Results: Group 1: complete remission (CR)-4 (MRD^{neg}-2), partial remission (PR)-14 (MRD^{neg}– 2); group 2: CR-16 (MRD^{neg}-6), PR-62 (MRD^{neg}-26); group 3: CR-6 (all MRD^{neg}), PR-16 (none MRD^{neg}). The frequency of achievement of MRD^{neg} status at the completion of chemotherapy regimen was: group 1-22.2% (4/18), group 2-41.0% (32/78), group 3-27.3% (6/22) (p>0.05). The frequency of achievement of MRD^{neg} status after 4 cycles of chemotherapy in group 2-22.2% (8/36) and in group 3-33.3% (2/6). Median PFS in group 1 was 33.7 months, in group 2-66.0 months, and in group 3-not achieved (p=0.02). When comparing PFS in patients among all groups who achieved MRD^{neg} status after 4 cycles of chemotherapy no significant differences were found, which is probably due to a small number of events and short observation period. However, it was noted that progression/relapse of the disease was occurred only in the group 1-11.1% (2/18), while in groups 2 and 3, progression/relapse of the disease was not detected in any patient who achieved MRD^{neg} status after 4 cycles of treatment (p=0.016).
Summary/Conclusion: Consider that intensity of chemotherapy does not affect on the frequency of achievement MRD^{neg} status, but affects on PFS, we can assume that patients with a large number of cycles of chemotherapy achieved a deeper MRD^{neg} status (less than 10^{-4}). Intensification of chemotherapy regimens can increase the risk of significant hematologic toxicity and infectious complications, that requires a personified management strategy for patients with CLL.

PB1873

ADVANCED DATA-MINING METHODS REVEALED FOUR SUBGROUPS AMONG HIGH-RISK CLL PATIENTS

P. Turcsanyi[1,*], M. Kudelka[2], M. Radvansky[2], E. Kriegova[3], L. Kruzova[1], R. Urbanova[1], P. Schneiderova[3], H. Urbankova[1], T. Papajik[1]

[1]Hemato-Oncology, Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic, Olomouc, [2]Department of Computer Science, Faculty of Electrical Engineering and Computer Science, VSB-Technical University of Ostrava, Ostrava, [3]Department of Immunology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic, Olomouc, Czech Republic

Background: The clinical course of chronic lymphocytic leukemia (CLL), the most common leukemia in western countries, is highly heterogeneous. Further stratification of CLL patients who may profit from novel targeted therapies is critically needed, particularly in high-risk patients.
Aims: To subdivide the high-risk CLL patients based on the clinical course, overall survival (OS) and treatment response.
Methods: Study cohort consisted of 116 high-risk CLL patients (F/M 36/80, median age 63 yrs, min-max 34-87 yrs) diagnosed between 2000 to 2015 in single reference centre. Besides genetic aberrations (del(11q), del(17p), *TP53* mutation and complex karyotype, CK), age, gender, Binet stage, blood counts, beta-2-microglobulin, thymidinkinase, LDH, splenomegaly, bulky lymphadenopathy (>5 cm) at the time of diagnosis and clinical course, treatment response and OS were evaluated. Advanced data-mining methods were used to analyse the data.
Results: The network analysis revealed four subgroups of patients differing in their profiles of genetic aberrations, bulky lymphadenopathy, splenomegaly and gender. The best prognosis was observed for Profile (P)-I (n=47, predominantly men with del(11q) + no CK + no TP53 disruption) and P-II (n=29, men/women + del(11q) with CK + no TP53 disruption) with OS 70 and OS 54 mo, respectively. The ultra high-risk patients were those with P-III (n=19, predominantly women with del(17p)/*TP53* mutation) and P-IV (n=21, men/women with CK + TP53 disruption) with OS 38 and OS 40 mo, respectively. The OS differed between (P-I and P-II) and (P-III and P-IV) (p<0.002). Of 54 patients treated with fludarabin, 33% were refractory (10.6% P-I, 13.8% P-II, 31.0% P-III, 14.3% P-IV). Adding rituximab to therapy did not improve OS in our patients regardless of profiles (p=0.98). Patients who required treatment shortly after diagnosis (<3 mo) had the shortest OS (48 mo) *versus* those treated later, evident in all profiles (OS 84 mo, p=0.037).
Summary/Conclusion: Our data showed that patients within P-III (women with del(17p)/*TP53* mutation) and P-IV (men/women with CK and TP53 disruption) have the worst prognosis among high-risk patients. These ultra high-risk patients are candidates for novel upfront treatment algorithms.

PB1874

PROSPECTIVE REAL WORLD DATA OF AN ONGOING POST-AUTHORIZATION SAFETY STUDY ON IDELALISIB IN PATIENTS WITH CLL AND REFRACTORY FL

W. Knauf[1,*], M. Hoechstetter[2], P. Eissmann[3], N. Hucke[3], A. van Troostenburg[3], H. Ramroth[3], M. Rummel[4]

[1]Centrum Haematologie / Onkologie Bethanien, Frankfurt a. M., [2]Klinikum Schwabing, Munich, Germany, [3]Gilead Sciences Inc., Foster City, United States, [4]Universitätsklinikum Giessen, Giessen, Germany

Background: Idelalisib, a first-in-class PI3Kδ inhibitor, is indicated in combination with rituximab or ofatumumab for the treatment of adult patients with chronic lymphocytic leukemia (CLL) who have received at least one

prior therapy or as first-line treatment in the presence of 17p deletion or *TP53* mutation in patients who are not eligible for any other therapies and as monotherapy for the treatment of adult patients with follicular lymphoma (FL) that is refractory to two prior lines of treatment.
Aims: To prospectively collect safety and efficacy data on idelalisib use in routine clinical practice in Germany.
Methods: A prospective, two-cohort, multicenter, non-interventional post authorization safety study (PASS); inclusion of patients is based on the physician's decision to initiate treatment with idelalisib in accordance with the German Summary of Product Characteristics; primary objectives are progression-free survival, overall response rate and overall survival; secondary objectives include the incidence and severity of adverse drug reactions and fatal events; descriptive statistics are used for data analysis.
Results: The second pre-planned interim analysis includes results of 93 patients (83 patients with CLL, 10 patients with FL) in 49 active sites in Germany that had completed at least 3 months after initiation of idelalisib treatment. Patients with CLL had a median age of 74 years and were predominantly male (69%) while patients with FL had a median age of 66 years and were predominantly female (90%). Median time from diagnosis to start of idelalisib therapy was 93 (range 0.4-307.8) months for CLL and 37 (range 21.5-360.1) months for FL. 68% of patients had a Karnofsky index of ≥80 and 86% of patients presented with one or more co-morbidities. 35% (n=88) of documented co-morbidities (n=249) were diseases of the circulatory system according to ICD-10 classification. Among these the most frequently reported were hypertensive disease (n=41), cardiac arrhythmias (n=15) and chronic ischemic heart disease (n=10). In the CLL cohort deletion 17p and/or *TP53* mutation was detected in 21%, deletion 11q in 19% and deletion 13q in 23% of patients. The median observation time was 6 months for the entire study population, 7 months for the CLL and 5 months for the FL cohort. By the time of data extract 63% of patients had permanently discontinued idelalisib treatment with a median time to permanent treatment discontinuation of 5 months. A total of 75 treatment interruptions were reported.
Summary/Conclusion: Post-authorization safety and efficacy data are important to assess the benefit/risk profile of therapies in routine clinical practice. Our prospective PASS on the use of idelalisib in Germany is therefore reporting safety and efficacy data on an ongoing basis.

PB1875

MAINTENANCE DOSING OF IBRUTINIB FOR CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL) / SMALL LYMPHOCYTIC LYMPHOMA PATIENTS

W. Alexander, R. Ramakrishna*

Southern Haematology and Cancer Research Institute, Wollongong, Australia

Background: Ibrutinib is a BTK inhibitor, indicated for use in CLL/SLL patients as a second line therapy when purine analogues are either infective, or contraindicated. Standard dosing regime is 420 mg daily. Complications associated with this level of dosing include skin lesions or infections, cardiac arrhythmias, hypertension, bleeding, secondary malignancies and other infections. It has been suggested that reduced dosing may be equally efficacious in this patient group.
Aims: To consider the efficacy of reduced dose of ibrutinib (maintenance dosing) for retaining remission in CLL/SLL patients who have achieved CR or VGPR on full dose therapy.

Table 1.

Table 1.
Number of patients affected by complications of full dose ibrutinib therapy

Side Effects prior to dose reduction	Number affected
Skin lesion (acne-like)	3
Skin abscess and/or cellulitis	3
Nail changes	1
AF	2
Hypertension	1
Bruising and/or epistaxis	3

Methods: A retrospective data audit was conducted on all patients who had received maintenance dosing of ibrutinib at Southern Sydney Haematology. Criteria being assessed included total time on therapy, time on maintenance dosing, effects of reduced dosing on any side effects, evidence of relapse, and basic demographic data.
Results: Out of 40 patients treated with ibrutinib at the facility, a total of 13 patients had received reduced dosing with ibrutinib: 8 males and 5 females. Median age was 69 (range 63-77). Total time on therapy was a median of 35 months (range 31-36 months) while time on reduced dosing was a median of 14 months (range 6-24 months). Seven patients had developed various side effects on full dose therapy (table 1) but none of these side effects recurred on reduced dosing. One patient developed new onset atrial fibrillation seven months after starting reduced dosing of ibrutinib that is currently medication controlled. No patients have relapsed on reduced dosing and this entire cohort remains on maintenance therapy.
Summary/Conclusion: Based on findings from this cohort, reduced dosing of ibrutinib 980 mg -1260 mg/week for patients who have achieved VGPR or CR and have been stable on therapy for 12-24 months would appear to be sufficient to maintain remission and a good way for managing skin lesions or other minor side effects. This confirms the results of other small-scale studies conducted at other institutions.

PB1876

OBINUTUZUMAB IN FIRST-LINE TREATMENT OF ELDERLY/ COMORBID PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA- THE REAL-WORLD RESULTS OF POLISH ADULT LEUKEMIA GROUP (PALG)

M. Długosz-Danecka[1,*], W. Jurczak[1], E. Łątka[1], M. Morawska[2], K. Gawroński[3], A. Wiśniewska[4], M. Dudziński[5], E. Wąsik-Szczepanek[6], E. Chmielowska[7], A. Łabędź[8], K. Wdowiak[9], E. Paszkiewicz-Kozik[10], I. Hus[11]

[1]Department of Hematology, Jagiellonian University, Krakow, [2]Experimental Hematooncology Department, Medical University of Lublin, Lublin, [3]Department of Hematology, Military Institute of Medicine, Warszawa, [4]Department of Oncology and Chemotherapy, Kopernik Memorial Specialist District Hospital, Koszalin, [5]Department of Hematology, Clinical District Chopin Memorial Hospital, Rzeszów, [6]Department of Hematooncology and Bone Marrow Transplantation, Medical University of Lublin, Lublin, [7]Department of Clinical Oncology, Oncology Centre, Bydgoszcz, [8]Department of Hematology, Rydygier Memorial Hospital, Krakow, [9]Department of Internal Medicine and Oncology, Silesian Medical University, Katowice, [10]Department of Lymphoid Malignancies, Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, [11]Department of Clinical Transplantology, Medical University of Lublin, Lublin, Poland

Background: The current first-line treatment for fit chronic lymphocytic leukemia (CLL) patients remains fludarabine-based therapy. Elderly patients with numerous comorbidities, poorly tolerate such regimen and pose a huge challenge.
Aims: In our analysis, we investigated the efficacy and safety obinutuzumab-chlorambucil combination in elderly and unfit patients.

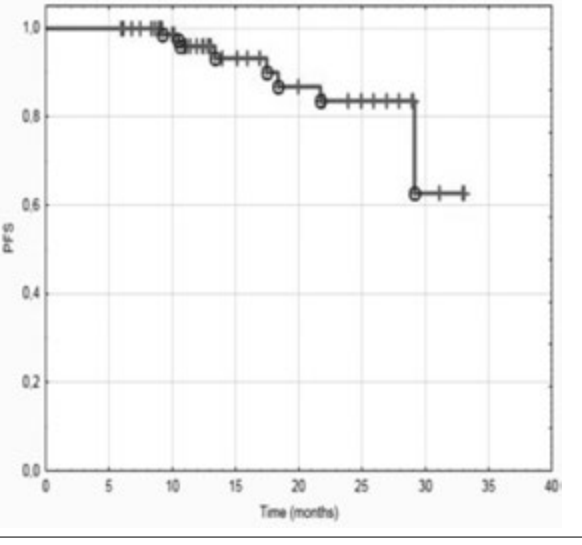

Figure 1.

Methods: We include in our analysis 86 treatment-naïve CLL patients (median age 74 years, range 51-86 years) with significant burden of coexisting comorbidities. All patients presented the Cumulative Illness Rating Scale (CIRS) score greater than 6 and/or creatinine clearance (CrCl) of 30–69 ml/min. Most patients (94,19%) had four or more coexisting comorbidities, with cardiovascular, endocrine or metabolic, respiratory and genitourinary disorders being the most frequent. Obinutuzumab was infused intravenously

at 1000 mg on days 1, 8 and 15 of cycle 1 and on day 1 of cycles 2–6 (28-day cycles) with first infusion split over 2 days for patients' safety. Chlorambucil was administered orally at a dose of 0.5 mg per kilogram of body weight on days 1 and 15 of each cycle.
Results: Overall response rate (ORR) at 2 months after treatment completion was 95.35% including complete remission (CR) in 37 patients (45.12%) and partial remission (PR) in 45 patients (54.88%). Stable disease was noted in 4 patients (4.65%) and progressive disease (PD) was not observed after the end of therapy. The median progression free survival (PFS) was 13,05 months. The relapses occurred in 6 patients (7%) with 3 patients (3.5%) completing treatment with CR and 3 (3.5%) with PR. The median number of treatment cycles was 6. The most frequent adverse events (AE) were infusion-related reactions (IRR) and neutropenia. Grade 3 IRR occurred in 2.3% of patients, grade 2 in 12.8% (in 81.8% of patients only during the first infusion of monoclonal antibody). Grade 3 neutropenia was reported in 11.6% of patients, grade 2 in 22.1% with no incidence of febrile neutropenia. There were no AE of grade 4 or 5.
Summary/Conclusion: Our data confirm that obinutuzumab-chlorambucil is an effective and well-tolerated regimen in untreated CLL patients with comorbidities.

PB1877

ATRIAL FIBRILLATION IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA RECEIVING TREATMENT WITH IBRUTHINIB

G. Gendlin*, E. Emelina, I. Nikitin

Hospital Therapy N 2, Pirogov Russian National Research Medical University, Moscow, Russian Federation

Background: Atrial fibrillation (AF) is a frequent comorbidity in patients with chronic lymphocytic leukemia (CLL) receiving treatment with ibrutinib (Ib).
Aims: To study the incidence of AF and the possibility of using various anticoagulants in patients with CLL in the background of treatment with Ib.
Methods: We examined 174 patients with CLL who received Ib 420 mg as the first, second, third and fourth lines of therapy. All patients underwent electrocardiography, echocardiography and 24-hour ECG monitoring.
Results: The study included patients aged 32 to 95 years (66.0 (59.0-72.0) years), 111 men aged 32 to 95 years (66.0 (60.0-72, 0) years) and 63 women aged 39 to 83 years (64.0 (54.0 -71.0) years), p=0.34. AF was detected in 25 patients (14.7%) receiving Ib. In 11 patients (6.4%) AF diagnosed before the onset of treatment with Ib. In 14 patients (8.2%) AF occurred during the treatment with Ib in the period from 1 to 24 months (4.5 (2.0-16.0) months). 6 patients with AF (24%) had a permanent form, 19 had paroxysmal AF (76%). In 2 patients the paroxysmal form changed to a constant one during the Ib treatment period. In accordance with the recommendations of the ESC on diagnosis and treatment of AF in 2016 and the scale CHA_2DS_2-VASc, anticoagulants received 14 patients (56%), of whom 3 patients received dabigatran etexilate (dabi) at a dose of 150 mg * 2 times a day, 7 patients received rivaroxaban (riva) at a dose of 20 mg per day, 4 patients was treated apixaban (api) at a dose of 5 mg * 2 times a day. In 3 patients (12%) receiving anticoagulants occurred non-major bleeding: in one patient taking riva 20 mg / day there was hematuria during occurred thrombocytopenia and anticoagulant treatment was canceled; one patient receiving dabi 150 * 2 times a day had repeated nasal bleeding (to him was prescribed api at a dose of 2.5 mg * 2 times a day); in one patient treating with api 5 mg * 2 times a day there was a hematoma with a small external bleeding (the dose was reduced to 2.5 mg * 2 times a day). Riva was abolished in 3 patients (12%) because of severe thrombocytopenia.
Summary/Conclusion: Careful monitoring of patients with CLL and AF receiving treatment with Ib and anticoagulant therapy is necessary to early detect thrombocytopenia, hemorrhagic complications and timely dose adjustment or anticoagulant withdrawal.

PB1878

THE NUMBER OF PREVIOUS TREATMENT LINES AND COMORBIDITIES ARE ASSOCIATED WITH SERIOUS INFECTIONS AND RISK FOR ASPERGILOSIS IN CLL PATIENTS TREATED WITH BCR INHIBITORS IN REAL LIFE

J. Badiola*, P. González-Sierra, J.M. Puerta-Puerta, P. García-Martín, F. Hernández-Mohedo, C. Alarcón-Payer, M. Jurado-Chacón

Hematology, UGC intercentros Hospital Universitario Virgen de las Nieves-Nuevo San Cecilio, Granada, Spain

Background: In addition to blocking signals of cell proliferation, BCR tyrosine kinases inhibitors (BCR inhibitors) also inhibit other signalling pathways, such as toll-like receptors, which are essential for the control of infections. There are few real-life data on the infectious risk associated to ibrutinib and idelalisib.
Aims: To analyse the incidence of the infections in patients receiving treatment with BCR inhibitors and to identify predisposing factors for the development of infections in these patients.
Methods: Data were collected retrospectively, including patients diagnosed with chronic lymphocytic leukemia (CLL) who have received BCR inhibitors for more than 1 month, in Virgen de las Nieves University Hospital in Granada (Spain), from June 2015 to February 2018. Patients received ibrutinib in monotherapy and/or idelalisib-rituximab, and prophylaxis with aciclovir and trimethoprim/sulphamethoxazole.
Results: 22 patients were treated with BCR inhibitors: 11 with ibrutinib, 6 with idelalisib-rituximab and 5 with both treatments, sequentially. Patient characteristics are shown in Table 1. During the follow-up period, 33 episodes of infections occurred, with 20 of them (60.6%) requiring hospital admission and occurring in 11 patients. The focus and etiology are shown in Graph 1. The mean number of days of treatment prior to the first episode of infection (grade ≥3) was 101 days, 54.5% and 27.3% of them after 3 and 6 months, respectively. We observed a positive correlation between the probability of infection (grade ≥3) and the CIRS score ($p<0.05$), and also an almost statistically significant and positive correlation between the probability of infection and the number of previous treatment lines ($p=0.051$). Age, cytogenetic status, type of BCR inhibitor and the diagnosis-to-treatment time, have were not predictive factors of hospital admission. Pulmonary aspergillosis was diagnosed in 4 patients (18.2%), with a trend for a correlation between the risk for this fungal infection and the CIRS score ($p=0.08$) and the number of previous treatment lines ($p=0.054$). Finally, infection-related global mortality was 27.3% (6 patients) due to pulmonary aspergillosis (2 patients), bloodstream infection by *Enterococcus faecium* (1 patient), varicella-zoster virus (1 patient), flu (1 patient) and respiratory infection without clear etiology (1 patient). The average number of days from the start of treatment to death was 298 days.

Table 1. Clinical characteristics of the patients (average).

Male 54.5%	Age 67 years	CIRS score 8.3	CIRS score 8.3
Treatment with ibrutinib and idelalisib-rituximab 72.7% and 50%	Nº of previous treatment lines 2.1	17p-/TP53 mutated 54.5%	

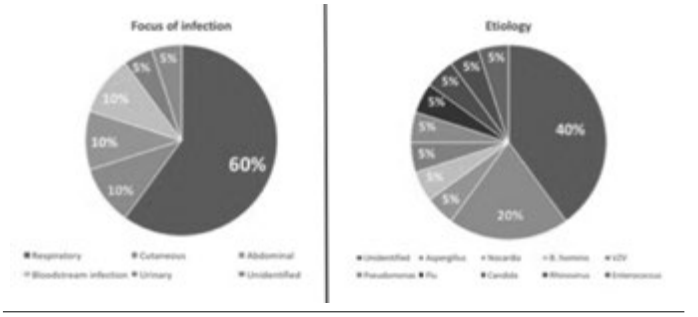

Figure 1.

Summary/Conclusion: Infectious complications were greater than expected, being the main cause of discontinuation. Furthermore, they required hospital admission in more than half of the cases with a considerable mortality. CIRS score and the number of previous treatment lines were predictors of serious infections. Therefore, it seems advisable for patients with multiple treatments and comorbidities not to delay the treatment with BCR inhibitors to avoid infectious complications that may cause treatment discontinuation. With the high incidence of pulmonary aspergillosis in our series, specific strategies for the early detection, treatment and prophylaxis should be adopted. More studies in real-life settings are needed.

PB1879

IMMEDIATE AND LONG-TERM OUTCOMES OF SPLENECTOMY IN PATIENTS WITH NON-HODGKIN LYMPHOMA AND CHRONIC LYMPHOCYTIC LEUKEMIA COMPLICATED BY AUTOIMMUNE HEMOLYTIC ANEMIA

Y. Yevstakhevych[1,*], I. Yevstakhevych[1], Y. Vygovska[1], M. Semerak[1], O. Petronchak[2], V. Loginskiy[1]

[1]SI "Institute of Blood Pathology and Transfusion Medicine NAMS of Ukraine", L'viv, [2]Lviv State Oncology Regional Treatment and Diagnostic Center, L/viv, Ukraine

Background: Autoimmune hemolytic anemia (AIHA) is associated with non-Hodgkin lymphoma (NHL) and with chronic lymphocytic leukemia (CLL) in 2-3% and 5-10% of cases, resp. The most effective treatment for these diseases is chemotherapy with corticosteroid hormones. However, the presence of AIHA in combination with massive splenomegaly may significantly reduce the efficacy of cytostatics. In such cases, splenectomy becomes a reasonable treatment of choice.
Aims: To conduct a retrospective analysis of immediate and long-term outcomes of splenectomy in patients with CLL and NHL, complicated by AIHA.
Methods: 10 patients with NHL and 14 patients with CLL, complicated by AIHA (warm-type) underwent splenectomy.
Results: Splenectomy (SE) proved effective in 12 (85.7%) patients with CLL and AIHA: a big tumor mass was resected, hemolysis was suppressed, hemoglobin level normalized or increased, and platelet count normalized in patients with Rai IV stage. One patient with Rai III stage died of acute adrenal insufficiency three days following operation. As shown by the evaluation of long-term outcomes of SE, median event-free survival (EFS) reached 12.0 months (duration of follow-up was 1-26 months), and median overall survival (OS) reached 25.5 months (duration of follow-up was 2-256 months); there were four (33.3%) patients with a 2-year survival, one (8.3%) patient with a 5-year survival, and two (16.7%) patients with a 10-year survival. Mean post-splenectomy survival in patients with Rai III and IV stage reached 77.6 and 54.5 months, resp. Eight (57.1%) patients were initiated on chemotherapy following 1-14 months after SE, and one patient has been alive for 256 months after surgery with no supportive therapy but complaining of frequent acure respiratory infections. Eight (57.1%) patients with CLL and AIHA died following 2-32 months after SE. Seven patients died due to progression of underlying disease, whereas the relapse of hemolysis was observed just in a single patient. One patient died following 26 months after operation of OPSI-syndrome with a clinical manifestation of severe septic shock. SE was effective in 100% patients with NHL and AIHA: hemolysis was suppressed, hemoglobin level increased; in patients with leukopenia, their leukocyte count normalized, and their abdominal discomfort due to an increased spleen weight disappeared. During the first-year postoperatively, just one patient required cytostatic treatment. As shown by the evaluation of long-term outcomes of SE in patients with NHL and AIHA, EFS reached 29.0 months [12.0-49.0 months], and OS reached 31.0 months [18.1-52.2 months] with a 3-year survival in 45% patients and a 5-year survival in 22% patients. The shortest postoperative survival (3 months) was observed in a patient with nodal marginal zone lymphoma, and the best outcome was achieved in splenic marginal zone lymphoma (SMZL): the patient has been living for 206 months after SE in the condition of a complete clinical remission without any treatment. One patient with SMZL died following 9 months after SE of OPSI-syndrome. Patients with diffuse large B-cell lymphoma (DLBCL, 6 cases) showed a low median of overall survival (26 months), despite of promising immediate outcomes of SE.
Summary/Conclusion: Splenectomy remains to be a leading treatment of choice in the management of chronic lymphoid neoplasias, complicated by AIHA and massive splenomegaly. Long-term outcomes are worse in patients with CLL and Rai IV stage of AIHA. In patients with NHL, complicated by AIHA, the efficacy of operation depends on the type of lymphoma.

PB1880

COPY NUMBER ALTERATIONS DETECTED BY A MULTIPLEX PCR GENOTYPING METHOD AND FISH IN CHRONIC LYMPHOCYTIC LEUKEMIA

L. Fan*, S. Qin, Y. Miao, X. Du, H. Yang, H. Qiu, L. Wang, W. Xu, J. Li

Department of Hematology, the First Affiliated Hospital of Nanjing Medical University, Jiangsu Province Hospital, Nanjing, China

Background: Copy number alteration (CNA) is related with the occurrence and progression of chronic lymphocytic leukemia (CLL) patients. The acquisition of these genomic aberrations is mostly by fluorescence *in situ* hybridization(FISH).
Aims: The purpose of this study was to introduce the AccuCopy method in detecting the CNA in CLL and to compare the usefulness with FISH.
Methods: One hundred chemotherapy-naïve CLL patients were enrolled in this study. Both FISH and AccuCopy were applied on all of them.
Results: AccuCopy was able to identify all del(17p) patients confirmed by FISH and patients with high frequencies of del(11q) (by FISH and patients with high frequencies of del(11q) (40%), respectively). Furthermore, CNA identified 1 sample with a low number of del(17p) cells below the positive cut-off value by FISH, which was accompanied by TP53 mutation.
Summary/Conclusion: Our results suggest that AccuCopy is equally efficient in assessing del(17p) and high frequencies of del(11q) compared to FISH. Besides, we detected 2 deletions and 3 insertions of SETD2 in the patient cohort. Patients carrying SETD2 aberrations showed a higher level of thymidine kinase 1($p<0.001$), C-reactive protein($p<0.001$) and Erythrocyte Sedimentation Rate($p=0.005$). The SETD2 aberrations also correlates with more complexkaryotype(20.0% *vs* 1.8%)($p=0.012$), more MYD88 mutation(33.3% *vs* 2.9%)($p=0.008$) and a higher ZAP70 percentage($p=0.011$). More CNAs need to be validated using this method.

IMMUNOLOGICAL RECONSTITUTION AND PLATELET DISFUNCTION DURING IBRUTINIB IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

I. Innocenti[1,*], F. Autore[1], M.A. Alberelli[2], R. Pasquale[3], A. Corbingi[1], B. Di Giacomo[4], S. Bellesi[4], F. Corrente[4], S. Sica[4], E. De Candia[5], L. Laurenti[4]

[1]Department of Hematology, Catholic University of Sacred Heart, Rome/ Institute of Hematology, [2]Departement of Oncology and Hematology, Catholic University of Sacred Heart, Rome, Rome, [3]Department of Hematology, IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milan, [4]Department of Hematology, Catholic University of Sacred Heart, Rome/ Institute of Hematology, [5]Department of Oncology and Hematology, Catholic University of Sacred Heart, Rome, Italy

Background: Chronic Lymphocytic Leukemia (CLL) is characterized by immune disregulation, often including hypogammaglobulinemia, which contributes to a high rate of infections. Ibrutinib (IBR) seems to generate partial reconstitution of normal B cells and humoral immunity, expecially increase of IgA, in CLL. Frequent IBR associated side-effects are bleeding events, usually mild (Common Toxicity Criteria (CTC) grade1-2), rarely severe (grade3-4). A defect of platelet function, namely an inhibition of Btk-and Tec-mediated signaling downstream platelet glycoproteins GPVI and GPIb, has been hypothesized to cause these bleedings.
Aims: To investigate immune reconstitution and to characterize clinical and laboratory features of platelet dysfunction during IBR.
Methods: We report our monocentric retrospective study on immunological recovery and bleeding in CLL patients (pts) treated with IBR. From May 2014 to December 2017 we treated 27 pts with IBR for progressive naïve CLL if pts harboring del17p/TP53 mutation or with relapsed or refractory disease. In these pts before and 1, 3, 6, 9 and 12 months after beginning of therapy immunological reconstitution was investigated by measuring IgG, IgM, IgA levels, CD3 T lymphocytes, CD4 and CD8 T-helper and T-suppressor subset, B lymphocytes CD19+ and NK lymphocytes CD16/56+ by flow cytometry and platelet dysfunction was investigated by light transmission aggregometry using platelet-rich plasma and ADP, PAR1-AP, Collagen, Arachidonic Acid, ristocetin as platelet agonists. At each time point the grade of bleeding was measured by CTC score. No pts received concomitant antiplatelet or anticoagulant therapy.
Results: Immunoglobulin levels did not show any change during the study period. Median values were constantly below the normal range during IBR. Immunological reconstitution showed a rapid increse of CD19+ lymphocytes above the normal range after 1 month of IBR and rapidly decreased to normal values. CD3+ lymphocytes remained into the normal from baseline to 12 months during IBR, the subset CD4+ decreased from months 3 to 12 with median values below the normal range, on the contrary CD8 showed a progressive increase during the same period with median values into the normal range. CD16/56+ were into the normal range during the study period. We recorded CTC grade 1 or 2 bleedings (bruising, petechiae, conjunctival and retinal hemorrhage, rectal bleeding) in 18 pts; no pts needed IBR interruption or dose reduction. All pts displayed severe impairment of collagen induced aggregation during IBR. On the contrary, the aggregation by low-dose ADP significantly improved. The aggregation by PAR1-AP, ristocetin and arachidonic acid was unchanged before and under IBR. In 18 pts the vWF:Ag and RiCo were high at the onset of the disease and reduced up to normal values under IBR.
Summary/Conclusion: There was no improvement of humural immunity in our pts even after 12 months of IBR, after response to therapy. As expected, B-lymphocytes rapidly decreased up to the normal range after 1 month; T-cell compartment remained within normal values, with a trend toward an increase of T-Suppressor and a reduction of T-Helper after 12 months of treatment, which contributes to cellular immune reconstitution. Our study showed minor bleedings in pts treated with IBR. A severe impairment of collagen-induced aggregation was caused by IBR, which was counteracted by amelioration of ADP-induced aggregation. Finally, pts under anticoagulant or antiplatelet treatment might need be carefully monitored by clinical and laboratory evaluation.

METHOD COMPARISON OF A NOVEL SLIDE-BASED INTEGRATED HEMATOLOGY ANALYZER AND A FLOW CYTOMETRY-BASED SYSTEM USING SAMPLES WITH TARGETED MEDICAL CONDITIONS

H. Russcher[1,*], T. Khartabil[2], D. Bracco[2], T. Allen[2]

[1]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [2]Roche Diagnostics, Westborough, United States

Background: The **cobas m** 511 integrated hematology analyzer (**cobas m** 511 system) is a novel slide-based system that performs a CBC, WBC differential, reticulocyte count, and nucleated RBC count using digital analysis.
Aims: This single-center study investigated whether the **cobas m** 511 system delivered comparable results to the Sysmex® XN-10 Automated Hematology Analyzer using samples from patients with medical conditions.
Methods: Laboratory hematology results were reviewed to identify subjects with 23 targeted medical conditions (including hematological malignancies and disorders of cell numbers and function). Residual whole blood samples (n=130) were processed on both systems within 8 hours of venipuncture. Consistent with CLSI EP09-A3, a method comparison was used to assess the correlation and bias between the systems for all parameters. Individual patient parameter results that were valid on both instruments were included.
Results: All 26 reportable parameters evaluated showed good-to-excellent correlation between the automated results of the **cobas m** 511 system and Sysmex Analyzer, with no significant bias (**Table 1**).

Table 1. Cobas m 511 *vs* Sysmex Analyzer results.

Parameter [units]	Sample range	Pearson's R	Intercept	Slope

Data for%NRBC,%NEUT,%LYMPH,%MONO,%EO,%BASO, and%RET not shown

Summary/Conclusion: The **cobas m** 511 system and Sysmex Analyzer produce comparable results for samples with targeted medical conditions. This demonstrates the robustness of the **cobas m** 511 system when abnormal samples are encountered.

PB1883

ANALYSIS OF PERCENT IDENTITY OF IGHV MUTATION AS PROGNOSTIC FACTOR IN CLL PATIENTS TREATED WITH FLUDARABINE, CYCLOFOSFAMIDE AND RITUXIMAB: A SINGLE CENTRE EXPERIENCE

A. Giordano*, P. Curci, R. Rizzi, M. Delia, T. Perrone, M.A. Urbano, S. Mallano, V. Carluccio, A. Mestice, E. Minervini, F. Albano, G. Specchia

Haematology, University, Bari, Italy

Background: The mutation status of the immunoglobulin heavy chain variable region gene (IGHV) is an established prognostic factor in patients with chronic lymphocytic leukaemia (CLL). The degree of somatic hypermutation, determined as percent sequence identity to germline in IGHV (IGHV%) is analyzed in clinical practice. Currently CLL with<98% IGVH identity are considered "mutated" and CLL patients with >98% IGHV identity are considered "unmutated. " Recent data have assessed the prognostic role of IGHV% as a continuous variable in CLL patients treated with fludarabine, cyclophosphamide and rituximab (FCR).
Aims: In our study we investigated the prognostic significance of absolute percent identity of somatic of IGHV mutation on Progression Free Survival (PFS) and Overall Survival (OS) in unmutated CLL patients (pts) treated with frontline FCR in our Institution.
Methods: We retrospectively evaluated 73 pts with CLL treated with frontline FCR at the University Hospital of Bari (Italy) with a median of 5 years follow-up. The mutational status of the IGHV was studied in all pts and the degree of somatic hypermutation of IGHV was determined as percent identity from the germline sequence. Pts were divided in mutated and unmutated using a cut-off of 98% sequence identity. Among unmutated pts (identity sequence >98%) we selected two groups: the first one between 98% and 99% (IGHV-98-99%) and the second one with identity range between 99% and 100% (IGHV-99-100%), respectively. PFS and OS were calculate and compared between the two groups.
Results: Among the 73 CLL pts treated with frontline FCR 48 pts (65%) with unmutated IGHV CLL were identified; among them, 20 pts (41%) and 28 (59%) belonged to IGHV 98-99% and IGHV 99-100% group, respectively. No significant differences were observed (p=ns) in terms of PFS and OS between the two groups.
Summary/Conclusion: In our study no difference in terms of survival was observed in unmutated IGHV CLL pts on the basis of the percent identity of IGHV mutation for distinguishing two classes of risk. Further studies and more consistent cohorts of pts are warranted to confirm these data.

PB1884

DOES THE DOSE MODIFICATION OF FLUDARABINE, CYCLOPHOSPHAMIDE, RITUXIMAB (FCR) IMPACT TREATMENT OUTCOME IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA? ANSWER BASED ON SINGLE CENTER "REAL-LIFE" DATA

V. Vukovic[1,*], D. Antic[1,2], V. Djurasinovic[1,2], Z. Bukumiric[3], M. Dencic-Fekete[1], T. Dragovic-Ivancevic[1], M. Todorovic-Balint[1,2], J. Bila[1,2], A. Sretenovic[1], M. Smiljanic[1], J. Jelicic[1], B. Mihaljevic[1,2]

[1]Clinic for Hematology, Clinical Center of Serbia, [2]Medical Faculty, University of Belgrade, Belgrade, Serbia, [3]Institute for Medical Statistics and Informatics, Medical Faculty, University of Belgrade, Belgrade, Serbia

Background: There are little published …real life" data about fludarabine, cyclophosphamide, and rituximab (FCR) combination in patients with chronic lymphocytic leukemia (CLL).
Aims: Herein, we present single-center experience based on long-term follow up of 170 CLL pts treated with FCR with focus on side effects and their impact on the outcome.
Methods: In this retrospective study, we analyzed data from 170 pts with CLL treated with FCR, mostly as a first-line treatment pointing at the correlation between side effects frequency, dosage, and treatment outcome.
Results: Median follow-up was 49 months (range, 2-180). Male/female ratio was 2.8:1 and median age before treatment commencement was 61 year, while 72% of pts were younger than 65 years. Unfavourable cytogenetic profile (del17p and/or del11q) carried 25% of patients. Most of the pts (72%) received FCR as a first-line treatment. Thirty-five percent of patients had a dose reduction of FC from the beginning (82%) or during the treatment (18%), most of them (87%) of >25% of the expected full dose. More than a half dose reductions were due to decreased creatinine clearance, in 18% the reason was neutropenia and/or infections, 13% physician's decision and 15% for other reasons. A hundred and ten (67%) pts completed their treatment with 6 FCR cycles, but only 72 (42%) pts received 6 cycles of full-dose FCR. Fifty-six percent of pts at least once received granulocyte colony-stimulating factor (GCSF) for neutropenia grade 3 or 4, 45% of pts had at least one episode of prolonged neutropenia, 16% exhibited late-onset neutropenia, while 28% of pts had infection that caused treatment delay and/or interruption, and/or hospitalization. Neutropenia occurrence was not related to sex, age, comorbidity status, leukocyte count, or cytogenetic profile, but it was significantly more frequent in pts who had already been treated with some chemotherapy regimen (p= 0.035). It occurred significantly more often in pts who did not complete their treatment with 6 cycles (67% *vs* 50%; p=0.046). Treatment delay was observed in almost half of pts (48%), mostly due to severe neutropenia and infections, and in 90% of pts, it happened for the first time after some of the first 4 cycles. Thirty-four percent of pts experienced treatment discontinuation, 60% of them due to cytopenia(s) and/or infections and 22% due to the resistant or progressive disease. The overall response rate was 70,6%, equally split between complete (CR) and partial response (PR). When observing untreated pts, CR was achieved in 46,6% in contrary to 10,9% of previously treated pts (p<0.001). In our group, cytogenetic profile predicted treatment response only in treatment-naïve pts (p<0.001 *vs* p=0.376 for previously treated). Pts who received 6 cycles of full-dose FCR experienced significantly better treatment response (p<0.001). Treatment delay had not been shown to change the outcome when we observed the whole group and pts with

favorable cytogenetic, but when the group was further restricted on pts received full-dose 6 FCR cycles, the adverse impact of treatment delay on outcome was statistically significant (p=0.024). Treatment interruption significantly decreased CR rate (12% *vs* 46%; p<0.001).
Summary/Conclusion: In "real-life" setting treatment with FCR protocol is severely compromised with myelosuppression and infective complications which can considerably influence its therapeutic effect. Further studies are warranted to define risk-factors for myelosuppression after FCR.

PB1885

SAFETY AND EFFICACY OF BENDAMUSTINE AND RITUXIMAB COMBINATION CHEMOTHERAPY AS FIRST LINE TREATMENT IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA: A SINGLE CENTRE EXPERIENCE FROM NORTH INDIA

A. Kumar Tripathi[1,*], S. Verma[1], R. Kushwaha[2], N. Kumar[1], S. Kumar[1], S. Srivastawa[1], V. Singh[3]

[1]Clinical haematology, [2]Pathology, [3]Community Medicine, K.G. Medical University Lucknow India, Lucknow, India

Background: Chronic Lymphocytic Leukemia (CLL) is one of the most common chronic lymphoproliferative disorder (CLPD) in India and the most common CLPD in the west. Treatment of CLL has changed over 2 decades from single agent alkylating compound to combination chemo like Fludarabine, Cyclophosphamide, and Rituximab (FCR) or, Bendamustine and Rituximab based treatment depending on comorbidities and diseases cytogenetic risk. BR chemotherapy has shown impressive results in CLL patient in many phase 2 studies. FCR regimen has many side effects including severe immunosuppression and profound cytopenias. BR has been proven to be better than FCR in CLL10 trial especially in elderly patients with comorbidities. We analysed our "real world" response data of B+R chemotherapy in Indian patients with CLL outside a clinical trial.
Aims: The aim of this study was to analyse safety and efficacy of Bendamustine and Rituximab (B+R) chemotherapy in patients with previously untreated CLL
Methods: We retrospectively analysed the departmental data of all CLL patients who received B+R as the first line treatment. Thirty six patients receiving at least IV cycles of B+R chemo between December 2012 to September 2017 were included in the study. Bendamustine was administered at a dose of 90 mg/m2 on days 1 and 2 combined with 375mg/m2 Rituximab on day 1 in a 28 days cycle. Baseline IGHV mutational status and FISH analysis was not done and MRD was not assessed. Responses were analysed at end of IV-VI cycles of chemo by clinical examination and haematological parameters. Response rates were defined based on IWGCLL response criteria for CR, PR and stable disease. Progression free survival and Overall survival was analysed using Kaplan Meier survival analysis.
Results: Thirty six patients were included in the study with the median age of 55 years (34-75 years). Only 3 patients (8.3%) were above 70 years of age. Most patients belonged to Rai stage III /IV (80%) and Binet C (80%) stage. Mean Hb was 104g/L (26-154), mean total WBC count 144x10^9/L (66-390) and platelet count 50x10^9/L (30-200).Median number of chemotherapy cycles administered were 6 (range 4-12). Overall response rate was 100% with CR and PR rates of 41% & 59% at the end of 4-6 cycles of chemotherapy. Major side effects were cytopenias of any grade in 56% (grade 3 in 25%), febrile neutropenia in 16% and skin toxicities 36% (11% having grade 3 skin toxicity). At the median observation period of 24 month median PFS was 40 months and 70% of patients were surviving. Most common cause of death was progressive disease in 10 patients (27%) and febrile neutropenia in 2 patients (5.5%).
Summary/Conclusion: B+R chemotherapy is well tolerated by previously untreated Indian patients of CLL with impressive response rates, long progression free survival, and manageable side effects in a real world scenario outside a clinical trial.

PB1886

IBRUTINIB IN THE TREATMENT OF EARLY RELAPSE OF CHRONIC LYMPHOCYTIC LEUKEMIA

N. Timofeeva*, E. Stadnik, V. Strugov, A. Zaritskey

Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation

Background: Despite the success of CLL treatment with fludarabine and bendamustine-containing regimens, about 25% of patients had relapsed within the first 24 monthsafter the end of the first-line therapy.In this group of patients PFS after standard "salvage therapy" is 6-18 months,overall survival is extremely low-13-47 months.???The lack of effective approaches to second-line therapy for patients with earlyrelapses of CLL has led to the application of new agent in clinical practice -ibrutinib. Despite the success of CLL treatment with fludarabine and bendamustine-containing regimens, about 25% of patients had relapsed within the first 24 monthsafter the end of the first-line therapy. In this group of patients PFS after standard "salvage therapy" is 6-18 months, overall survival is extremely low-13-47 months. The lack of effective approaches to second-line therapy for patients with earlyrelapses of CLL has led to the application of new agent in clinical practice-ibrutinib.
Aims: To estimate ibrutinib efficacy in the treatment of early CLL relapses and in patients with ≥2 lines of preceding therapy. Analysis of treatment results in patients with del(17p) and monitoring of minimal residual disease (MRD) and ibrutinib safety profile.
Methods: The analysis included the results of ibrutinib treatment in 31 patients with CLL. Twenty eight patients were treated by bendamustine and fludarabine containing regimens. The median prior treatment lines were 2 (range 1–10). The indications for the treatment initiation were the fi rst early relapse in 51% of cases (n=16) and a relapse after 2 and more lines of therapy in 49% of cases (n=15). Ibrutinib was administered in mono- (n=15) and combined therapy (n=14) as well as in the R-BAC scheme (n=2). Using FISH analysis del(17p) was found in 9 patients (34%).
Results: Within the median follow up of 18 months (range 7-42+) the overall survival (OS) rate was reported to be 87%, and the progression-free survival (PFS) rate was 7%. The maximum MRD after a year of ibrutinib treatment was observed in case of combination with immunochemotherapy (e.g., R-BAC). Within the period of 18 months OS rate was 100%, in the patient group with early relapses and 66% in the group with a relapse after 2 and more therapy lines (p=0.02). Within the same examination period PFS was signifi cantly higher (94%) in the patient group with early relapses compared to the previously treated patients (60%) (p=0.034). The most common adverse events were grade 1–2 purpura (30%), grade 1–2 diarrhea (10%), atrial fi brillation paroxysms (10%) and arterial hypertension (10%). Severe infectious complications registered in 6% (n=3) patients were successfully solved in the course of combined antibacterial and antimycotic treatment.

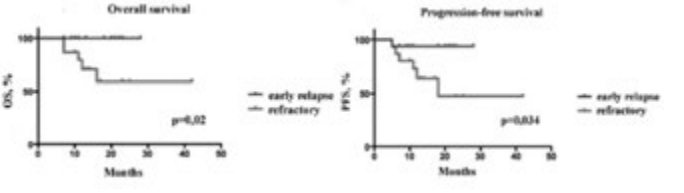

Figure 1.

Summary/Conclusion: Ibrutinib was shown to be effective drug for treatment of relapsed CLL. The OS and PFS values were more favourable in patients with early relapses compared to the patients with relapses after ≥2 lines of therapy prior to ibrutinib treatment. The maximum elimination of the tumor clone was observed after combined ibrutinib/immunochemotherapy treatment. The tolerance of ibrutinib was reported to be satisfactory with acceptable toxicity profile. No mortality due to infection complications was observed.

PB1887

COMPARISON OF CLINICAL FEATURES AND SURVIVAL BETWEEN YOUNG AND OLD CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS: A SINGLE CENTRE STUDY FROM TURKEY

R. Eren[1,*], A. Karışmaz[1], D. Karataş[2], M.H. Doğu[1], S. Altındal[1], O. Yokuş[1], E. Suyanı[1]

[1]Hematology, Univeristy of Health Sciences, İstanbul Training and Research Hospital, [2]İnternal Medicine, Univeristy of Health Sciences, Bağcılar Training and Research Hospital, İstanbul, Turkey

Background: The average age of the patients at the time of diagnosis is 72 and the incidence of CLL increases with age. Comorbidities, which increase by age, including coronary artery disease, heart failure, diabetes mellitus, chronic obstructive pulmonary disease and cognitive geriatric syndromes influence the performance status of the elderly patients leading to negative impact on treatment continuation and survival.
Aims: We aimed to investigate the clinical characteristics, the rate of treatment demand, time to treatment and mortality rates differ between c CLL patients<65 years and ≥65 years, which is the cut-off age for the definition of elderly by World Health Organization

Methods: A hundred and thirty-seven patients who were diagnosed and followed with the diagnosis of CLL were included in this retrospective analysis. The patients were diagnosed according to International Workshop on Chronic Lymphocytic Leukemia (iwCLL) criteria and Rai staging system was used for disease-staging. Patients were divided into two groups based on the World Health Organization (WHO) definition of elderly, which starts at age 65. Clinical characteristics, treatment demand, time to treatment and mortality rates of the two groups were compared. In a subgroup analysis, patients receiving treatment were also analysed according to age.
Results: There were 63 (46%) patients aged<65 years and 74 (54%) patients ≥65 years. Two groups were comparable in term gender, Rai stage, WBC, ALC, Hgb level, Plt count, presence of splenomegaly, lymphadenopathy, Del 13q14, Del 11q22, Del 17p and Trisomy 12, time to treatment and treatment demand (p>0.05). Even though the difference was statistically insignificant, 28.6% (18/63) of the patients<65 required treatment, while this rate was 44.6% (33/74) for patients ≥65. We also analysed the patients, who received treatment, according to the age groups When we divided patients who received treatment into two groups as<65 years and ≥65 years the two groups were similarly comparable in terms of gender, age, WBC, ALC, Hgb, plt, Rai stage, presence of splenomegaly, lymphadenopathy, Del 13q14, Del 11q22, Del 17p and Trisomy 12, and time to treatment (p>0,05)
Summary/Conclusion: We found no difference in CLL patients who are younger and older than 65 in terms of clinical characteristics, disease stage, time to treatment and treatment demand. Mortality rates were higher in older patients with the upshot of comorbid diseases. The major limitations of our study were the limited number of patients and conducting with retrospective chart review.

PB1888

SAFETY PROFILE OF IBRUTINIB: A RETROSPECTIVE ANALYSIS OF 31 PATIENTS

J. Uriarte*, S. Herraez, C. Barrenetxea, A. Blanco, J.A. Marquez, Z. Díez Gallarreta, I. Leal, C. Alonso, L. Hernandez, F. Marco

Hematology, Hospital Universitario Basurto, Bilbao, Spain

Background: Ibrutinib is an irreversible molecular inhibitor of Bruton's tyrosine kinase (ITK), which has altered the treatment paradigm for hematological diseases such as Chronic Lymphocytic Leukemia (CLL), Mantle Cell Lymphoma (MCL), and Waldeström's Macroglobulinemia (WM). Due to its recent incorporation, long-term safety profile has not yet been defined, although the most frequently reported adverse effects are the following: diarrhea, neutropenia, mild bleeding, exanthema and musculoskeletal pain.
Aims: Our aim is to analyze Ibrutinib's adverse effects in our group of patients, paying special attention to cardiological, infectious and hemorrhagic ones.
Methods: It is a descriptive, observational and retrospective study on the use of Ibrutinib in our hospital between February 2016 and February 2018. We analyzed patient's profile (age, sex, previous cardiological disease and anticoagulant and antiplatelet therapy, hematological diagnosis, and previous treatment lines), duration of Ibrutinib-based therapy and level of response achieved, adverse effects, treatment interruptions and dose reduction (if needed).

Table 1.

Adverse effects		Management
No adverse effects	18	
Cardiac toxicity		
Isolated atrial fibrillation de novo	1	Temporary treatment discontinuation (TTD)
Atrial fibrillation + Congestive heart failure	2	TTD, admission, ASA TTD
Atypical chest pain	1	Definitive treatment
Congestive heart failure worsening	1	discontinuation (DTD)
Infectious toxicity		
Mild respiratory (not documented)	1	TTD, admission DTD, admission
Pneumocytis jirovecii pneumonia	1	No therapy modifications (NTM)
Mild testicular infection	1	
Other toxicities		
HTA impairment	1	NTM
Diarrhea	2	NTM
Muscle cramps	1	NTM
Peripheral edema	1	Dose reduction

Results: Thirty-one patients were treated with Ibrutinib, of which 74% were male and 26% female, with an average age of 70.5 years (between 48-84). Of the total, four had previous heart disease: Atrial Fibrillation (2), ischemic heart disease (1), and aortic valve insufficiency (1); three were being treated with acetylsalicylic acid (ASA), one with ASA and Clopidogrel, and two with oral anticoagulants (Acenocoumarol/Apixaban). ASA was suspended on the first three cases and Clopidogrel on the fourth one. Treatment indications were the following: CLL (17), MCL (7), WM (4), B-Cell Prolymphocytic Leukemia (2) and Diffuse Large B Cell Lymphoma (1). Of the 31 patients, 8 received Ibrutinib as first-line treatment, 17 as second-line, 4 as third-line and 2 as fourth-line. The average duration of treatment was 7 months (between 0.25-21.5). Inicial dose had to be reduced in one patient due to mild hepatic failure (Child-Pugh A). In terms of response level, 10 achieved complete response, 4 partial response (of which one later progressed), 7 progressed during treatment (4 MCL -as second line-, 3 CLL -as second line-, and 1 B Cell Prolymphocytic Leukemia -as first line-). In the 9 remaining patients, the level of response has not yet been evaluated since they have recently started therapy with Ibrutinib. Adverse effects observed during the treatment period are detailed in the chart (see attached file 1).
Summary/Conclusion: Based on our experience, the use of Ibrutinib has an acceptable toxicity profile, with adverse cardiac effects being the most frequent and serious. For this reason, we consider fundamental previous cardiological assessment of the patients and their close monitoring during the treatment. However, it seems important to note that the majority of adverse effects have occurred in patients in second and third lines of treatment.

PB1889

ASSOCIATION OF INITIAL PROGNOSTIC PARAMETERS AND REQUIREMENT FOR TREATMENT IN CHRONIC LYMPHOCYTIC LEUKEMIA

A. Senturk Yikilmaz[1,*], S.M. Bakanay[1], S. Akinci[2], M. Gündüz[2], S. Küçükyurt Kaya[1], S. Doğan[1], M. Falay[3], I. Dilek[1]

[1]Department of Hematology, Yıldırım Beyazıt University, [2]Department of Hematology, Atatürk Education and Research Hospital, [3]Department of Hematology, Numune Education and Research Hospital, Ankara, Turkey

Background: B-cell chronic lymphocytic leukemia (CLL) is the most common haematological malignancy in advanced age. The clinical course of the disease is highly variable, therefore there is a need to investigate the various prognostic factors. The CLL cell typically expresses CD5, CD19, CD23 and a monoclonal surface Ig (K or λ) while CD20 is moderately/weakly expressed.
Aims: We aimed to analyze the clinical, genetic and immunophenotypic features which might have prognostic value in CLL.
Methods: Between February 2010 and June 2018, 87 cases diagnosed with CLL were retrospectively analyzed. Patients who were followed without treatment (T0 group) and who required at least one line treatment (T) were compared. Patients who required 1 line treatment (T1) were also further compared with patients who required >1 line treatment (T2). Statistical analyzes were performed using chi-square test using SPSS version 16.0 (SPSS Inc., Chicago, IL, USA). A value of less than 0.05 was considered significant.
Results: The mean age of our patient population was 65 (±SD12,8) with Male/Female 56/31. At diagnosis, 68(78.2%) patients were at early stage (0, I, II) and 19 (21.8%) were at advanced stage (III,IV). Del17p, del13q and trisomy 12 were evaluated in 49, 41 and 31 patients and 5, 13 and 4 patients were found out to be positive, respectively. Anemia and thrombocytopenia were present in 25 (28.7%) and 16 (18.4%) patients, respectively. Twenty one (24.1%) patients had B symptoms. Splenomegaly, lymphadenopathy and hepatomegaly were present in 34(39%), 67(77%) and 21(24.1%) patients, respectively. Four of the 15 patients who had direct coombs positivity also had clinical evidence of hemolytic anemia. Four patients had immune thrombocytopenia, 2 of them had concurrent direct coombs positivity and one also had hemolytic anemia. The median Hb, leukocyte and platelet counts were 13.2 gr/dl (4.4-17.5 gr/dl), 23.6x10^9/L (1,7-527x10^9/L) and 200x10^9/L (10-345 10^9/L), respectively. Follow up period was median 38 months (3-180 months). Twenty five (28.7%) patients were treated at the time of diagnosis. Thirty three (37.9%) patients had T1 and 6 (6.9%) patients required T2. The ratio of male patients in group T were significantly higher than female patients (p=0.038). All patients in group T2 were male. More patients in group T had CD38 expression than group T0 (p=0.04). There was no significant difference between the groups in terms of FMC7 and CD11c expressions. Of the 5 patients with del17p, 2 patients required treatment at diagnosis, 2 patients required treatment after 13 and 48 months of follow up, respectively.
Summary/Conclusion: In our CLL patients, requirement for treatment was associated with CD38 expression, del17p positivity at diagnosis and male gender.

PB1890

CHRONIC LYMPHOCYTIC LEUKAEMIA (CLL): AN AUDIT OF COMPLIANCE WITH KEY ASPECTS OF BRITISH SOCIETY FOR HAEMATOLOGY (BSH) GUIDELINES ON DIAGNOSTIC WORK UP

D.S.R. Vohra*, D.H. Patel

Haematology, Royal Albert Edward Infirmary(Wrightington, Wigan and Leigh NHS Trust), Wigan, United Kingdom

Background: Chronic lymphocytic leukaemia (CLL) is a malignant clonal disorder of B lymphocytes with levels greater than $5x10^9$/L ($5x10^3$/microliter) involving the bone marrow and peripheral blood. The incidence of CLL increases with age. Upon diagnosis, British Society for Haematology(BSH) recommends that all patients should have specific tests such as full blood count, reticulocyte count, direct antiglobulin test (DAT), immunophenotype, and serum immunoglobulins. In addition to this, screening for hepatitis B and C, TP53 deletion and a baseline CT scan should be done prior to treatment.
Aims: The aim of the audit is to assess the compliance with key aspects of BSH guidelines on diagnostic work up for CLL.
Methods: Electronic records for 32 patients diagnosed with CLL between January 2016 and May 2017 in Royal Albert Edward Infirmary (England) were analysed.
Results: The demographics show a higher proportion of males 59% (19 of 32 patients) compared to females 41% (13 of 32 patients). Similar studies show a male-to-female ratio of 2:1 which is comparable to our results. The mean age at diagnosis was 72 years. 3 patients (9.4%) had haemoglobin levels below 100g/l of which no patients had a reticulocyte count and direct antiglobulin test done. All 32 patients had an immunophenotype typical of CLL. 8 patients (25%) patients did not have their serum immunoglobulins checked. 3 of 32 patients (9%) received treatment with FCR (Fludarabine, Cyclophosphamide, Rituximab) as first line therapy. Before treatment, all 3 patients had screening for hepatitis B and C, TP53 deletion and baseline CT scan.
Summary/Conclusion: We suggest that patients with low haemoglobin levels should have a direct antiglobulin test and reticulocyte count performed. All patients should have their serum immunoglobulins checked. A diagnostic work up and pre-treatment checklist should be designed to guide specialist teams.

SALIVARY PROTEOMIC PROFILE OF PATIENTS WITH CHRONIC MYELOID LEUKEMIA DISTINGUISHES TKIS RESPONDERS FROM NON-RESPONDERS

F. Perutelli[1,*], A. Cecchettini[2], E. Polizzi[3], S. Grassi[1,4], L. Mattii[5], F. Guerrini[1], E. Ciabatti[1], A. Di Paolo[6], M. Petrini[1], S. Galimberti[1]

[1]Clinical and Experimental Medicine, Hematology, [2]Clinical and Experimental Medicine, Biology, [3]Surgical, Medical, Molecular and Critical Pathology, Biotechnologies, University of Pisa, Pisa, [4]Medical Biotechnologies, University of Siena, Siena, [5]Clinical and Experimental Medicine, Histology, [6]Clinical and Experimental Medicine, Pharmacology, University of Pisa, Pisa, Italy

Background: Today the gold standard analyses to characterize patients affected by chronic myeloid leukemia (CML) require bone marrow samples, however peripheral blood may be used to monitor the molecular response during tyrosine kinase inhibitors (TKIs) treatment. Recent studies have shown that saliva could be an alternative substrate for biomarker detection in many diseases. To date, there are no preemptive studies that investigate the salivary proteomic profile to identify non-responders to TKI therapy in CML.
Aims: The aim is to identify putative response biomarkers in the saliva of CML patients.
Methods: We investigated the salivary expression profile of 176 proteins at two different time points in 2 groups of patients with CML. The first group was represented by 4 patients in stable deep molecular response during TKIs treatment, while the second one included 4 sex and age-matched TKI-failure cases. Analyses were performed at baseline and after 6 months of treatment with TKIs. Proteomic analysis was performed by using albumin- and IgG-depleted saliva samples through a nano-HPLC system coupled with a TripleTOF™ 5600 mass spectrometer. Statistical comparative analysis was performed using PeakView™ Software with SWATH™ Acquisition MicroApp 2.0 and MarkerView™.
Results: Overall, 64 proteins resulted differently expressed in resistant *versus* sensitive cases. As shown in the image, myeloperoxidase (PERM), thymosine beta-4 (TYB4), matrix metalloproteinase-9 (MMP9), peroxiredoxin-2 (PRDX2), catalase (CATA) and macrophage migration inhibitory factor (MIF) were down-regulated, while MMP-9-inhibitor (TIMP1), SPARC-like protein-1 (SPRL1), transgelin-2 (TAGL2), leucocyte elastase inhibitor (ILEU), carbonic anhydrase-6 (CAH6), kallikrein-1 (KLK1) and -11 (KLK11), cadherin-1 (CADH1) and beta-2-microglobulin (B2MG) were over-expressed in resistant patients compared to sensitive ones.

Figure 1.

Summary/Conclusion: Our results show that in resistant patients, proteins implicated in hypoxia of the niche are over-expressed. This may be implied in the induction of resistance to TKIs because of the lower BCR-ABL1 expression. In details, these proteins are involved in differentiation of the osteoblasts (PRDX2, MIF), which are main cellular components of the niche; in myeloid differentiation (TYB4, ILEU, PERM), which is a sign of response to TKIs therapy; in fibrosis of the niche (MMP-9, TIMP1), thus preventing the oxygenation of the leukemic stem cell (LSC) and consequently its protein expression; in tumor-induced angiogenesis (MIF, TAGL2); in LSC quiescence (CATA); in components of the niche microenviroment (SPRL1, CAH6); in

factors that support the adhesion of LSC to the stroma (TAGL2, CADH1). In addition, some of these proteins have been already described as prognostic factors in solid tumors (MIF, KLK1, KLK11) and leukemias (B2MG, MIF, CADH1), while CADH1 seems to be correlated to a better response to imatinib in CML patients. Our data show that proteins traditionally identified in peripheral blood only, can be detected also in the saliva, thus indicating that use of this compartment for characterization of CML patients may be feasible. Moreover, the salivary expression profile in resistant *versus* sensitive cases is significantly different and coherent with their response to TKIs treatment, thus suggesting salivary proteomic profile as a possible method to identify the occurrence of resistance to TKIs. However, further studies are needed to indicate saliva as a valid alternative to peripheral blood and bone marrow to monitor response to TKIs treatment in CML patients.

ASSOCIATION OF PLK1 AND AURORA KINASE INHIBITORS WITH WEE1 INHIBITORS: A NOVEL THERAPEUTIC APPROACH FOR BLAST CRISIS CML

M. Mancini[1,*], S. De Santis[2], C. Monaldi[2], F. Castagnetti[2], L. Bavaro[2], M. Martelli[2], G. Gugliotta[2], G. Rosti[2], E. Tenti[2], M.A. Santucci[2], M. Cavo[2], G. Martinelli[3], S. Soverini[2]

[1]Department of Experimental Diagnostic and Specialty Medicine-DIMES, Department of Experimental Diagnostic and Specialty Medicine-DIMES, University of BolognaInstitute of Hematology "L. e A. Seràgnoli", [2]Department of Experimental Diagnostic and Specialty Medicine-DIMES, Istituto di Ematologia Seràgnoli-DIMES, Bologna, [3]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Meldola, Italy

Background: Polo-like kinases (PLKs) and Aurora kinases (AKs) act as key cell cycle regulators in healthy human cells. In cancer, these protein kinases are often overexpressed and deregulated, thus contributing to uncontrolled cell proliferation, growth and consequent genomic instability. Chronic myeloid leukemia (CML) is a myeloproliferative disorder of hematopoietic stem cell. Despite the striking success of tyrosine kinase inhibitor (TKI) therapy, a small but significant proportion of CML patients may still progress from the chronic phase (CP) to the accelerated phase (AP)and eventually to the blast crisis (BC). This is likely due to cooperating molecular events additional to the initial t(9;22) translocation. Even in the TKi era, CML patients who progress to BC have a poor outcome, hence the urgent need to identify novel therapeutic strategies, targeting alternative signaling pathways important for leukemic cell proliferation are required.
Aims: In this study, a new therapeutic strategy based on AKA or Plk1 inhibition with PHA-739358 (Danusertib) or BI6727 (Volasertib), associated with Wee1 inhibition with AZD1775 was evaluated in K562 cells sensitive (K562-S) and resistant (K562-R) to imatinib and in primary cells from CML patients in BC.
Methods: Protein expression and activation was assessed by Western Blotting. Apoptotic cell death was quantified by annexin V/propidium iodide staining and flow cytometry. Cell cycle progression were evaluated by flow cytometry. Drug cytotoxicity in *ex vivo* experiments was evaluated in clonogenic assays in 1 healthy donor and in 3 CML patients in BC.
Results: Both Danusertib and Volasertib (0.5 μM for 24h) showed cytostatic and cytotoxic effects in CML cells by inducing G2/M-phase arrest and apoptosis. Moreover, they caused a dose- and time-dependent reduction of the G0/G1 cell fraction and an increase of the G2/M fraction. Cell cycle arrest was associated with increased levels of phospho (p)-Chk1 and p-Chk2, p-cyclin B1, p-cdc2 and p-Wee1. Using a Wee1 inhibitor (AZD1775) after 24h treatment with Danusertib and Volasertib 0.5 μM, when cells were arrested in G2 phase and Wee1 was overexpressed and hyper-activated, resulted in a synergistic inhibition of cell viability in both K562-S and -R. AZD1775 combined with either Danusertib or Volasertib caused a time-dependent increase of annexin-V-positive cells by activating the mitochondrial apoptotic pathway as reflected by an increment of Bax expression and induction of the cleavage of caspase-3, -9 and PARP. Moreover, both drug combinations induced a significant increase of the DNA double-strand break marker γH2AX, suggesting that Wee1 inhibition promotes mitosis and propagates genomic instability by forcing the cells through successive replication cycles, ultimately resulting in apoptosis from mitotic catastrophe. Finally, clonogenic assays performed by using CD34+ progenitors from three BC CML patients, showed that PLK1 or AKs inhibition, associated with Wee1 inhibition, reduce the clonogenic activity of the CD34+ compartment in a synergistic way compared to the same drugs administrated alone.
Summary/Conclusion: Taken together, our findings indicate that PLK1 and AKs inhibitors associated with WEE1 inhibition display the potential for being further explored in innovative clinical trials aimed to improve the outcomes of patients with CML in blast crisis, or resistant to multiple lines of TKI therapy.

PB1893

ALTERED EXPRESSION OF JAK-STAT PATHWAY AS POSSIBLE PREDICTIVE MARKER IN PATIENTS AFFECTED BY CHRONIC MYELOID LEUKEMIA RECEIVING TYROSIN KINASE INHIBITORS (TKIS)

S. Grassi[1,*], S. Palumbo[2], V. Mariotti[2], E. Ciabatti[3], F. Guerrini[4], F. Perutelli[4], C. Baratè[3], M. Petrini[4], S. Pellegrini[2], S. Galimberti[4]

[1]Medical Biotechnologies, University of Siena, Siena, [2]Clinical and Experimental Medicine, Clinical Biochemistry and Molecular Biology, University of Pisa, [3]Clinical and Experimental Medicine, Hematology, AOUP, [4]Clinical and Experimental Medicine, Hematology, University of Pisa, Pisa, Italy

Background: The JAK-STAT pathway is involved in the transduction of signals mediated by cytokines, interferons and growth factors with consequent support of neoplastic cell growth and invasion in many types of cancer. Additional implications in inflammation and immunity in the tumor microenvironment have been recently recognized, because this pathway seems to sustain the stem cell maintenance. Moreover, persistent STAT3 activation would confer resistance to therapy with tyrosine kinase inhibitors in chronic myeloid leukemia (CML) by controlling the leukemia stem cell (LSC) self-renewal and favoring its hiding in the bone marrow niche (Groner, 2017). Inhibition of this pathway might represent a potential way to ameliorate the molecular response in warning or failed CML patients or to sustain deep responses in cases tempting the discontinuation of therapy.
Aims: Our purpose was the evaluation of some BCR/ABL1-independent molecular predictive markers of response in CML patients. Thus, we analyzed the expression of 86 genes belonging to the JAK-STAT pathway in 10 cases assessed at diagnosis and after 6 months of therapy with TKIs.

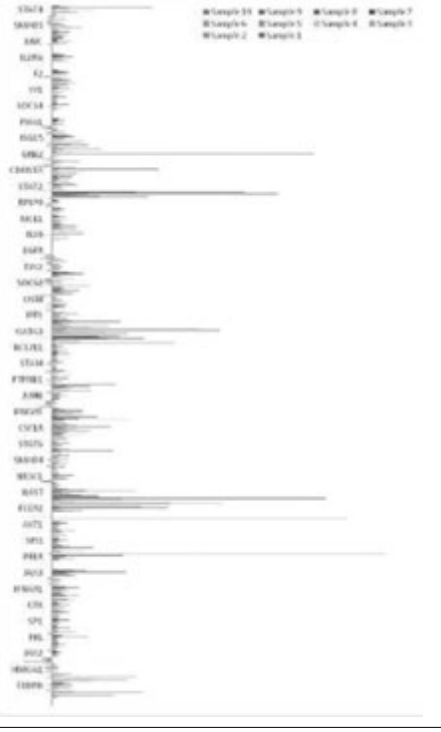

Figure 1.

Methods: 10 patients received TKIs as first-line treatment (7 imatinib, 2 nilotinib, 1 dasatinib). Concomitantly to the BCR/ABL1 transcript, we quantitated the expression level of 86 JAK-STAT genes by RT-qPCR (PrimePCR SYBR® Green assay, Biorad©, Milan, Italy) at baseline and after 6 months of therapy. Expression values were calculated by the Vandesompele method using four housekeeping genes.
Results: According to European Leukemia Network guidelines, after six months of treatment 9 patients were in optimal response and 1 was in failure, and the gene expression analysis showed a relevant deregulation of the pathway. Indeed, 79 genes resulted up-regulated, while only 7 were down-

expressed. To evaluate a possible clinical role of the JAK-STAT pathway, we correlated the gene expression results with the achievement of MR3. At 6 months of treatment, we identified correlation of MR3 with up-regulation of LRG1 (p=0.030), a gene belonging to the *leucine-rich repeat* (LRR) family that is overexpressed during the granulocyte differentiation, and down-regulation of IL2RA (p=0.030) and MPL (p=0.029). IL2RA is involved in the LSC growth and MPL is linked to persistent activation of JAK-STAT. Moreover, the up-regulation in responsive patients also involved the immunity signaling linked to interferon (IFN) receptors complex, and induced interferon-related factors with anti-proliferative and pro-apoptotic effects, such as CSF1R, IRF1, IRF9, and ISG15. The increased expression of GATA3, SOCS3, JAK3 is involved in NK and T cell recruitment as immunology protection in responsive patients. Finally, in responsive cases we observed a significant up-regulation of: 1) OSM, involved in bone remodelling and reduction of fibrosis damaging the LSC survival in the niche and 2) IFN receptor type 1 that is usually expressed in stromal cells as a protection factor against cancer progression.

Summary/Conclusion: In this work, we demonstrated that the JAK-STAT pathway is really implicated in the resistance to TKIs and, on the other hand, that the de-regulation of some genes of this family might be related to the achievement of better molecular responses. This observation could have a practical clinical output, suggesting the effectiveness of the combination of JAK-STAT inhibitors (ruxolitinib or methotrexate) with TKIs in resistant CML patients.

PB1894

BCR-ABL EXON 7 DELETION CAUSES TKI RESISTANCE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

I. Mikhailov*

Faculty of fundamental medicine, Lomonossov Moscow State University, Moscow, Russian Federation

Background: One of the most controversial causes of TKI resistance in patients with CML is the pathogenic BCR- ABL del. c.1086-1270 transcript. This transcript was first described in 2008 in TKI resistant patients (Curvo *et al*., 2008). BCR-ABL del. c.1086-1270 transcript encodes truncated fusion protein BCR-ABL p.R362fs*21 which is an alternative splicing product. It has been shown that such truncated protein is unlikely to have tyrosine kinase activity because of the disfunction of the ATP-binding site (Meggyesi *et al*., 2012). However, we suggest that pathogenic effect of BCR-ABL p.R362fs*21 expression is possible due to the dimerization with a typical protein BCR-ABL p210. Such mechanism has already been proved for the splice variant of serine-threonine kinase BRAF (Poulikakos *et al*., 2011).

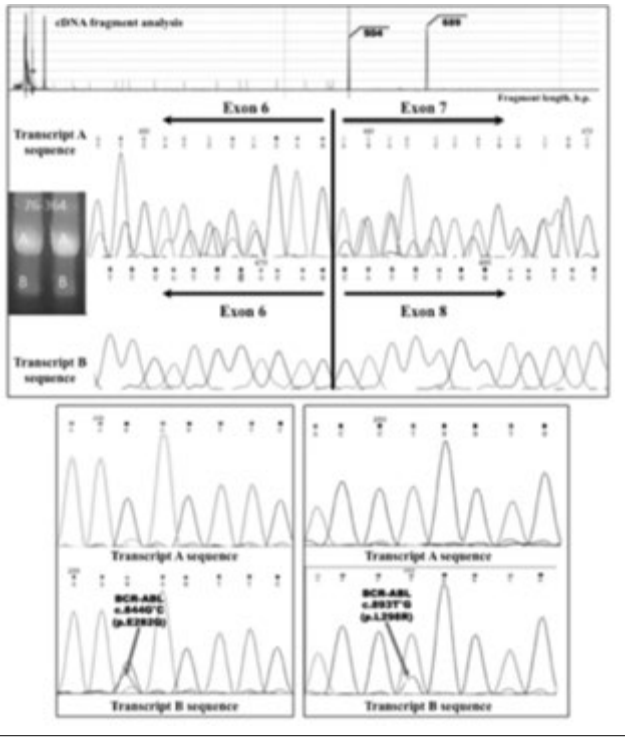

Figure 1.

Aims: To evaluate the pathogenic effect of BCR-ABL del. c.1086-1270 (p.R362fs*21) on TKI resistance formation in Russian patients with CML.

Methods: 33 male and 50 female CML patients (age 24-80) with BCR-ABL transcript level >0.1% were included in the study. BCR-ABL exon 7 deletion was analyzed with two round (nested) PCR followed by Sanger sequencing. Initial screening for deletions was performed by means of fragment analysis (Applied Biosystems 3130).

Results: Fragment analysis detected BCR-ABL del. c.1086-1270 transcript in 32 patients (38%). The ratio of TKI-sensitive to TKI-resistant among these 32 patients was approximately 47% (15 patients) to 53% (17 patients) respectively. Direct sequencing showed the tumor clone, which contains the BCR-ABL1 del.c.1086-1270 always paired with a normal clone of BCR-ABL p210, in all TKI-resistant patients. This fact was verified by the results of agarose gel electrophoresis. We suggest, that these results show an indirect evidence of the dimerization of the protein BCR-ABL del. c.1086-1270 with chimeric protein Bcr-Abl p210. Furthermore, the deletion clone of each TKI-resistant patient always has a point mutation (F317V, F317L, E282Q, M351T, T315I) which is unlikely for the normal clone (Figure 1). This fact contradicts the alternative splicing theory.

Summary/Conclusion: Our results show a definite correlation between the presence of the deletion and TKI-resistance. BCR- ABL1 del.c.1086-1270 is likely to play a trigger-role in TKI-resistance formation: clones with the exon 7 deletion are extremely prone to the accumulation of combined point mutations, which can increase the risk of TKI-resistance formation.

PB1895

DOWN-REGULATION OF MUSASHI2 AFFECTS ON MTOR SIGNALING AND INDUCES APOPTOSIS IN CD34+ CHRONIC MYELOID LEUKEMIA CELLS

M. Mossahebi-Mohammadi[1,2,*], S. Babashah[3]

[1]Hematology and Blood Banking, Faculty of Medical Sciences, Tarbiat Modares University, [2]Sarem Cell Research Center (SCRC), Sarem Woman's Hospital, [3]Department of Molecular Genetics, Faculty of Biological Sciences, Tarbiat Modares University, Tehran, Iran, Islamic Republic Of

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative disease. The high levels of Musashi2 (Msi2) is associated with down-regulation of Numb, a cell-fate determinant gene, in CML cells.

Aims: In current study, we knocked down Msi2 using RNA interference (RNAi) strategy and investigated the effects of this knock down on the expression of mTOR signaling.

Methods: Synthetic double stranded siRNAs designed to target human Msi2 were transfected to CD34 CML cells. Changes in the expression levels of Msi-2, Numb, TOR, and Bcl-2 genes 48h after transfection were evaluated by real-time PCR. Induction of apoptosis in transfected leukemic cells was determined using Annexin-PI staining and flowcytometry analysis.

Results: We found that upon Msi2 suppression, the expression levels of the cell-fate determinant Numb showed significantly increase in CD34+ CML cells. Msi2 down-regulation and subsequent increase in Numb expression levels caused reduction in expression of mTOR, as an oncogenic regulator. In addition, Msi2 down-regulation promoted cell apoptosis via the down-regulation of Bcl-2 expression. We observed that Msi2 downregulation resulted in decreased cell proliferation and elevated rate of apoptiosis in CD34+ CML cells.

Summary/Conclusion: It seems that Msi2 could be an option for targeting CD34+ CML cells and its down-regulation through RNAi strategy may lead to induction of apoptosis in leukemic stem cells. This approach may open up new opportunities for leukemia therapy.

PB1896

WNT PATHWAY IS INVOLVED IN BCR-ABL1-INDEPENDENT RESISTANCE TO TKIS IN CHRONIC MYELOID LEUKEMIA PATIENTS

S. Grassi[1,*], S. Palumbo[2], V. Mariotti[2], E. Ciabatti[3], F. Guerrini[3], C. Baratè[3], M. Petrini[3], S. Pellegrini[2], S. Galimberti[3]

[1]Medical Biotechnologies, University of Siena, Siena, [2]Clinica and Experimental Medicine, clinical biochemistry and clinical molecular biology, [3]Clinica and Experimental Medicine, Hematology, University of Pisa, Pisa, Italy

Background: After the introduction in the clinical practice of tyrosine kinase inhibitors (TKIs),the overall survival of CML patients is really improved, but several mechanisms of resistance have been reported. In addition to BCR-ABL1-related mechanisms (amplification, ABL1 mutations), the persistence of the leukemic stem cell (LSC) in the bone marrow niche is a very

relevant problem. The hypoxia and the presence of immunosuppressive cells in the microenvironment are well-known mechanisms that sustain the LSC; nevertheless, an increasing interest is also put today into the WNT/Beta-catenin pathway, that is necessary to self-renewal of normal cells, but its deregulation also causes leukemogenesis and progression in several types of cancers (Zhao, 2007).

Aims: we decided to assess the expression of 86 genes of the beta-catenin/WNT pathway at diagnosis and after 6 months of treatment with TKIs in a cohort of 10 patients with different responses to treatment.

Methods: Buffy coats obtained from peripheral blood samples of 10 patients (7receiving imatinib, 2 nilotinib, and 1 dasatinib) have been used for the total RNA extraction. In addition to the quantification of the BCR-ABL1/ABL1 ratio%IS, we used RT-q PCR to measure the expression of 86 genes from the WNT pathway (PrimePCR pathway kit, Biorad, Milan, Italy) at diagnosis and after 6 months of therapy. Expression values were calculated by the Vandesompele method using four housekeeping genes. Data have been analyzed by the "Gene Study" PrimePCR analysis software (Biorad).

Results: Five patients achieved an optimal response and five were no responders, according to the European Leukemia Network guidelines. Interestingly, after 6 months of treatment, we observed a de-regulation of 36 genes. Down-expression occurred in 14% of genes, while 79% of genes were up-regulated. When we compared the change of expression with the quality of response to TKIs, a differential expression between patients with or without an optimal response was observed: in the cases without optimal response, we found as up-regulated: 1) FZD7, already known to be responsible for the protection of leukemic CML cell, proliferation and drug resistance in K562 cells; 2) WNT6, that predicts unfavorable survival in solid cancer and whose expression is inversely correlated to the responseto ECF (Epi, cisplatin, 5-fluorouracil) chemotherapy in human gastric cancer cells; 3)WISP1, with anti-apoptotic activity, associated to poor prognosis and advanced stage in glioblastoma. On the other hand, the most frequently down-regulated gene was CSNK1A1, whose aploinsufficiency has been shown to result in a more probable transformation of myelodysplastic syndrome (MDS) in acute myeloid leukemia (AML) and to induce proliferation, invasion and metastasis in multiple myeloma (MM), lymphoma (DLBCL) and AML.

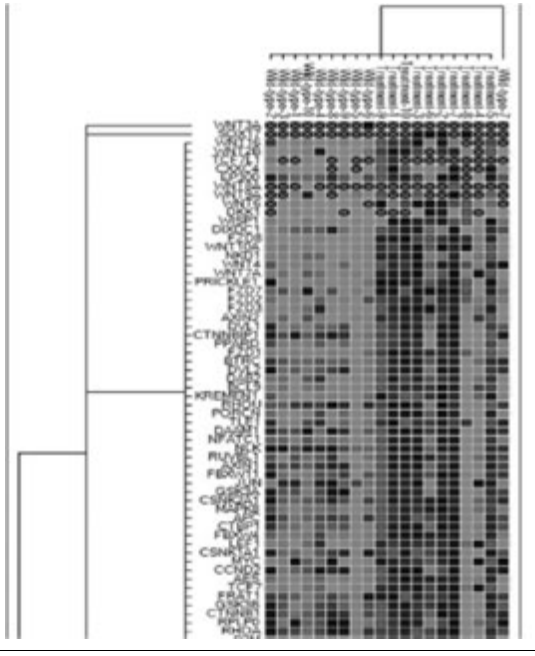

Figure 1.

Summary/Conclusion: With these experiments of gene expression profiling we demonstrated, although in a small group of CML patients, that the beta-catenin /WNT pathway might be relevant to condition the response to TKIs. Obviously, the analysis of a larger number of patients will improve the biological suggestions coming from these preliminary data

PB1897

EFFECTS OF DIFFERENT TKIS ON CHRONIC MYELOID LEUKEMIA STEM CELLS AND TKIS DISCONTINUATION

L. Jiang[1,*], Q. Li[2], J. Cui[1], Y. You[1], Z. Zhong[1], X. Zhu[3], P. Zou[1]

[1]Institute of Hematology, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, [2]Department of Hematology, Wuhan No.[1] Hospital, [3]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: BCR-ABL tyrosine kinase inhibitors (TKIs) are selective therapies for patients with chronic myeloid leukemia (CML) and induce deep molecular response (DMR). However, many clinical trials of discontinuing TKIs have reported that sustained treatment-free remission (TFR) could only be observed in about 40% of patients for two years. Failure to discontinuation results from the inability of TKIs to eradicate CML leukemia stem cells (CML-LSCs). Among the several factors predict relapse after discontinuation of TKI therapy, only the duration of TKI therapy and DMR closely related to which generation of TKIs was used have been associated with TFR. Furthermore, in our previous observation, 12/22 patients maintained a stable DMR after TKIs withdrawal, and we found patients with second generation TKIs relapsed less than those with Imatinib. Thus we suppose second generation TKIs and Imatinib may have different effects on chronic myeloid leukemia stem cells and affect the outcome of TKIs discontinuation.

Aims: The aim of this study is to investigate how different TKIs affect CML-LSCs in the study of TKIs discontinuation.

Methods: Fresh bone marrow samples were obtained from patients with newly diagnosed chronic phase CML and isolated for CD34+ cells by magnetic cell sorting. Then treated CD34+ cells cultured in growth factors supplemented serum-free medium with Imatinib and Dasatinib for continually three days and stopped for one day. Colony-forming cell (CFC) assays, apoptosis measurement by Annexin-V staining, and cell proliferation detected by WST were performed. Also the three groups of samples were performed proteomic analysis.

Results: After treating CML CD34+ cells with Imatinib and Dasatinib for 72h, then stopped for 24h, the number of CFU in dasatinib group was less than imatinib group, as proliferation. On the contrary, there was much apoptosis in dasatinib group. Proteomic analysis identified 160 upregulated and 151 downregulated proteins differentially expressed between imatinib group and dasatinib group, which marked enriched in mitochondrial oxidative phosphorylation, including NADH dehydrogenase, cytochrome c oxidase and ATP synthase.

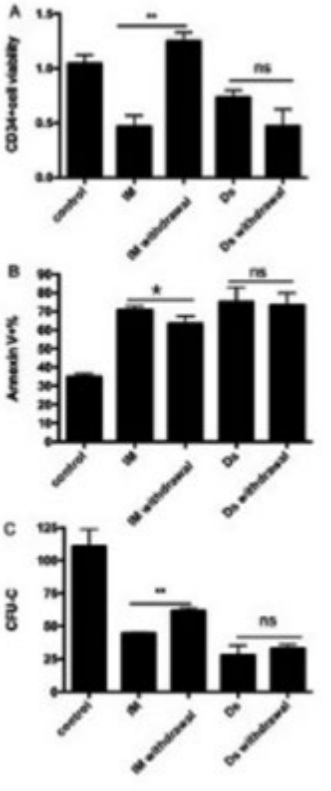

Figure 1.

Summary/Conclusion: We demonstrated that Imatinib and Dasatinib have obviously different effects on CML-LSCs through regulating metabolism process, specifically promoting oxidative phosphorylation to increase proliferation and avoid apoptosis, which may provide new target for eliminating CML-LSCs in the study of successful TKIs discontinuation.

PB1898

DESIGN, SYNTHESIS, ANTI-PROLIFERATIVE, CELL CYCLE INHIBITORY AND IN-VIVO ANTILEUKEMIC ACTIVITY OF NOVEL THIAZOLIDINEDIONES IN COMBINATION WITH IMATINIB

H. Joshi*, R. CS

Pharmaceutical Chemistry, Bharati Vidyapeeth's College of Pharmacy, Navi Mumbai, India

Background: Imatinib, the most affordable and effective tyrosine kinase inhibitor for chronic phase chronic myeloid leukaemia is becoming resistance in many patients. Efforts are being made to combine the imatinib with other molecules to dodge the resistance and to get deeper molecular responses. This concept has been substantiated by recent phase 2 trial of imatinib in combination with well-known thiazolidinedione (TZD), pioglitazone. TZDs like rosiglitazone, pioglitazone once known for their potent antidiabetic action were withdrawn from the market due to their ability to cause cardiotoxicity and bladder cancer respectively and these side effects have been attributed to their full agnostic activity towards peroxisome proliferative activated receptor γ (PPAR γ).
Aims: To circumvent the PPARγ activation and thus toxicity, we design and synthesized novel TZDs (3a-3y) and studied their in-vitro and in-vivo antiproliferative activity in combination with imatinib.
Methods: Synthetic scheme was standardized and molecules 3a-3y were synthesized as per standard scheme. Molecules were characterized using IR, 1H NMR, 13C NMR and mass spectrometry. Antiproliferative activity was carried out using SRB assay on various leukemic cell lines. Moieties were also screened for their toxicity on non-transformed hepatocyte using MTT assay. Cell cycle inhibition assay was carried out using propidium iodide and FACS. Inhibition of proliferative and cell cycle markers, PCNA and cyclin D1 inhibition was checked by western blot analysis. PPARγ activation assay was carried out using ELISA test. In-vivo activity of 3t and 3x in combination with imatinib was carried in mice xenograft model with the permission from institutional ethical committee.
Results: The IR, 1H NMR, 13C NMR and mass spectra data confirmed the structure of molecules. The anti-proliferative activity of molecules was in the range of 0.19-70 µM on k-562 cell line. The MTT assay confirmed the safety of all moieties on untransformed hepatocytes. Molecules bearing significant anti-proliferative activity were also found to arrested the cells in G0/G1 phase in dose and time dependent manner. Two molecules 3t and 3x emerged as a lead entities. Maximum tolerated dose analysis revealed that molecules were tolerated up to 2000 mg/kg. These two lead compounds found to significantly reduce the tumour volume in combination with imatinib.
Summary/Conclusion: In the developing countries like India, Imatinib is the only affordable tyrosine kinase inhibitor (TKI). Compared to 2nd generation TKIs, imatinib is well tolerated and has a proven efficacy. These novel agents when combined with imatinib will help to get deeper responses and overcome resistance to imatinib. Further investigation on leukemic stem cell and long term toxicity of these molecule are under investigation.

PGP AND BCRP INHIBITOR AS A MODULATOR OF IMATINIB RESISTANCE

R.S. Alves[1,2], A.C. Gonçalves[1,2], J. Jorge[1,2], A. Almeida[3,4], A.B. Sarmento-Ribeiro[1,2,5,6,*]

[1]Laboratory of Oncobiology and Hematology, [2]Coimbra Institute for Clinical and Biomedical Research (iCBR)-Group of Environment Genetics and Oncobiology (CIMAGO), Faculty of Medicine, University of Coimbra (FMUC), Coimbra, [3]Hospital da Luz, [4]CEDOC- Chronic Diseases Research Center, Lisboa, [5]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [6]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal

Background: In chronic myeloid leukemia (CML), the most relevant mechanisms associated with the acquisition of resistance to tyrosine kinase inhibitors (TKIs) are those dependent on the therapeutic target, the BCR-ABL oncoprotein. Point mutations and overexpression are the mechanisms take into considerations for therapeutic selection according to guidelines. However, intracellular drug concentration has proved to be very important in therapy response and in the acquisition of drug resistance. Imatinib (IMA), as other TKI, to achieving the intracellular compartment need influx transporters like OCT1 and OCTN2. In opposition, the presence of efflux transporters, like P-gP and BCRP, remove the TKIs from the cell conditioning the achievement of the therapeutic dose. Based on this, the modulation/inhibition of efflux transporters may contribute to the higher efficacy of TKIs.
Aims: The objective of this study was to evaluate the therapeutic potential of Elacridar (P-gP and BCRP inhibitor) in monotherapy and in combination with Imatinib, trying to overcome resistance in *in vitro* models of CML.
Methods: To achieve this goal, we used three CML cell lines: K562 cells (sensitive to Imatinib), K562-RC (8x resistant to IMA) and K562 RD (18x resistant to IMA). P-gP and BCRP activity was evaluated by flow cytometry (FC). The therapeutic potential of Elacridar was assessed in cells incubated in the absence and presence of Elacridar, in monotherapy and in combination with increasing doses of Imatinib, by the resazurin method. Cell death was evaluated by optical microscopy (May-Grünwald-Giemsa staining) and by FC (Annexin V/7-AAD). The *Apoptosis, DNA Damage, and Cell Proliferation* Kit was used to analyze the mechanism of cell death and proliferation. The cell cycle was evaluated by FC (PI/RNAse). The data were analyzed statistically, and the differences were considered significant when $p<0.05$.
Results: Resistant cell lines show higher expression and activity of P-gP and BCRP compared to the sensitive one. Elacridar in monotherapy, in tested concentrations, did not reach the IC_{50} in any cell line. However, the association of 250 nM of Elacridar with Imatinib modulated the resistance and re-sensitized resistant cells to Imatinib. In mechanistic terms, Elacridar in monotherapy induced cell death by apoptosis/necrosis, showing no effect in cell cycle progression. In combination with Imatinib was observed cell death by apoptosis, accompanied by increased caspase-3 activation, cleaved PARP, and DNA damage (phosphorylated H2AX). This effect was accompanied by a cell cycle arrest in S phase.
Summary/Conclusion: In conclusion, our results suggest that Elacridar in therapeutic combination with Imatinib re-sensitize resistant cell lines to Imatinib, namely in cell lines which the main mechanism of drug resistant was associated with efflux transporters. These results, if translated into clinical practice, may contribute to therapy response improvement in patients resistant to Imatinib.
This work was supported by Center of Investigation in Environment, Genetics, and Oncobiology (CIMAGO) and FCT (SFRH/BD/51994/2012).

MYOFIBROBLASTS DERIVED FROM CHRONIC MYELOGENOUS LEUKEMIA PATIENTS EXPRESSED BCR-ABL TRANSCRIPT WHEN CULTURED WITH INTERLEUKIN-1 BETA

N. Shirafuji*, T. Matsuo, R. Sumiyoshi, H. Tashiro

Department of Hematology/Oncology, Teikyo University School of Medicine, Tokyo, Japan

Background: We previously reported that human interleukin 1-beta (IL-1-b) stimulated bone-marrow stromal myofibroblasts to express a hematopoietic molecule CD34. We also reported that a some fraction of myofibroblasts from bone marrow of acute myelogenous leukemia (AML) patients and from chronic myelogenous leukemia (CML) ones showed characteristics of original AML blasts and CML cells, such as chromosomal translocations and the expression of myeloid markers. However, when myofibroblasts were not separated and cultured totally, that is, bulk cultures mixed with normal and leukemic myofibroblasts, leukemia-specific markers were detected in DNA level, but not expressed in RNA levels for a long term cultures.
Aims: We showed in this report that myofibroblasts positive for leukemic markers was dormant and G0 phase in the mixed normal and leukemic myofibroblasts, and when IL-1-beta was added in the cultures, the fusion transcript was observed.
Methods: Bone marrow samples were collected from informed CML patients, which were separated with density centrifugation method. Cells were cultured in DMEM with 20% FCS to prepare myofibroblasts. The obtained myofibroblasts were cultured for one month, and FISH was analyzed with bcr and abl probes. Cells were further cultured in DMEM/F12 medium supplemented with 20% KSR and with recombinant human IL-1-b for one week. The morphological changes and the expression of specific genes were observed.
Results: When bone marrow-derived stromal myofibroblast obtained from CML patients were cultured in an ordinary DMEM with 10% FCS medium, FISH analysis detected 1-5% BCR-ABL fusion chromosome in the cultures; however, RT-PCR analyses revealed that leukemia-specific Bcr-Abl transcript was not detected. When CML-derived myofibroblasts were cultured in DMEM/F12 medium with IL-1-beta for one week, Bcr-Abl transcript was detected with RT-PCR analysis. And, CD41 molecule and GATA-2 transcription factor were also detected in the cultures.
Summary/Conclusion: Serum-free culture with IL-1-beta induced activation of CML-derived myofibroblasts that were dormant in the ordinary culture. In this system hematopoietic progenitor-cells may promote to grow.

Background: The selective targeting of ATP binding pocket in ABL gene by 1st generation tyrosin kinase inhibitor (TKI) imatinib led a huge success in the nearly complete control of chronic myeloid leukemia (CML). However, the inevitable development of resistant mutation bypassing the inhibitory effect of imatinib in CML cells initiated the development of 2nd generation TKI (2G-TKI) of nilotinib and dasatinib. With the introduction of 2G-TKI, the standard frontline treatment of CML is now changed into 2G-TKI.
Aims: We investigated the molecular predictor for the treatment response in patients with newly diagnosed CML and treated with 2nd generation TKI, nilotinib.
Methods: We performed mRNA sequencing (>30M reads) in peripheral blood samples from 12 patients who achieved $MR^{3.0}$ at 6 months (n=3) or not (n=3) and achieved $MR^{2.0}$ at 3 months (n=3) or not (n=3) for candidate gene discovery, and then conducted real-time quantitative PCR (RQ-PCR) for validation in 72 patients who were treated with nilotinib as frontline treatment. Gene expression from follow-up samples at 3 months was also measured.

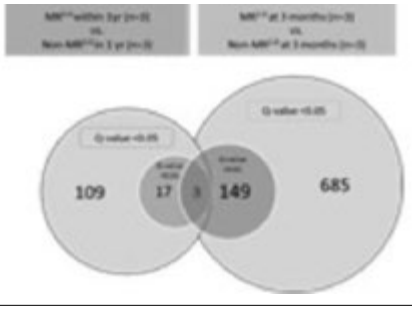

Figure 1.

Results: According to the criteria of fold change >2.0 and q-value<0.01, a total of three genes of AOC1 (Amine oxidase, copper containing 1), BEX1 (The Brain-Expressed X-linked (BEX) 1 gene), and PRSS57(Protease, Serin, 57) were extracted from mRNA-sequencing data as candidate genes for the molecular predictor for the response to nilotinib (Figure 1). The results of RQ-PCR for validation of these 3 genes demonstrated that baseline expression level of AOC1 and PRSS57 were not associated with $MR^{2.0}$ at 3 months (p=0.95 and 0.81, respectively). However, low baseline BEX1 gene expression ($2^{-\Delta Ct}$ X 100<12.09) at baseline was significantly associated with good early molecular response at 3 months. Baseline high BEX1 expression was significantly associated with the reduced cumulative incidence of deep molecular response of $MR^{5.0}$ (HR=0.41, p=0.022), and showed a trend toward the decreased incidence of $MR^{4.5}$ (HR=0.53, p=0.052). BEX1 gene expression was decreased in most cases (84.3%, 59/70 patients), while it was increased in 11 patients. The median change of BEX1 expression ($2^{-\Delta Ct}$ X 100) was -11.9 (range, -286.2 ~ 27.5). However, $MR^{2.0}$ at 3 months since the nilotinib treatment was not associated with the direction of change of BEX1 expression (χ^2=0.54, p=0.46)
Summary/Conclusion: Our study showed that lower BEX1 gene expression can predict early (3 months) molecular response and deep molecular response of $MR^{5.0}$ in newly diagnosed CML treated with nilotinib. Further larger scale confirmatory study is warranted.

HEAT SOCK PROTEIN 90 INHIBITION AS A POTENTIAL THERAPEUTIC TARGET IN CHRONIC MYELOID LEUKEMIA

D. Santos[1], R. Alves[1,2], A.C. Gonçalves[1,2], J. Jorge[1,2], H. Girão[3], S. Catarino[3], J. Barbosa de Melo[2,4], A.B. Sarmento-Ribeiro[1,2,5,6,*]

[1]Laboratory of Oncobiology and Hematology and University of Hematology, [2]Coimbra Institute for Clinical and Biomedical Research (iCBR)-Group of Environment Genetics and Oncobiology (CIMAGO), [3]Coimbra Institute for Clinical and Biomedical Research (iCBR), [4]Cytogenetics and Genomics Laboratory, Faculty of Medicine University of Coimbra, [5]Clinical Hematology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [6]Center for Neuroscience and Cell Biology (CNC), University of Coimbra, Coimbra, Portugal

Background: HSP90 belongs to the heat shock protein family, a functional class of chaperone molecules that are transcriptionally upregulated by heat and other stressors. HSP90 facilitates the maturation, stability, activity, and intracellular folding of more than 200 proteins, called 'client proteins'. In cancer cells, HSP90 helps to overcome multiple environmental stresses, including genomic instability/aneuploidy, proteotoxic stress, increased nutrient demands, reduced oxygen levels, and to prevent destruction by the immune system. One of these client proteins of HSP90 is BCR-ABL, the oncoprotein responsible for Chronic Myeloid Leukemia (CML). Cancer cells that depend on this oncoprotein for survival are sensitive to HSP90 inhibition. Hsp90 inhibitors, by preventing nucleotide-dependent cycling interfere with the chaperone activity of HSP90, resulting in targeting of client proteins to proteasome degradation. Alvespimycin (17-DMAG) is an HSP90 inhibitor that has better pharmacokinetic properties and fewer side-effects compared to others benzoquinone ansamycins.
Aims: This work aims to study the effect of alvespimycin in chronic myeloid leukemia cell lines (sensitive and resistant to imatinib) and to explore the role of HSP family in the sensitivity to imatinib.
Methods: In this context, we used 3 CML cells lines: the K562 cells, sensitive to Imatinib, and the K562-RC and K562-RD cells resistant to Imatinib. Cells were incubated in the absence and presence of increasing concentrations of 17-DMAG (from 1 to 1000 nM), in a single dose. The dose-response curves were determined by resazurin assay. Cell death was determined by microscopy (May-Grunwald Giemsa staining) and by flow cytometry (FC), using Annexin V and Propidium Iodide (PI) double staining. The Apostat Probe was used to evaluate caspase expression levels and JC-1 probe to determine the mitochondrial membrane potential, by FC. Cell cycle was evaluated by FC, using PI/RNase assay. The protein expression levels of HSP family were analyzed by western blot.
Results: Our results showed that 17-DMAG induce a reduction in cell lines viability, with an IC50 of 50 nM for K562 and K562-RD cells and lower than 50 nM for the K562-RC cell line, after 48 hours of treatment. This compound induces cell death predominantly by apoptosis, confirmed by morphological analysis, FC and by the increase of JC-1 Monomers/Aggregates ratio. Furthermore, 17-DMAG induces cell cycle arrests in K562 in G0/G1 phase. The HSP protein analysis showed that K562-RC have slightly increased in HSP90 expression comparing with K562 cells.
Summary/Conclusion: In conclusion, our results suggest that inhibition of HSP90 by alvespimycin (17-DMAG) could be used as a new potential approach in the treatment of CML, even in case of Imatinib resistance.
This work was supported by Center of Investigation in Environment, Genetics, and Oncobiology (CIMAGO).

KILLER IMMUNOGLOBULIN-LIKE RECEPTOR GENOTYPES IN TURKISH PATIENTS WITH ACUTE AND CHRONIC MYELOID LEUKEMIA

M. Erkoç[1], E. Gürkan[2,*], H.D. Dinçyürek[2], S. Dinkçi[3], Ö.G. Öztürk[4], E. Erken[5]

[1]Dept of Internal Medicine, [2]Dept of Hematology, [3]HLA Laboratory, [4]Central Laboratory, [5]Dept of Rheumatology/Immunology, Çukurova University Medical School, Adana, Turkey

Background: It is a well-known fact that natural killer (NK) cells have anti-tumour activities. This activity of NK cells is regulated by specific receptors called KIR (Killer Immunoglobulin-like receptors). The proportion between the activatory and inhibitory receptors, binding strength of receptors to the given ligands and the balance between the composite signals determine the health and ailment attitudes of NK cells. Previous studies have shown decreased expression of HLA class 1 molecules on leukemic cells. It has been postulated that lack of clearance of the leukemia cells could be caused

by the lack of activity of the NK cells, which may be the result of the genetically determined KIR/HLA ligand content.
Aims: In this study we investigated the association of KIR genes with acute (AML) and chronic myeloid leukemia (CML) patients in Turkish population and also tried to correlate with the clinical outcomes.
Methods: Patient group consisted of patients with AML (n=34) (M/F: 31/15); mean age 56 years, and CML (n=46) (M/F: 18/16; mean, 52 years. Age and sex matched 100 healthy controls were also included. DNA from venous blood samples was extracted by DNA isolation kit (QIAGEN Vertriebs GmbH, Vienna, Austria). Genotyping of KIR genes was performed using the multiplex KIRSSO typing kit from Tepnel Lifecodes Corporation (CT, USA). The statistical significances were assessed through Pearson's homogeneity chi-squared test.
Results: The presence of KIR2DL3 was significantly increased in the leukemia patients relative to the controls (91.3% *vs* 78%, OR=0.340, P=0.016). In CML patients, KIR2DL3 gene frequency was significantly higher compared to controls (93.5% *vs* 78.0%, OR=0.247, P=0.031). In addition, presence of KIR2DL2 and KIR2DS2 was significantly decreased in the CML patients compared with controls with the same level of significance (34.8% *vs* 52.0%, OR=2.031, P=0.053). In CML patients who achieved MMR (BCR-ABL1≤0.1% at 12 months of treatment), gene frequency of KIR2DL2 and KIR2DS2 was lower compared to the control group (33.3% *vs* 52.0%, P=0.054, for both analysis); whereas in those without MMR gene frequency was 40%, P>0.05). CML patients without MMR had a higher frequency for KIR2DS1 compared to controls (70.0% *vs* 35.0%, P=0.041) which was 36.11% for those patients with MMR. There were no associations of KIR AA and Bx genotypes between leukemia patients and controls. The genotypic associations for AML patients were not significant.
Summary/Conclusion: KIR2DL2 and KIR2DS2 were suggested in previous studies as being markers for the much more activating haplotype for NK cells. Decreased gene frequencies of KIR2DL2 and KIR2DS2 in CML patients in our study support these findings as such that their reduction would presumably lead to more inhibition with tyrosine kinase inhibitors. Better treatment outcomes observed in this study as reflected by a higher frequency of MMR in patients who had lower KIR2DL2 and KIR2DS2 frequencies suggest that prognostic information could be available by further understanding the role KIR interactions in leukemic patients. In addition our results suggest that increased frequency of a weak inhibitory receptor KIR2DL3 in leukemic patients might contribute decreased NK cell activity against leukemia cells.

PB1904

THE ROLE OF LEUKEMIC STEM CELLS AND EARLY PROGENITOR CELLS IN CHRONIC MYELOGENOUS LEUKEMIA RECURRENCE AFTER THE DISCONTINUATION OF TREATMENT WITH TKI

T. Perekhrestenko[1,*], I. Sviezhentseva[2], D. Bilko[2], G. Starodub[1], D. Irina[3]

[1]Blood disease, State Institution «Institute of Hematology and Transfusiology of NAMS of Ukraine», [2]The Center of Molecular And Cell Research, The National University of Kyiv Mohyla Academy, [3]Hematology department, State Institution "National Research Center for Radiation Medicine of NAMS of Ukraine", Kyiv, Ukraine

Background: Leukemic stem cells (LSCs) and myeloid progenitor cells are believed to play an important role in the pathogenesis of chronic myeloid leukemia (CML). LSCs are able to remain at hemopoietic niches for a long time, remaining insensitive to TKI. It is very difficult to identify using cytogenetic and molecular diagnostic methods. Therefore, in a long-term remission, after the discontinuation of the TKI therapy, LSCs can cause relapse of CML in patients' bone marrow.
Aims: The aim of our study is to compare the proliferative activity of hemopoietic stem and progenitor cells of patients with CML who had a long-term remission as a result of TKI treatment.
Methods: We studied bone marrow samples of 17 patients with CML who had a long-term remission as a result of the TKI therapy. Experiments were conducted *in vitro*, with a use of liquid culture. In order to accumulate the bone marrow stem cells, patients' hemopoetic cells were cultivated for 28 days with bone marrow stromal cells in DMEM culture medium (SIGMA, USA) with addition of 10% fetal calf serum (SIGMA, USA). Subsequently, patients' hemopoietic stem cells were cultivated in a liquid culture *in vitro* in RPMI medium (SIGMA, USA) with an addition of a granulocyte-macrophage colony stimulating factor (SIGMA, USA) and a 20% fetal calf serum. We counted the number of cells in the liquid culture using a Goriaev's chamber. We also prepared hematopoietic cell samples after cultivation, using cytocentrifuge. We stained samples using Pappenheim method and counted different hemopoetic cells under a microscope. We compared the results of cultivation with the presence of CML remission in patients after 6 months of discontinuation of TKI.
Results: After cultivation of patient's bone marrow cells in a liquid culture *in vitro* solely with bone marrow stromal cells, there was a small number of hematopoietic precursor cells (15-37,000 per ml) on 28th day of cultivation. Following the cultivation, these cells were removed and cultivated with an addition of the granulocyte-macrophage colony stimulating factor. The results showed that in patients who had CML relapse six months after the discontinuation of the TKI therapy, the proliferative activity of hemopoietic progenitor cells increased by 17%, compared to Patients who had a stable remission as a result of a TKI therapy. In addition, patients' with unstable remission as a result of TKI therapy showed the prevalence of early forms of cells of the granulocyte-macrophage series (blast cells, promyelocytes and myelocytes).
Summary/Conclusion: Consequently, long-term cultivation with stromal cells allows to accumulate the stem cells and the early progenitor bone marrow cells from patients with CML. LSCs seem to be the reason of CML relapses when the TKI therapy is discontinued. They remain in a state of rest for a long time, and are able to restore the leukemia clone under favorable conditions.

LW-213 TRIGGERED G2/M CELL CYCLE ARREST AND APOPTOSIS OF CHRONIC MYELOGENOUS LEUKEMIA CELLS THROUGH SUPPRESSION OF CDK9-RELATED SIGNALING PATHWAYS

J. Xu*, H. Hui

State Key Laboratory of Natural Medicines, China Pharmaceutical University, Nanjing, China

Background: LW-213, a derivative of wogonin derived from traditional Chinese medicine plant *Scutellaria baicalensis Georgi*, has been shown anticancer activities on several breast cancer cell lines and xenograft models. Our previous results have reported the anti-leukemia effects of wogonin while the therapeutic effect of LW-213 in chronic myelogenous leukemia (CML) has been barely known.
Aims: To clarify whether LW-213 has better inhibitory effect on CML and its possible mechanism.
Methods: we explore the potency of this compound on K562, imatinib-resistant K562, and primary CML cells.
Results: These results showed that LW-213 inhibited proliferation of CML cells and induced cell cycle arrest in G_2/M phase, leading to cell apoptosis. Meanwhile, LW-213 down-regulated cyclin dependent kinase 9 (CDK9) and inhibited phosphorylation of Stat3, down-regulating Mcl-1and cyclin B1. All results suggest that LW-213 triggered G2/M cell cycle arrest and apoptosis through the suppression of CDK9-related signaling pathways. In vivo, LW-213 prolonged survival of NOD/SCID mice inoculated with primary CML cells without any organ toxicity.
Summary/Conclusion: In conclusion, LW-213 might be a potential candidate compound on clinical treatment in imatinib-resistant CML patients.

PB1906

A MATHEMATICAL APPROACH TOWARDS IMMUNOLOGICAL CONTROL OF MINIMAL RESIDUAL DISEASE IN CML PATIENTS

I. Roeder[1,2], A.C. Fassoni[3], T. Haehnel[1], C. Baldow[1], I. Glauche[1,*]

[1]Institute for Medical Informatics and Biometry, Faculty of Medicine, Technische Universität Dresden, [2]Data and Trial Management Unit, National Center for Tumor Diseases (NCT), Partner Site Dresden, Dresden, Germany, [3]Instituto de Matemática e Computação, Universidade Federal de Itajubá, Itajubá, Brazil

Background: There is increasing evidence in patients with Chronic Myeloid Leukemia (CML) pointing to the role of the immune system in the sustained control of residual leukemic cells after tyrosine-kinase inhibitors (TKI) treatment cessation. It has been speculated that, once the treatment has reduced the leukemic cell burden below a certain threshold, the immune cells are capable to control the disease, or even to completely eliminate the leukemic clone. However, at the moment these mechanisms are poorly understood.
Aims: It is our aim to contribute to a quantitative, mechanistic understanding of the immune response in TKI-treated CML. Specifically, we address the questions if and why the immune response appears to be effective only at a low level of leukemic cells. Here it is of particular interest to understand the interaction of two dynamic processes: (i) the stimulation of immune cells by the presence of leukemic cells and (ii) the immune system-mediated elimination of these cells.
Methods: We developed a mathematical framework describing CML progression and treatment in terms of ordinary differential equations. Within

this model framework we consider different assumptions about the mechanisms (i) by which immune cells are stimulated by leukemic cells and (ii) of how leukemic cells are targeted by immune cells. The combination of the different assumptions leads to several structurally different models, which are characterized by different systems dynamics (such as unavoidable relapse, low-level control of leukemic cells, potential cure, etc.).
Results: We compare our conceptual results with available data sets on the BCR-ABL1 levels from CML patients after TKI cessation, thereby allowing us to assess and critically discuss the plausibility of the particular assumptions. Specifically, we show that both the recruitment of specific immune cells as well as the immune response-related kill of leukemic cells need to be determined by non-constant and even non-linear regulation processes to consistently explain clinically observed outcomes after TKI cessation, as there are, early molecular relapse, fluctuating but extremely low BCR-ABL1 levels, and long-term BCR-ABL1 negativity.
Summary/Conclusion: The model analyses suggest that the shape of the dose-response relationship of leukemic cell burden and immune response is essential to understand and predict the molecular relapse dynamics after TKI cessation. To identify these relationships, one needs to *define* relevant readouts of immune response and to *quantify* these over time and in relation to the tumor load. Our results highlight the necessity to understand the mechanisms of immune control in leukemia therapy to employ this effect for optimal treatment results and to identify clinical measures that allow to derive better predictions about the outcome of treatment cessation.

AVOIDING BCR/ABL EXPRESSION IN CHRONIC MYELOID LEUKEMIA CELLS BY CRISPR/CAS9 SYSTEM GENOME EDITION TOOL.

V. Alonso-Pérez[1,*], M. Herrero-García[2], L. Méndez-Sánchez[2], E. Vuelta[2], M. Abáigar[3], A. Montaño-Brioso[3], A. Marin-Quilez[1], M. Quijada-Álamo[1], J.L. Ordóñez[1], F. Sánchez-Guijo[4], J.M. Hernández-Rivas[1], M. Sánchez-Martín[2], I. García-Tunón Llanio[1]

[1]Molecular genetics in onco-hematology Research Group, Institute for Biomedical Research of University of Salamanca (IBSAL)-University of Salamanca, [2]Servicio de Transgénesis, Nucleus, Universidad de Salamanca, [3]Institute for Biomedical Research of University of Salamanca (IBSAL)-University of Salamanca, Salamanca, Spain, [4]Hematology Department, Institute for Biomedical Research of University of Salamanca (IBSAL)-University of Salamanca, Salamanca, Spain

Background: CML is a disorder driven by hematopoietic stem cells that acquire the t(9;22)(q34;q11) traslocation resulting in the expression of the BCR-ABL oncogenic fusion protein, which increase cell survival, proliferation and induces an aberrant myeloid commitment. CML treatments are predominantly based on the use of tyrosine kinase inhibitors (TKI). However, CML eradication is still hindered by the emergence of TKI resistant cells. A definitive and effective therapeutic strategy is therefore still needed for these patients. Few studies have used genome edition CRISPR-based techniques to eliminate fusion oncogenes generated by chromosome translocations. BCR-ABL fusion is an ideal therapeutic target to be eliminated at the genomic level by using these new genome edition tools. We demonstrate that CRISPR/Cas9 system efficiently disrupts, at a genomic level, the BCR-ABLp210 gene fusion in an *in vitro* model of human BCR-ABL, avoiding its oncological effects.
Aims: To evaluate the ability of CRISPR/Cas9 technology to induce frameshift mutations on the BCR/ABL sequence avoiding its expression in K562 cell line.
Methods: The K562 cell line derived from a chronic myeloid leukemia (CML) patient and expressing B3A2 BCR-ABL fusion gene, is known to be particularly resistant to apoptotic cell death. Through CRISPR/Cas9-mediated genomic edition, we set to edit the coding sequence of BCR-ABL in K562 cells, inducing indels that modify the oncogene ORF, and therefore, the protein expression. We designed 3 sgRNAs against tyrosine kinase domain sequence of ABL1 and were introduced in a plasmid containing the Cas9 nuclease coding sequence. K562 cells were electroporated with the mix of sgRNAs. The genetic edition on ABL1 tyrosine kinase domain sequence was checked by PCR and Sanger sequencing. The BCR/ABL expression was analyzed by qPCR. To assess the edited cells viability and apoptosis, flow cytometry, measuring Annexin V staining and DNA content was used.
Results: We achieved to edit the coding sequence of BCR-ABL in K562 cells by CRISPR/Cas9 system, inducing mutations that modified the oncogene ORF. We found a 100 bp recurrent induced deletion in the sequence corresponding to the TK domain of ABL1. This deletion leads to a premature stop codon, which prevents the correct translation of the protein. As a result of this deletion, the edited K562 cells showed a decreased expression of ABL1, higher levels of apoptosis and an altered expression of downstream ABL1 targets, proof of lack of expression of the BCR-ABL oncoprotein.
Summary/Conclusion: We demonstrate the ability of CRISPR/Cas9 system to disrupt at genomic level, the coding sequence of BCR/ABL fusion oncogene resulting from translocation t (9;22) in established cell lines derived from patients of CML, avoiding its oncological effects. The use of CRISPR-Cas9 technology could be a promising new therapeutic option for CML patients who have developed TKI resistances. Bone marrow CML leukemic stem cells could be *ex vivo* edited by CRISPR-Cas9 technology and specifically selected to transplantation treatment.

PB1908

OUTCOME OF FRONTLINE TREATMENT WITH GENERIC OF IMATINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

S. Menif*, N. Ben Romdhane, Z. Manai, H. Ghedira, S. Zriba, F. Msaddek

Hematology, Pasteur Institut, Tunis, Tunisia

Background: The development of oral well tolerated bcr-abl tyrosine kinase inhibitor (TKI) has revolutionized the treatment of chronic myeloid leukemia (CML) and allowed thousands of patients over the past 15 years to live healthy and productive. Generic imatinib is already available in a number of countries, the use of generic is expected to lower the cost of CML therapy however the data regarding their efficacy and tolerability in larger populations of CML patients are lacking. In January 2015 Health Tunisia approved CEMIVIL, a generic of imatinib, manufactured by HIKMA Pharmaceutical.
Aims: The aim of this study was to evaluate the efficacy and tolerability of imatinib generic in Tunisian patients suffering from chronic phase CML.
Methods: In this retrospective analysis data from patients with frontline cemivil between January 2015 and December 2017 is included .we report the rate of bcr-abl/abl reduction to<10% at 3 months and to<1% at 6 months of therapy, the rate of optimal response and failure according to current ELN guidelines, the rate of MMR, MR4 and MR4.5 achieved at 12 months of therapy and the rate of patients switched to second generation TKI have been assessed.
Results: Between January 2015 and December 2017, 51 patients started do novo treatment with generic. Early molecular remission defined by bcr-abl/abl ratio <10% at 3 months was achieved in 83%, bcr-abl/abl ratio <1% at 6 months in 89% of patients. At 12 months of therapy 13 patients (25%) achieved RM^4 and 5 patients (9%) achieved $RM^{4.5}$. 14 Patients (27%) have been switched to second generation TKI, 2 patients due to intolerance, 8 patients due to resistance and 4 patients due to progression.
Summary/Conclusion: The findings of the present study showed comparable efficacy and safety of Cemivil in the treatment of patients with CML. The arrival of generic imatinib at a reduced price has the potential to markedly impact the cost of care for CML. It may also increase the access of patients to this remarkable drug that has previously been unaffordable to some.

MTORC2 COMPLEX SUSTAINS LEUKEMIC STEM CELL SELF-RENEWAL BY NUCLEAR RELOCALIZATION OF ITS COMPONENTS

C. Panuzzo*, L. Prioni, J. Petiti, V. Rosso, G. Carrà, C. Calabrese, E. Signorino, E. Bracco, D. Cilloni, A. Morotti

San Luigi Hospital, Orbassano, Italy

Background: The effect of hypoxia on protein translation is mediated in part through inhibition of mammalian target of rapamycin complex 1 (mTORC1), but the principle mechanism for hypoxia-induced mTORC1 inhibition however was not elucidated until recently.
Aims: In order to elucidate leukemic stem cell behaviour including self-renewal, apoptosis, proliferation and molecular pathway involved in these mechanisms we analysed K562 under hypoxic condition. We focused our studies on mTOR pathaway, expecially on mTORC2, which ability to activate directly AKT by Ser473 phosphorylation makes it an interestly candidate in cell self-renewal scenario.
Methods: K562 erythroleukemia cells were maintained in RPMI 1640, supplemented with 10%FCS. Hypoxia exposure was performed by incubation in 5% CO2, 1% Oxygen, 94% N2 condition for different time point (20 and 40 hours). Cell viability and death were performed by MTT assay and Annexin V identification by FACS analysis. Total cell lyses, nuclear and cytoplasm fractions were used to carry out western blot to analyse mTORC1 and mTORC2 pathway and to investigate cellular delocalization of TOR component in hypoxia condition. Immunofluorescence were performed on K562 slices after permeabilization and subsequent primary and FITC-secondary antibody incubation to detect mTOR component localization. RNA

were extract by TRIzol method and used to analyse genes known to be involved in hypoxia pathway.
Results: In agreement with previous works, the hypoxic culture of k562 led to decreased in proliferation and increased in CD34 expression, suggesting the ability of cell line to take a "stem phenotype" under hypoxic condition. Moreover we have observed a reduction of the S phase of the cellluar cycle, and subsequent accumulation on G2/M phase. We observed that after hypoxia exposition mTORC1 pathway is strongly abrogated, as documented by reduction in 4EBP, ribosomal protein S6 and mTOR phosphorylation. Conversely mTORC2 resulted significantly activated, with increased in AKT (ser473), NDRG and SGK phosphorylation, reduction in GSK phosphorilation and increased in total Rac protein. This phenomenon is accompanied by a strong and significant relocation of mTOR, Rictor and Akt in the nucleus. Interesting these peculiar localization has been observed by immunofluorescence on CD34+ CML cells suggesting therefore that it could be a typical behaviour of cells localizing in hypoxic environment. The quantitative analysis on different hypoxic treatments showed a significant increase in VEGF (known to be regulated by HIF1) and SOX genes (SOX2 and SOX17) which would appear to be negatively regulated by mTORC1. Furthermore the computational analysis on HIF promoter showed the presence of many HMG-box motifs, typical of SOX genes, suggesting a possible link between mTORC1 inactivation, mTORC2 and AKT nuclear activation and HIF expression in hypoxic K562 cells.
Summary/Conclusion: We observed that hypoxic treatment leads to a strong mTORC1 decreased activity, inhibits proliferation and promotes survival and stem cell phenotype in K562, with an increased in mTORC2 activity and its relocalization in nucleus. How Rictor and mTORC2 complex act in nucleus is still unknown. A recent work performed on S. Pombae showed that Rictor is able to rilocalize in nucleus by direct link to AKT and E2F transcription factor, favouring its transcription activiy. Our future propose will be to investigate the role of E2F, which have emerged as essential regulators of stem cell fate control in a number of lineages, in maintaining leukaemia stem cells.

PB1910

NILOTINIB *VS* IMATINIB IN ALBANIAN PATIENTS WITH NEWLY DIAGNOSED CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE

A. Cili*, P. Xhumari, P. Pulluqi, T. Caja, E. Calliku, A. Perolla, A. Ivanaj

Hematology, Central University Hospital Mother Tereza, Tirana, Albania

Background: The superior efficacy of nilotinib over imatinib as frontline therapy for CML-CP was first demonstrated in the international phase 3 study Evaluating Nilotinib Efficacy and Safety in Clinical Trials–Newly Diagnosed Patients (ENESTnd).
Aims: Because the efficacy and safety of TKIs may vary depending on ethnic background or genetic factors, focused investigations within well-defined patient populations are crucial in order to better understand the relative benefits and risks of each treatment option for individual patients. We did conduct this study in Albanian patients with newly diagnosed chronic myeloid leukemia in chronic phase
Methods: Adult patients of Albanian ethnicity with Ph+ CML-CP within 6 months of diagnosis and with an Eastern Cooperative Oncology Group performance status ≤2 were eligible. Patients were randomized 1:1 to nilotinib 300 mg twice daily or imatinib 400 mg once daily.The study was conducted according to the ethical principles of the Declaration of Helsinki
Results: Treatment with a tyrosine kinase inhibitor (TKI) targeting BCR-ABL1 is currently the standard of care for patients with chronic myeloid leukemia (CML) in chronic phase (CML-CP). A total of 121 patients were randomized (nilotinib, n=61; imatinib, n=60) from May of 2011 to August 2014 at Hematology clinic ,University Hospital Center "Mother Teresa". In this study, we present the results of a 48 months follow-up data of a study that was conducted to investigate nilotinib 300 mg twice daily *vs* imatinib 400 mg once daily in Albanian population. This study met its primary end point with a statistically significant higher rate of major molecular response (MMR; BCR-ABL1 ≤0.1% on the International Scale) at 12 months in the nilotinib arm *vs* the imatinib arm (50.2% *vs* 26.3; *P*<.0001), and MMR rates remained higher with nilotinib *vs* imatinib throughout the follow-up period.. Estimated 60 months rates of freedom from progression to AP/BC on study were significantly higher on nilotinib (95.1% [*P*=.0497] compared with imatinib (91.2%).
Summary/Conclusion: For the first time we are presenting a geographical distribution of CML patients in Albania. In conclusion, rates of MMR at 12 months were superior with nilotinib *vs* imatinib in Albanian patients with newly diagnosed Ph+ CML-CP. These results suggest that treatment with frontline nilotinib may allow more patients with Ph+ CML-CP to achieve early, deep molecular responses and attain improved long-term outcomes. Estimated rates of 5-year OR on study were 96.7%, and 93.3% for nilotinib 300 mg twice daily and imatinib 400 mg once daily. The safety profiles of both drugs were similar to those from previous studies e international phase 3 study Evaluating Nilotinib Efficacy and Safety in Clinical Trials–Newly Diagnosed Patients (ENESTnd). Because the efficacy and safety of TKIs may vary depending on ethnic background or genetic factors, focused investigations within well-defined patient populations are crucial in order to better understand the relative benefits and risks of each treatment option for individual patients. We did conduct this study in Albanian patients with newly diagnosed chronic myeloid leukemia in chronic phase

LONG-TERM OUTCOMES OF EARLY CP CML PATIENTS WHO HAVE ACHIEVED CCYR BUT NOT MMR AFTER 24 MONTHS ON FRONTLINE IMATINIB THERAPY

S.-H. Kim[1,*], S.-Y. Choi[2], S.-E. Lee[3], W.-S. Lee[4], Y.R. Do[5], J.-Y. Kwak[6], S. Oh[7], J.-A. Kim[8], D.Y. Zang[9], D.-W. Kim[10]

[1]Internal Medicine, Dong-A University College of Medicine, Busan, [2]Leukemia Research Institute, The Catholic University of Korea, [3]Hematology, Seoul St. Mary's Hosipital, Seoul, [4]Internal Medicine, Inje University Busan Paik Hospital, Busan, [5]Hematology-Oncology, Keimyung University, Daegu, [6]Hematology-Oncology, Chonbuk National Universtiy Medical School, Jeonju, [7]Internal Medicine, Kangbuk Samsung Hospital, Seoul, [8]Hematology, St. Vincent's Hospital, Suwon, [9]Internal Medicine, Hallym University Hospital, Anyang, [10]Hematology, Leukemia Research Institute, Seoul St. Mary's Hospital, Seoul, Korea, Republic Of

Background: The BCR-ABL1 tyrosine kinase inhibitors (TKIs) became standard therapy for chronic phase (CP) chronic myeloid leukemia (CML) since imatinib mesylate (IM) was approved as frontline therapy. Complete cytogenetic response (CCyR) has been established as a predictor for disease outcome by the International Randomized Study of Interferon and STI571 (IRIS), and based on many clinical studies. The National Comprehensive Cancer Network (NCCN) and the European Leukemia Net (ELN) have established treatment guidelines that include molecular response milestones. Although failure to achieve these milestones means that switching to a different TKI is needed to limit the risk of progression and death, there is insufficient data to show long-term outcomes in the patients who were in a molecular failure after 24 months (CCyR but not MMR).
Aims: The aim of this study was to evaluate long-term survival end points and identify predictive factors for an achievement of overall major molecular response (MMR) in the patients who have achieved CCyR but not MMR after 24 months on frontline IM therapy, as additional information to guide clinical decisions on selecting patients.
Methods: Among 604 newly diagnosed CP CML patients who received IM for at least 2 years with no prior treatment, 288 (47.7%) patients achieved CCyR but not MMR after 24 months on frontline IM therapy. Finally, to evaluate molecular responses, 280 patients with transcript type of b2a2 and b3a2 were included in this analysis. All qRT-PCR were tested with at least 4.5-log sensitivity in a single laboratory (Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea).
Results: 280 newly diagnosed CP CML patients (including 190 men and 90 women) were evaluated. With a median age of 38.1 years (range, 5-77 years), the distribution of low, intermediate, and high Sokal risk scores were 22%, 35% and 43%, respectively, excluding 30 patients with unknown risk. With a median follow-up of 134.2 months (range, 25.6–195.0 months), 163(58%) patients continued IM and maintained at least a complete cytogenetic response (CCyR), while 117 patients permanently discontinued IM due to intolerance (n=31), warnings according to ELN 2013 recommendations with adverse events (n=43), and treatment failure (n=17), progression (n=9), death (n=1), enrollment of treatment-free remission (TFR) study (n=10), and others (n=6). Among them, 98 (84%) switched to second-generation tyrosine kinase inhibitors (2G TKIs). The CI rates of MMR by 3, 4, and 5 years were 27.9±2.8%, 53.6±3.3%, and 71.8±3.0%, respectively, and the CI rates of CMR by 3, 4, and 5 years were 1.9±0.8%, 5.0±1.4%, and 10.8±2.1%, respectively. The 10-year FFS, PFS, and OS were 89.3±2.2%, 96.0±1.3%, and 98.5±0.9%, respectively. The patients with transcript type of b3a2, compared to b2a2 (RR of 0.22, *P*=0.001) and high Sokal risk, compared to low Sokal risk (RR of 0.67, *P*=0.040) showed a lower rate of overall MMR achievement on IM therapy.
Summary/Conclusion: This study demonstrated long-term survival outcomes in the patients who have achieved CCyR but not MMR after 24 months on frontline IM therapy. In addition, we identify the factors related to an achievement of overall MMR. It provides additional information to guide clinical decisions on selecting high-risk patients. Based on our findings, clinical investigations considering what the treatment goals are, overall survival with a low risk of toxicity or achieving of a deeper molecular response with a hope for TFR, are needed.

PB1912

COMORBIDITY INDEX RELATED OUTCOME IN CHRONIC MYELOID LEUKEMIA PATIENTS

I. Cojbasic[1,2,*], L. Macukanovic-Golubovic[1,2], M. Vucic[1,2]

[1]Faculty of Medicine, University of Nis, [2]Clinic of Hematology and Clinical Immunology, Clinical Center Nis, Serbia, Nis, Serbia

Background: Recent studies have indicated that comorbidity may impact the treatment response and survival of chronic myeloid leukemia (CML) patients treated with tyrosine inhibitors (TKIs). The Charlson Comorbidity Index (CCI) was originally introduced as a tool to measure the influence of relevant comorbid diseases in terms of reduced life expectancies. The score is well established and validated and it is widely used for both hospitalized patients and outpatients.
Aims: The objective of this study was to evaluate the influence of baseline comorbidities on treatment response rate and survival in patients with CML.
Methods: We reviewed the records of patients with newly diagnosed CML between 2006 and 2018, who were receiving imatinib as first line and nilotinib as second line therapy. For this retrospective analysis, patients were divided into two groups with none (CCI 2) or one and more present comorbid conditions (CCI ≥3). The CCI has been used to evaluate concomitant underlying disease at diagnosis as the most extensively studied comorbidity index. Complete cytogenetic response (CCyR) and major molecular response (MMR) have been defined according to the European LeukemiaNet criteria. Overall survival (OS) was calculated from the date of imatinib initiation until death at any time and for any reason.
Results: At the time of analysis, 106 patients could be analysed, of which 57 (53.8%) were female, with median age of 56.4 (18-78) years at imatinib initiation. According to the Euro score, 51.9% patients were classified as low risk, 38.7% as intermediate risk and 9.4% as high risk. EUTOS score was low for 83% of patients. Median follow-up time was 71.5 (6-132) months, and 45 (42.5%) patients had documented comorbidities, 30 (28.3%) with CCI relevant diseases. The distribution of CCI comorbidity risk categories were: diabetes mellitus (n=9), chronic pulmonary disease (n=5), moderate to severe renal insufficiency (n=4), cerebrovascular disease (n=3), peripheral vascular disease (n=3), myocardial infarction (n=2), congestive heart failure (n=2) and peptic ulcer (n=2). The most common comorbidities not considered with the CCI were: arterial hypertension (n=6), angina pectoris (n=3), arrhythmia (n=2), thyroid disfunction (n=2), etc. At 5 years, cumulative incidence of achieving CCyR according to the CCI was similar in both analysed groups: 84.9% in CCI 2 and 78.3% in CCI ≥3. Likewise, no differences in cumulative incidence of MMR has been observed between patients in different CCI groups: 75.5% in CCI2 and 68.9% in CCI≥3. Median time to optimal response for patients with CCI2 or CCI≥3 did not differ within each arm, for CCyR 10.5 *vs* 11.8 months and for MMR 18.3 *vs* 19.1 months. However, it was found that patients with comorbidities had significantly shorter OS. Probabilities of OS at 5 years for patients with CCI2 and CCI≥3 were 92.1% (95%CI: 89.5%>95.3%) and 68.9% (95%CI: 62.8%>72.7%), respectively. There were 18 patients in both groups who died during the follow-up, of which 10 patients died due to non-CML related causes while 8 deaths were resulting from progression of CML.
Summary/Conclusion: This study indicated that in CML patients' comorbidities do not affect achievement of therapeutic response, since the possibility of achieving CCyR and MMR was similar regardless of presence or absence of comorbidity. However, comorbidities have significant negative impact on overall survival, as CML patients' survival is influenced more by comorbidities than by CML itself.

[10]Department of Internal Medicine, Alto Vicentino Hospital, Santorso (Vicenza), Italy

Background: Imatinib is the most commonly used drug in chronic myeloid leukemia (CML) patients (pts) worldwide. In early 2017 a generic formulation was introduced in Italy and CML pts have switched from branded (*i.e.* Glivec®, Novartis) to generic imatinib upon requirement of regional health authorities. Since the use of generic drugs represents a novelty in cancer field, some concerns exist about efficacy and safety in comparison to their originators.
Aims: To analyze the outcome of CML pts switched from branded to generic imatinib for changes in adverse event (AE) profile or efficacy.
Methods: We analyzed a cohort of 294 chronic phase CML pts treated in 10 hematological centers with branded imatinib for at least 6 consecutive months before switching to a generic formulation. After switching, RQ-PCR and biochemical exams were performed at least every 3 months and the assessment of AE was continuously performed. Molecular responses were defined according to the ELN2013 recommendations. The severity of AE was assessed according to the CTCAE 4.0 scale.
Results: Median age at diagnosis was 57 years (range 19-87 years). Sokal score was L/I/H in 162 (55%), 93 (32%) and 24 (8%) pts, respectively (15 cases were not evaluable). Median duration of branded imatinib treatment was 7.4 years (range 0.5-16.7 years). Imatinib dose at switch was 400 mg, less than 400 mg and more than 400 mg daily in 71%, 27%, and 2% of pts, respectively. Imatinib dose was not changed at the time of switch. The majority of pts (171/294, 58%) had experienced at least one AE while on branded imatinib, most commonly muscle cramps, fluid retention, diarrhea and anemia (table). Grade 3-4 non hematological AE were uncommon and included infections (n=4), arrhythmia (n=2) ischemic stroke (n=1) and cardiac failure (n=1). Of note, 9 pts had a secondary neoplasm diagnosed while on branded imatinib. At the time of switch molecular responses were as follows: less than MR3 in 25 (8%), MR3 in 75 (26%), MR4 in 87 (30%) and MR4.5 or better in 107 (36%) pts. At a median follow-up of 7.5 months after switch to generic imatinib (range 0-12.2 months), 49 pts (17%) reported new or worsening AE (table), most commonly nausea, diarrhea and muscle cramps. Grade 3-4 non hematological AE included increase of lipase (n=3), infections (n=2), vomiting (n=1), muscle pain (n=1), and severe allergic reaction at the first intake of generic imatinib (n=1). Twelve pts (4%) interrupted generic imatinib for >30 days and 20 pts (7%) had the dose permanently reduced, most commonly to 200 mg daily. Twenty-two pts (7.5%) discontinued generic imatinib treatment for intolerance (n=9), treatment-free remission attempt (n=8), lack of molecular response (n=3) and death (n=2, both unrelated to CML). Overall, 6 pts (2% of the whole population) switched back to branded imatinib, with improvement in the AE profile, and 4 pts moved to bosutinib (n=3) or nilotinib (n=1). The efficacy of switch was evaluable in 282 pts. Molecular responses remained the same in 229 pts (81%), improved in 37 pts (13%) (from less than MR3 to MR3 or better: n=13; from MR3 to MR4 or better: n=24) and worsened in 16 pts (6%) (from MR3 to less than MR3: n=3; from MR4 or MR4.5 to MR3: n=13).

Table 1.

Table. Frequency of adverse events upon treatment with branded and generic imatinib

Adverse event term	Branded imatinib	Generic imatinib *persistant AE* (severity unchanged from branded imatinib)	Generic imatinib *new or worsened AE* (severity increased from branded imatinib)
Fluid retention	58 (19.7%)	8 (2.7%)	5 (1.7%)
Muscle cramps	71 (24.1%)	23 (7.8%)	9 (3.1%)
Arthralgia	28 (9.5%)	8 (2.7%)	6 (2.0%)
Ocular symptoms	31 (10.5%)	6 (2.0%)	6 (2.0%)
Skin rash / pruritus	24 (8.2%)	6 (2.0%)	3 (1.0%)
Nausea / vomiting	24 (8.2%)	5 (1.7%)	7 (2.4%)
Diarrhea	46 (15.6%)	5 (1.7%)	10 (3.4%)
Increased creatinine	10 (3.8%)	7 (2.4%)	1 (0.3%)
Anemia	37 (12.6%)	14 (4.8%)	4 (1.3%)
Leukopenia	18 (6.1%)	5 (1.7%)	3 (1.0%)
Thrombocytopenia	25 (8.5%)	7 (2.4%)	1 (0.3%)
Overall*	**171 (58.2%)**	**64 (21.8%)**	**49 (16.7%)**

* this value is not the sum of the column since a patient may have experienced more than one AE

Summary/Conclusion: Switch to generic imatinib for pts who have been receiving branded imatinib for at least 6 months appears to be effective and safe. Molecular responses may continue to improve over time. Some pts experienced new or worsened AE but in our cohort only 3.4% of pts needed to switch back to branded imatinib or move to other TKIs.

PB1914

THE SIGNIFICANCE OF VERY EARLY MOLECULAR RESPONSE WITH FRONTLINE DASATINIB TREATMENT IN CHRONIC MYELOID LEUKEMIA PATIENTS AS A STRONG PREDICTOR OF LONG-TERM OUTCOME: FINAL ANALYSIS OF PCR-DEPTH STUDY

Background: In BCR-ABL1 tyrosine kinase inhibitor (TKI) treated chronic phase chronic myeloid leukemia (CP-CML), early molecular response (EMR) at 3 months is currently identified as being one of the most important prognostic factors. Sokal risk score and dose intensity during first 3 months were strongly associated with achievement of EMR. As dasatinib is a novel, oral tyrosine kinase inhibitor with improved potency, identification of very early molecular response (VEMR) would be beneficial.
Aims: We evaluated the possibility of the VEMR at 1 month predicting long-term outcomes in newly diagnosed CP-CML patients treated with dasatinib.
Methods: In this multi-center, observational, open-label study, 102 patients with CP-CML were enrolled to receive dasatinib at a dose of 100 mg once daily. The primary end point was complete molecular response (CMR) by 18 months. Secondary end points including molecular response (MR) by 1, 3, 6, 12, 18, 24, 36 months, time to and duration of MMR and CMR, and safety were tested. A receiver operating characteristic (ROC) curve from BCR-ABL1 transcript level on Day+28 was calculated to predict EMR and MMR at specific timepoints.
Results: Median age was 49 years (19-81 years) and 61 patients were male. With median follow-up duration of 33.6 months (0.9-38.6 months), 71 (69.6%) out of 102 patients were still on dasatinib treatment and 31 patients discontinued due to disease progression (n=2) or treatment failure (n=3) or adverse events (n=18) or other reasons (n=8). The BCR-ABL1 mutations, assessed in 10 patients after dasatinib discontinuation, were detected in 3 patients which were all T315I mutation. The cumulative CMR by 18 months and MMR by 36 months were 20.5% and 84.8% respectively. In safety analyses, grade 3/4 thrombocytopenia (30.3%) was most common. Pleural effusion occurred in sixteen (15.6%) patients which were mostly grade 1/2. The cut-off value of BCR-ABL1 transcript on Day+28 was 40% by ROC curve analysis. Among 95 patients who had available molecular data of both D+28 and 12 months, fifty nine (62.1%) patients had less than 40% of BCR-ABL1 transcript (VEMR) on Day+28. Among them, 49 (83.1%) patients achieved MMR at 12 months. However, only 27.8% (10 out of 36 patients) of patients without VEMR achieved MMR (p<0.0001). Among 72 patients who had available molecular data of both D+28 and 36 months, forty-six (63.9%) patients achieved VEMR. In 46 VEMR patients, 43 (93.5%) patients achieved MMR at 36 months. However, 80.8% (21 out of 26 patients) of patients without VEMR achieved MMR (p=0.10). Three-year overall survival (OS) & progression-free survival (PFS) rates were 98.0% and 95.1%, respectively. Three-year PFS rates for VEMR and no VEMR group were 98.4% *vs* 88.8% respectively (p=0.04).
Summary/Conclusion: Our study shows that VEMR at 1 month can be a strong predictor for further molecular responses as well as long-term outcome. Therefore, it would be helpful to monitor BCR-ABL1 transcript level at 1 month in patients who treated with more potent TKIs.

PB1915

THE RESTORING OF DEEP MOLECULAR RESPONSE IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND MOLECULAR RELAPSE AFTER TREATMENT DISCONTINUATION

E. Chelysheva[1,*], A. Turkina[1], V. Shuvaev[2], A. Bykova[1], G. Gusarova[1], O. Shukhov[1], A. Petrova[1], M. Vakhrusheva[1], S. Goryacheva[1], L. Kolosova[1], M. Fominykh[2], I. Martynkevich[2], A. Abdullaev[1], A. Sudarikov[1], V. Savchenko[1]

[1]National Research Center for Hematology, Moscow, [2]Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russian Federation

Background: Discontinuation of tyrosine kinase inhibitors (TKI) treatment in patients (pts) with chronic myeloid leukemia (CML) having deep molecular response (DMR) now is moving from clinical trials into routine clinical practice. The loss of major molecular response (MMR) with *BCR-ABL*>0.1% by IS is generally defined as a molecular relapse and a trigger to restart therapy. The *BCR-ABL* level at molecular relapse and the impact of the delay in treatment resuming after MMR loss which may happen in routine clinical setting are rarely evaluated.
Aims: To evaluate the restoring of DMR in CML pts after resuming of TKI therapy in accordance with the time of therapy restart.
Methods: We observed 70 pts with CML (68 in chronic phase, 2 in accelerated phase at diagnosis) who stopped TKIs being in stable DMR>1 year. DMR was considered as at least MR4 (*BCR-ABL*<0.01%). The follow-up was done by quantitative PCR detection of *BCR-ABL* level. The data were collected retrospectively and prospectively in 2 central clinics of Moscow (n=66) and St.Petersburg (n=4) during years 2008-2016 outside of clinical trials. The reasons to stop TKI were toxicity (n=30), pregnancy (n=18) and patients' decision (n=22). Median (Me) time of observation after TKI cessation was 29 months (range 3-120). The low/intermediate/high Sokal risk group was in 45(64%)/ 14(22%)/ 9(14%) of pts respectively. Imatinib/nilotinib/dasatinib/bosutinib were used before treatment cessation in 45 (64%)/ 15(21%)/ 9(13%)/ 1(2%) of pts. Me time of TKI therapy was 6 years (IQR 4-9). Me time of DMR duration was 1.8 years (IQR 2.8-5). TKI were resumed after MMR loss or by physician's decision. The delays in treatment restart were related to drug access, patients' decisions or pregnancy. Event free survival (EFS) was evaluated considering MMR loss, TKI resuming and death as the events. Cumulative incidence (CI) of DMR restoring was evaluated in accordance with the time since MMR loss to TKI restart.

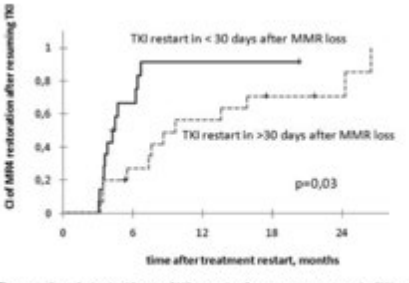

Figure 1. Cumulative incidence of MR4 regain after treatment restart in CML patients

Figure 1.

Results: The EFS after TKI discontinuation was 69%, 50% and 39% at 6,12 and 24 months(mo) accordingly. Two patients with DMR died from cardiovascular disease. TKIs were resumed in 38 (54%) pts, no MMR loss was in 6 pts at treatment restart. The MMR loss occurred in 32 (46%) of pts with the Me of *BCR-ABL* level 0.54% by IS (range 0.11% -13%). Me time from MMR loss detection to TKI resuming was 38 days (range 3-276). Treatment was restarted within<30 days in 14 pts and later than 30 days in 18 pts. MR2 loss (BCR-ABL>1%) without hematologic relapse (HR) was in 16 pts at TKI resuming. No HR occurred in 4 pts with MR2 loss and treatment delay of 111-276 days. A HR was observed in 2 pts who did not restart treatment in 122 and 155 days after MMR loss. The same TKI was reinitiated in 30 pts. TKI change due to previous toxicity or by administrative reasons was in 7 pts and 1 pt accordingly. TKI was also changed in 1 pt without MR2 after 6 mo of treatment restart and a DMR was achieved thereafter. Me time of observation after TKI resuming was 24 mo (range 2-116). CI of DMR regain was 73% and 100% after 12 and 24 months of treatment restart. DMR regain was observed later in pts who resumed TKIs later than 30 days after loss of MMR (figure 1).
Summary/Conclusion: A leukemic clone in CML patients may remain sensitive to TKI during prolonged treatment interruptions. However the delays in treatment restart may lead to a HR and a switch to other TKI may be required. CML patients should have regular molecular monitoring during off-treatment period and after TKI resuming.

PB1916

SURVIVAL AFTER 1, 3 AND 5 YEARS OF TYROSINE KINASE INHIBITOR THERAPY IN SIMPLICITY, AN OBSERVATIONAL STUDY OF CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA (CP-CML) PATIENTS IN ROUTINE CLINICAL PRACTICE

M. Michallet[1,*], J. Cortes[2], C. Gambacorti-Passerini[3], R. Hehlmann[4], L.A. Williams[2], S.L. Goldberg[5], C. Davis[6], F. De Solda[6], G.P. Sen[7], S. Gajavelli[6], M. Mauro[8]

[1]Centre Hospitalier Lyon Sud, Lyon, France, [2]MD Anderson Cancer Center, Houston, United States, [3]San Gerardo Hospital di Monza, Monza, Italy, [4]ELN-Foundation, Weinheim, Germany, [5]John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, [6]Bristol-Myers Squibb, Princeton, [7]ICON Plc, San Francisco, [8]Memorial Sloan-Kettering Cancer Center, New York, United States

Background: Data on survival in CP-CML outside clinical trials are limited. SIMPLICITY (NCT01244750) is an ongoing observational study of CP-CML patients (pts) in routine clinical practice receiving first-line (1L) imatinib (IM), dasatinib (DAS) or nilotinib (NIL) in the US and Europe.
Aims: To describe survival in SIMPLICITY pts with 1, 3 and 5 years of follow-up after start of 1L IM, DAS or NIL.
Methods: Demographics and clinical characteristics are given for pts alive at 5 years and pts who died by 5 years for the overall prospective population and 1L tyrosine kinase inhibitor (TKI) cohorts. Descriptive p-values were generated using Chi-squared tests (categorical variables) and t-tests (continuous variables). Mean survival rate at 1, 3 and 5 years was calculated using the Kaplan-Meier estimator. Mean survival rates are presented for the overall population, for pts who remained on 1L TKI (by 1L TKI) and for pts who switched to 2L TKI (by most recent TKI at follow-up). P-values comparing mean survival rates were based on log-rank test.
Results: By September 07 2017, 1240 pts were enrolled prospectively in SIMPLICITY. Numbers of pts followed for 1, 3 and 5 years were 1192, 1027, and 526 respectively. By Year 3, 50 pts had died, 142 discontinued and 21 pts not reached 3-year follow-up. By Year 5, 78 pts had died, 240 discontinued and 396 pts had yet to reach 5-year follow-up. Median (interquartile range; min–max) age of pts was 55 (47–65; 19–87) years in pts alive at 5 years and 71 (65–78; 19–90) years in pts who had died by 5 years. Other demographics were comparable, but pts alive at 5 years had a mean (±standard deviation) number of comorbidities of 3.2 (±2.6) *vs* 4.6 (±3.3) in pts who had died by 5 years (p<0.001). Patient characteristics were similar across 1L TKI cohorts. Mean survival rate at 1, 3 and 5 years was 99%, 96%, and 93% for the overall population; 98%, 94%, and 91% for 1L IM pts; 99%, 98%, and 96% for 1L DAS pts; and 99%, 95%, and 91% for 1L NIL pts. Mean 5-year survival rates were higher in 1L DAS pts *vs* 1L IM or 1L NIL, pending consideration of confounding variables. The 5-year survival rate was higher for pts remaining on 1L DAS *vs* pts on 2L DAS (97% *vs* 91%; p=0.02); similarly for pts who remained on 1L NIL *vs* pts switched from 1L NIL (95% *vs* 85%; p=0.005). At 5 years 78 pts had died in the overall population over a mean follow-up of 4 years. In the IM, DAS, and NIL cohorts, 36, 13 and 29 pts had died over a mean follow-up of 4–4.25 years. In the overall population, 15 deaths were related to CP-CML, 41 unrelated to CP-CML and 22 had unknown relationship to CP-CML. Of deaths in the IM, DAS, and NIL cohorts, 8, 4 and 3 were related to CP-CML, and 16, 5 and 20 were unrelated to CP-CML.

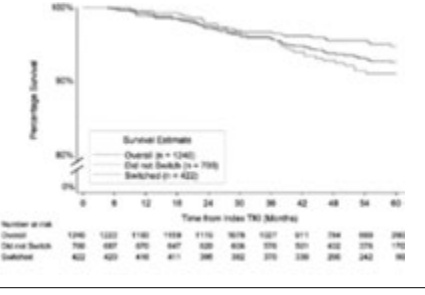

Figure 1.

Summary/Conclusion: Survival rates in the overall SIMPLICITY population, and in pts receiving IM, DAS, and NIL, are high. Survival rates were higher in pts who remained on 1L DAS and 1L NIL than pts who switched.

Survival rates and the proportions of pts who died by 5 years differed between TKI cohorts. Due to the descriptive nature of the statistics, comparisons should be made cautiously. Advanced survival modeling will consider other confounders such as age, gender, etc. These preliminary findings suggest use of TKIs is associated with long-term survival benefit in routine clinical practice. In future analyses with longer median follow-up differences may be discernible between different TKI cohorts and analysis groups.

Background: Two randomized phase 3 trials compared first-line bosutinib *vs* imatinib in patients (pts) with chronic phase chronic myeloid leukemia (CP CML). In BELA (NCT00574873; 2008–2015), Philadelphia chromosome–positive (Ph+) pts received bosutinib 500 mg once daily (QD) or imatinib 400 mg QD; the primary endpoint was complete cytogenetic response (CCyR) rate at 12 mo. In BFORE (NCT02130557; 2014–ongoing), Ph+ or Ph–/*BCR-ABL*+ pts received a lower bosutinib starting dose (400 mg QD); the primary endpoint was major molecular response (MMR) rate at 12 mo in the modified intent-to-treat (ITT) population (Ph+ pts with e13a2/e14a2 transcripts).
Aims: Efficacy of bosutinib (400 and 500 mg QD) and imatinib (400 mg QD in both trials) was assessed after ≥12 mo of follow-up from BFORE and BELA, respectively; the safety profile of bosutinib 400 and 500 mg QD was also evaluated.
Methods: Efficacy outcomes were reported for the ITT population, except where noted for the BFORE study. Treatment-emergent adverse events (TEAEs) were assessed in all pts who received ≥1 bosutinib dose, regardless of Ph+ or transcript status.

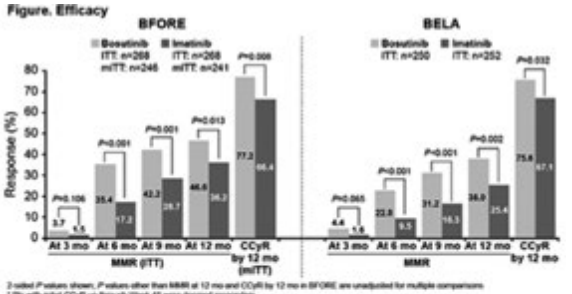

Table. Safety

n (%)*	BFORE Bosutinib 400 mg QD n=268		BELA Bosutinib 500 mg QD n=248	
	Any grade	Grade 3/4	Any grade	Grade 3/4
Any TEAE	263 (98)	151 (56)	238 (96)	162 (65)
Diarrhea	188 (70)	21 (8)	172 (69)	27 (11)
Thrombocytopenia	94 (35)	37 (14)	78 (31)	34 (14)
Alanine aminotransferase increased	82 (31)	51 (19)	78 (31)	44 (18)
Aspartate aminotransferase increased	61 (23)	26 (10)	65 (26)	20 (8)
Anemia	50 (19)	9 (3)	58 (23)	19 (8)
Vomiting	48 (18)	3 (1)	79 (32)	8 (3)

* Select TEAEs in ≥20% of pts in either study

Figure 1.

Results: Clinically meaningful and consistent improvements in MMR rates at 6, 9, and 12 mo with bosutinib *vs* imatinib, as well as in CCyR rate by 12 mo, were seen in BFORE and BELA (**Figure**). Consistent with the ITT population in BFORE, the MMR rate at the 12-mo visit was higher with bosutinib than imatinib (47.2% *vs* 36.9%; *P*=0.02) in the modified ITT population. Despite improved CCyR rate by 12 mo, BELA did not meet the primary endpoint of CCyR rate at 12 mo (bosutinib 70% *vs* imatinib 68%; *P*=0.601); in BFORE, CCyR rate at 12 mo was not assessed, as pts with a CCyR but no MMR prior to the 12-mo visit may not have had a cytogenetic assessment at this time point per protocol. Transformation to accelerated/blast phase was similar with bosutinib *vs* imatinib in BFORE (1.5% *vs* 2.2%) but less frequent in the bosutinib arm in BELA (1.6% *vs* 4.8%). Median bosutinib dose intensity (relative dose intensity) was 392 mg/day (98%) in BFORE and 482 mg/day (96%) in BELA; corresponding values for imatinib were 400 mg/day (100%) in both studies. The safety profile of bosutinib was generally similar in BFORE and BELA, except for a lower rate of vomiting (18% and 32%, respectively; **Table**). No new safety signals were identified for bosutinib in BFORE. Lower percentages of bosutinib-treated pts in BFORE *vs* BELA had grade 3/4 TEAEs (56% *vs* 65%; study drug–related 49% *vs* 57%), serious TEAEs (20% *vs* 25%), dose delays due to TEAEs (57% *vs* 63%), and dose reductions due to TEAEs (34% *vs* 37%). A higher percentage of bosutinib-treated pts remained on study drug after ≥12 mo of follow-up of BFORE *vs* BELA (78% *vs* 71%) with lower discontinuation rates due to TEAEs (14% *vs* 21%).
Summary/Conclusion: Increased physician experience in TEAE management with the lower bosutinib starting dose in BFORE *vs* BELA (400 *vs* 500 mg QD) likely contributed to the success of BFORE. Despite differences in study endpoints, bosutinib dose, and era of tyrosine kinase inhibitor therapy, the improved efficacy profile with bosutinib *vs* imatinib in newly diagnosed pts with CP CML was consistent between BFORE and BELA.

MYELOID-DERIVED SUPPRESSOR CELLS IN CHRONIC MYELOID LEUKEMIA

A. Ahn[1,*], C.-J. Park[1], Y.-U. Cho[1], S. Jang[1], E.-J. Seo[1], M.-H. Bae[2], D.-H. Lee[3], J.-H. Lee[4], J.-H. Lee[4], K.-N. Koh[5], H.-J. Im[5], J.-J. Seo[5]

[1]Department of Laboratory Medicine, University of Ulsan College of Medicine and Asan Medical Center, [2]Department of Laboratory Medicine, Hanyang University College of Medicine, Guri Hospital, Seoul, [3]Department of Laboratory Medicine, Gyeongsang National University Hospital, Jinju, [4]Department of Internal Medicine, [5]Department of Pediatrics, University of Ulsan College of Medicine and Asan Medical Center, Seoul, Korea, Republic Of

Background: Myeloid-derived suppressor cells (MDSC) represent phenotypically heterogeneous populations of myeloid cells at different stages of maturation, which are able to suppress tumor-specific T cell response. MDSC are produced from normal granulocytic precursors in emergent states such as carcinoma and inflammation. Increases in MDSC have been reported in several hematologic malignancies including plasma cell myeloma, chronic lymphocytic leukemia, and acute myeloid leukemia.
Aims: This is a prospective study that measured frequencies of MDSC and we evaluated the significance and disease correlation of MDSC in patients with chronic myeloid leukemia (CML).
Methods: Peripheral blood (PB) (n=77) and bone marrow (BM) (n=76) aspirates were obtained from 6 pediatric and 60 adult patients diagnosed with CML. The status of CML included chronic (n=30), accelerated (n=3), blastic phases (n=4), and complete hematologic response (CHR) after treatment (n=40). A total of 40 PB samples were collected from age and sex-matched healthy controls (HC). Thirty eight patients who underwent staging work-up of lymphoma, but without BM involvement, were recruited for BM negative controls (NC). We measured the number of MDSC by flow cytometry using the FACSCanto II flow cytometer and FacsDIVA software (Becton-Dickinson Inc, CA, USA). We acquired 50,000 cells and quantified the frequencies of 2 subsets of MDSC, granulocytic MDSC (gMDSC, HLA-DRlowCD11b+CD14–CD33+CD15+) and monocytic MDSC (mMDSC, HLA-DRlowCD11b+CD14+) in PB and BM.
Results: The correlation between BM-gMDSC% and PB-gMDSC% was good (r=0.712, *P*<0.001) and BM-gMDSC% was linear to PB-gMDSC% (y=0.960x+4.101, r^2=0.507). BM-gMDSC% and PB-gMDSC% showed negative correlation with *BCR-ABL1* quantitation (r=–0.478 and r=–0.547, *P*<0.001, respectively). BM-gMDSC% at diagnosis (mean±SD; 5.8±13.8%) were significantly lower than that of the CHR (40.6±16.4%) and BM NC group (37.8±11.3%) (*P*<0.001, respectively) (Fig.1). BM-gMDSC% was lower in the *BCR-ABL1* positive CHR group (23.4±18.3%) as compared to the *BCR-ABL1* negative CHR group (31.4±14.1%), but not statistically significant (*P*=0.123). PB-gMDSC% at diagnosis (8.7±14.4%) was also significantly lower than that of the CHR (22.8±11.2%) and HC groups (27.7±10.9%) (*P*<0.001, respectively). However, there was no statistical difference in the mMDSC% in both BM and PB. The overall survival rate of

the high BM-gMDSC% group (≥20%) was higher than that of the low BM-gMDSC% group (<20%) in both diagnosis and CHR groups (*P*=0.430 and *P*=0.011, respectively). However, both BM-mMDSC% and PB-mMDSC% did not show significant differences between each group.

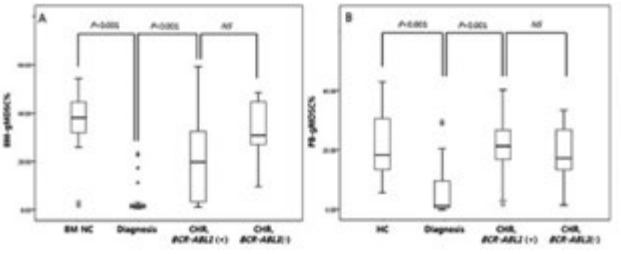

Figure 1.

Summary/Conclusion: BM-gMDSC% and PB-gMDSC% at diagnosis were significantly lower than those of BM NC and HC, respectively. Higher gMDSC% at CHR might be related to good prognosis in CML patients. These findings are contrary to the known MDSC findings in other malignancies. Granulocytes in CML are differentiated from leukemic stem cells, and probably the emergent myelopoietic condition does not affect the granulopoiesis of CML. The increased MDSC in CHR might reflect the regeneration of normal granulopoietic precursors.

PB1919

INTOLERANCES AND HOSPITALIZATIONS AFTER 1, 3 AND 5 YEARS OF TKI THERAPY IN SIMPLICITY, A STUDY OF CHRONIC-PHASE CHRONIC MYELOID LEUKEMIA PATIENTS IN ROUTINE CLINICAL PRACTICE

M. Mauro[1,*], S.L. Goldberg[2], C. Gambacorti-Passerini[3], B. Simonsson[4], C. Davis[5], F. De Solda[5], G.P. Sen[6], S. Gajavelli[5], J. Cortes[7]

[1]Memorial Sloan-Kettering Cancer Center, New York, [2]Hackensack Meridian Health, New Jersey, United States, [3]University of Milano Bicocca, San Gerardo Hospital di Monza, Monza, Italy, [4]Uppsala Universitet, Uppsala, Sweden, [5]Bristol-Myers Squibb, Princeton, [6]ICON Plc, San Diego, [7]MD Anderson Cancer Center, Houston, United States

Background: Deeper insight is needed into the safety of tyrosine kinase inhibitors (TKIs) in chronic-phase chronic myeloid leukemia (CP-CML) outside clinical trials. SIMPLICITY (NCT01244750) is an ongoing observational study of CP-CML patients (pts) in routine clinical practice receiving first-line (1L) imatinib (IM), dasatinib (DAS) or nilotinib (NIL) in the US and Europe.
Aims: This analysis describes intolerances and reasons for hospitalizations (collectively defined as 'events') in the retrospective/prospective SIMPLICITY cohorts, in pts with 1, 3 and 5 years (yrs) of follow-up (FU) after start of 1L TKI.
Methods: Events collected consisted of intolerances on TKI change (dose change, discontinuation, or switching) and reported hospitalizations and associated reason. Demographics are given for pts with ≥1 event, and those with no events, by 5 yrs. Mean (±SD) number (no.) of events during 1, 3 and 5 yrs of FU are presented for the overall population, by 1L TKI, and in pts remaining on 1L TKI *vs* those switching in the FU period. Pts discontinuing 1L TKI without switching to 2L TKI were excluded from the analysis. Common adverse events (AEs; all grades) are given by system organ class (SOC) for the overall population and will be given for the specified sub-cohorts.
Results: By September 07 2017, 1492 pts were enrolled in SIMPLICITY, of which 454, 666 and 720 pts had ≥1 events by 1, 3 and 5 yrs (of which 446, 586 and 357 pts had ≥1, 3 and 5 yrs of FU), and 990, 736 and 637 pts had no events (of which 961, 627 and 293 pts had ≥1, 3 and 5 yrs of FU). The median (interquartile range [IQR]; min–max) age of pts was 61 (50–71; 19–95) yrs in pts with ≥1 event and 52 (43–64; 18–91) yrs in pts with no events by 5 yrs. Pts with ≥1 event by 5 yrs had a higher mean (±SD) no. of comorbidities (3.8 [±2.9] *vs* 2.5 [±2.4]) than pts with no events (p<0.001). There was a mean (±SD) of 2.6 (±2.2) events in 454 pts with ≥1 event by 1 yr: 3.4 (±2.6) events for pts who switched *vs* 2.1 (±1.7) events in pts remaining on 1L TKI. There were 3.3 (±3.2) events in 666 pts with ≥1 event by 3 yrs: 4.2 (±3.6) events for pts who switched *vs* 2.3 (±2.4) events in pts remaining on 1L TKI. There were 3.7 (±3.8) events in 720 pts with ≥1 event by 5 yrs: 4.7 (±4.3) events for pts switching *vs* 2.6 (±2.6) in pts remaining on 1L TKI. There were differences between cohorts, with pts receiving 1L NIL having the highest no. of events at 1, 3 and 5 yrs (3.0, 3.9 and 4.1 *vs* 2.3, 3.0 and 3.4 for DAS [p=0.02, p=0.009, p=0.08], 2.5, 3.2 and 3.7 [p=0.06 p=0.04, p=0.29] for prospective IM, and 2.8, 3.2 and 3.7 [ns] for retrospective IM). Across TKIs, common AEs by SOC were gastrointestinal disorders (27.8%, 29.4% and 31.5% by 1, 3 and 5 yrs), blood/lymphatic disorders (24.0%, 19.8%, and 19.4% by 1, 3 and 5 yrs), respiratory disorders (15.9%, 20.7% and 24.2% by 1, 3 and 5 yrs), and skin/subcutaneous disorders (14.5% and 14.1% by 1 and 3 yrs). No. and reasons for death will be presented.
Summary/Conclusion: Events were more frequent in pts switching *vs* those remaining on 1L TKI, and inter-cohort comparisons showed the no. of events to be highest in 1L NIL pts at all time points. The no. of pts with events increased with longer FU. Common AEs are similar to those reported for TKIs in pivotal trials. SIMPLICITY is not designed to comprehensively capture these events, and thus presented data may offer a snapshot of TKI profiles. Our findings suggest, in routine clinical practice, events accrue with time, are associated with TKI switch, and vary by TKI; further analysis is ongoing.

PB1920

TARGET: A SURVEY OF REAL-WORLD MANAGEMENT OF CHRONIC MYELOID LEUKEMIA ACROSS 33 COUNTRIES

A. Turkina[1,*], J. Wang[2], V. Mathews[3], G. Saydam[4], C.W. Jung[5], H. Al Hashmi[6], M. Yassin[7], T. Hughes[8]

[1]Scientific and advisory department of hemotherapy of myeloproliferative disorders, National Research Center for Hematology, Moscow, Russian Federation, [2]Chinese Academy of Medical Sciences and Peking Union Medical College, Institute of Hematology and Blood Disease Hospital, Tianjin, China, [3]Department of Haematology, Christian Medical College, Vellore, India, [4]Department of Hematology, Ege University Hospital, Izmir, Turkey, [5]Samsung Medical Center, Seoul, Korea, Republic Of, [6]Adult Hematology and Hematopoietic Stem Cell Transplant Department, Oncology Center King Fahad Specialist Hospital, Dammam, Saudi Arabia, [7]National Center for Cancer Care and Research, Doha, Qatar, [8]South Australian Health and Medical Research Institute, Adelaide, Australia

Background: Despite the availability of multiple guidelines for the management of chronic myeloid leukemia (CML), technical, financial and educational challenges, among others, may prevent some physicians from implementing these recommendations. In this context, the TARGET survey was developed by a Steering Committee consisting of 8 international hematologists (from Australia, China, India, Qatar, Russia, Saudi Arabia, South Korea, and Turkey).
Aims: The aims of the TARGET survey were to: I. Assess the current care of patients with CML in the participating countries compared with international guideline recommendations; II. Identify the challenges faced by physicians in implementing these recommendations; III. Develop practical solutions to support physicians in optimizing the management of CML patients.
Methods: Data were collected via a self-administered questionnaire, completed online, from 1-Apr-17 to 31-Aug-17. It included 23 questions divided into 7 sections (physician's profile, CML diagnosis, molecular monitoring and mutation analysis, treatment objectives, treatment efficacy, treatment toxicities, treatment discontinuation) and 7 clinical cases. The survey covered multiple regions worldwide (Africa, Asia, Australia, Middle East, Russia & Turkey) with 33 participating countries and was available in English, Russian, Turkish and Chinese. The analysis was performed using MODALISA software. Results are reported descriptively.
Results: Of the 1008 physicians contacted, 614 completed the questionnaire. The majority (59%) were male and practiced in Russia (19%), China (13%), India (12%), Turkey (8%) & S.Korea (7%). Most respondents (67%) had been treating CML for >10 years; 30% had personally seen 20-50 CML patients in the previous year. Molecular monitoring: 26% did not have access to a standardised PCR test and a further 52% were unaware of when the last standardization had occurred. Despite 89% of respondents knowing that BCR-ABL levels should be assessed every 3 mths in the first 12 mths of treatment, this was only achieved in clinical practice for 51% of respondents with cost being the main barrier (48%). Treatment toxicities: 4% respondents would change treatment for persistent Grade 1 adverse events (AEs). In contrast, 81% & 90% would do so for Grade 3/4 hematological & nonhematological AEs. Opinions were divided in the case of persistent Grade 2 AEs (59% would switch for nonhematological AEs). Treatment Free Remission (TFR) was considered by few (6%) as their primary treatment goal. Achieving deep molecular response was recognized by 47% as a prerequisite for TFR. The major hurdles for attempting TFR in current practice were lack of guidelines (30%), and insufficient molecular monitoring capability (21%-frequency and/or sensitivity). Management of

patients with a "warning" response also yielded mixed responses based on the clinical cases: 53% followed the ELN guideline recommendation of 'watch & wait' whilst 47% adjusted the hypothetical patient's treatment. Similarly, in the clinical case study of a patient receiving imatinib 400mg/day with an optimal response (MMR at 12 mths) but not in deep molecular response at 24 mths, 41% would change the patient's treatment.
Summary/Conclusion: The TARGET survey identified several gaps in current CML management when compared with international guidelines. Practical solutions to address these gaps are currently being developed.

Background: Several tyrosine kinase inhibitors (TKIs) are available for treatment of patients with chronic myeloid leukaemia in chronic phase (CML-CP).
Aims: We analysed different TKI modalities used as therapy for CML-CP in a long-term analysis.
Methods: In a retrospective cohort analysis, we included data from patients with CML-CP treated in clinical practice with TKI modalities at Spanish Registry of CML (RELMC) (17 hospitals around all the country) between 2000 to 2014. The main aim of the study was to describe the sequence of TKI treatment, in real life practice and the rate of last deep molecular response (DMR) (MR^4, $MR^{4.5}$ or undetectable transcript) in each scheme.

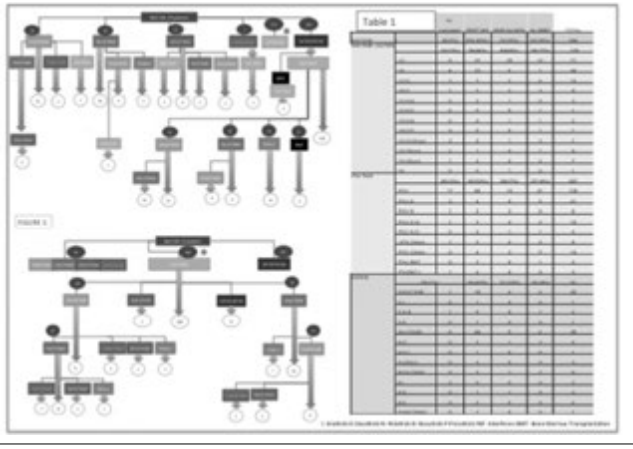

Figure 1.

Results: Our analysis included 862 patients with CML in first chronic phase treated with TKIs in first line or after Interferon alpha. **Demographics** 517 M, 345 F, median age: 52 y (14-94). Sokal Index distribution (low 49% Inter 38% High 13%), EURO Index distribution (low 50% Inter 45% High 5%), EUTOS Index distribution (low 93% High 7%), LT-EUTOS Index distribution (low 68% Inter 25% High 7%). **Schemes of treatment:** Table 1 summarizes all the schemes used and the last molecular response. Patients were divided in 4 groups depending of TKIs treatment. Group 1: Only treated wit Imatinib 394(45,7%) Group 2: Imatinib and then 2ºGTKIs due to intolerance or failure 170 p (19,7%) (12 schemes of sequential TKIs treatment) Group 3 2ºGTKs in first line 91 p (13 sequential schemes) (10,5%) Group 4 Interferon alpha and then ITKs: 207 (24%)(9 sequential schemes). Figure 1 summarizes evolution of different treatments around 14 years. **Last deep molecular response:** With a median of follow up of 82 months (1-351 months) from diagnosis, 77 months (1-311 months) from first treatment and 70 months (1-191 months) from first TKI treatment. The rates of deep molecular response for each group were (G1: DMR 65% MMR 13% No MMR 15%, G2: DMR 46% MMR 24% No MMR 17% G3: DMR 62% MMR 13% No MMR 12% G4: DMR 53% MMR 17% No MMR 18%). **Long-term survival (PFS or OS):** We did not find statistical differences between groups of treatment, either from diagnosis, first treatment or first TKI. Reaching a deep response guarantees better outcomes. **Predicting variables:** SOKAL, EUTOS, EURO and LT-EUTOs indexes continue to be useful in predicting long-term outcome.
Summary/Conclusion: In the setting of a multicentric, hospital-based CML registry, treatment with TKIs is very variable, resulting in a great number of sequential combinations of TKI. The rate of deep molecular response is roughly 60% in patients treated with imatinib and not needing change of TKI, and in those treated upfront with 2ºGTKI, but appears lower in patients treated with imatinib upfront, but who need to switch to 2ºGTKIs. Survival outcomes were not different, although it is worth to point out the shorter follow-up of patients treated upfront with 2ºGTKIs.

IMPACT OF BCR-ABL TYROSINE KINASE INHIBITORS ON THE SURVIVAL AND FUNCTIONS OF ENDOTHELIAL CELLS

H. Haguet[1,2,*], J. Douxfils[1], C. Chatelain[1], C. Graux[3], A. Wannez[1], F. Mullier[2], J.-M. Dogné[1]

[1]Pharmacy department, University of Namur, Namur, [2]Hematology Laboratory, [3]Hematology department, CHU UCL Namur, Yvoir, Belgium

Background: BCR-ABL tyrosine kinase inhibitors (TKIs) are the mainstay of the treatment from chronic myeloid leukemia (CML). However, new generation TKIs (dasatinib, nilotinib, bosutinib and ponatinib) increase the risk of arterial occlusive events compared with the first generation (imatinib). To date, the mechanism(s) of these side effects is poorly understood but clinical data suggest that new generation TKIs might accelerate atherogenesis, in which endothelial cells play major function (e.g. lipid deposition, leukocyte recruitment).
Aims: This research aims to determine the effect of BCR-ABL TKIs on endothelial cell survival and major functions (endothelial cell migration and expression of adhesion molecules) using an *in vitro* model.
Methods: All experiments were performed on endothelial cells derived from human umbilical vein (HUVEC). Viability after 24h of TKI treatment was assessed using MTS and LDH assays following standard protocols. Reactive oxygen species (ROS) generation was quantified using a ROS detection reagent (CM-H2DCFDA) following the manufacturer instructions. The cell-surface expression of 3 adhesion molecules (ICAM-1, VCAM-1 and E-selectin) after 4-hour TNF-α activation (10ng/mL) was measured by on-cell ELISA and flow cytometry. Migration of endothelial cells was evaluated by a scratch assay (*i.e.* scratch of a confluent monolayer with a pipette tip and monitoring of the wound closure by inverted microscopy).
Results: Dasatinib, nilotinib and ponatinib at high concentration reduce cell metabolism indicating an inhibition of proliferation or induction of apoptosis by these 3 TKIs. Additionally, high-dose ponatinib (0.5µM) induces necrosis as demonstrated by increased LDH release. The analysis of ROS generation demonstrates that the 5 TKIs do not induce oxidative stress and do not alter cell viability by this way. Leukocyte recruitment is also an important process in atherogenesis and requires the expression of adhesion molecules by activated endothelial cells. The expression of ICAM-1, VCAM-1 and E-selectin was quantified by on-cell ELISA in HUVEC which demonstrated a decreased of ICAM-1, VCAM-1 and E-selectin expression with dasatinib, nilotinib and ponatinib at high concentration (0.5µM, 2µM and 0.5µM respectively) and no or little impact of imatinib and bosutinib. This reduction correlates with the decreased viability of endothelial cells with these 3 treatments, an hypothesis that has been confirmed by flow cytometry. Finally, we evaluate the migration ability of endothelial cell after treatment by scratch assay. High dose dasatinib inhibits endothelial cell migration whereas other TKIs do not have any impact. Therefore, dasatinib might induce arterial occlusive events through impaired vascular wound healing.
Summary/Conclusion: Over the 5 commercialized BCR-ABL TKIs, dasatinib, nilotinib and ponatinib possess the most impact on endothelial cells. They reduce viability by inducing apoptosis, necrosis or inhibiting cell proliferation, which possibly help to the development of atherosclerosis through impaired endothelium permeability, enabling migration and trapping of lipoprotein into the intima. Additionally, dasatinib reduces endothelial cell migration, which might contribute to formation of arterial thrombosis. Determination of mechanism(s) by which TKIs promote cardiovascular events is required to implement appropriate risk minimization measures and select patients to whom the prescription of these drugs should be avoided.

PB1923

COMPARISON OF MOLECULAR RESPONSES AND OUTCOMES IN CHRONIC MYELOID LEUKEMIA-CHRONIC PHASE PATIENTS TREATED WITH NILOTINIB INITIALLY FOLLOWED BY IMATINIB, COMPARED TO TREATMENT WITH IMATINIB UPFRONT

A. Jain*, A. Irom, M. Mahapatra, T. Seth, R. Saxena, S. Sazawal

Clinical Hematology, AIIMS, New Delhi, Delhi, India

Background: In CML-CP, Imatinib remains the drug of choice for frontline therapy in resource constrained countries, despite newer Tyrosine Kinase Inhibitors. However, Nilotinib/Dasatinib although costlier, have the advantage of earlier and deeper molecular responses. Giving Nilotinib for the first 3 months and then switching to Imatinib to capitalise on the quicker and deeper responses without adding substantially to the cost of treatment has never been studied before.
Aims: To compare the molecular responses and long term outcomes in treatment naïve CML-CP patients treated with Nilotinib for the initial 3 months followed by Imatinib compared to treatment with Imatinib upfront.
Methods: Newly diagnosed treatment naïve CML –CP patients affording therapy, who gave consent were included in the study. Accelerated phase/blast crisis patients were excluded. Patients were divided into 2 groups. Group 1 received Imatinib 400 OD upfront. Group 2 received Nilotinib 300BD for 1st 3 months and then were switched over to Imatinib 400 OD after 3 months. Clinical and lab follow up with complte blood counts and quantitative RT-PCR for Bcr-abl was done at 3, 6 and 12 months.
Results: 21 patients in group 1 and 18 patients in Group 2 were enrolled and followed up. Mean age was 37.4 and 38.16 yrs respectively. Group 2 had more males than group 1 (77.77% *vs* 33.33%, p value 0.006). Sokal score profile was not statistically different in both the groups (low risk: 33.33%vs 22.22%, intermediate risk: 28% *vs* 44.44%, high risk: 38% *vs* 33.33%). The mean RQPCR for bcr-abl was significantly higher at 3 months in patients in Group 1 compared to Group 2 (Table 1). A warning response was also more common in Group 1. The 6 and 12 month responses were however not significantly different in both the groups. In Group 2, there were 5 patients (1 Sokal low, 3 intermediate and 1 high risk) who achieved optimal response at 3 months, however had loss of response at 6 months (3) and 12 months (2). Only 1 patient on Imatinib had loss of respose at 6 months.

Table 1. RQPCR for bcr abl at various time points in both groups.

	3 months			6 months			12 months		
	Group 1	Group 2	P	Group 1	Group 2	P	Group 1	Group 2	P
N (data available for)	18	17		16	16		9	13	
Mean	21.67	2.424	0.018	2.182	3.703	0.47	1.333	3.05	0.5745
>10%	6	0	0.01	2	3	0.63	0	1	0.48
>1 to 9.99 %	9	9	0.86	3	4	0.67	2	2	0.49
>0.1 to 0.99%	3	5	0.37	4	4	0	0	3	0.20
<0.1%	0	3	0.06	7	5	0.47	7	7	0.07
AP/BC	1 (AP)	1 (BC)		0	0		0	0	

Summary/Conclusion: Nilotinib shows significantly better responses than Imatinib at 3 months. This early advantage with Nilotinib is not sustained over time with both groups having similar responses at 6 and 12 months. Furthermore, patients may lose the initial reposnse on Nilotinib and progress when switched to Imatinib. However achieving early molecular responses almost always results in good long term outcomes. Thus the duration of Nilotinib may have to be increased to benefit the majority of the patients before switching over to Imatinib.

PB1924

IS THE TIME TO CYTOGENETIC RESPONSE PREDICTIVE FOR SURVIVAL IN CHRONIC MYELOID LEUKEMIA? POPULATION DATA FROM RUSSIAN CML REGISTRY AND SIMULATION MODEL

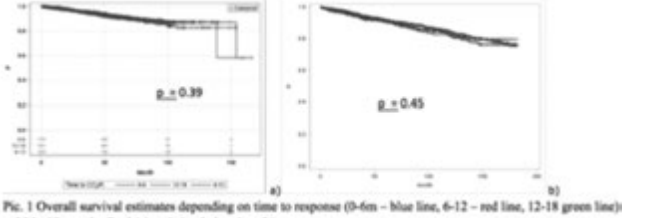
S. Kulikov[1,*], A. Kulikovsky[1], O. Lazareva[2], A. Turkina[2], A. Golenkov[3], T. Pospelova[4], S. Kutsev[5], J. Shatokhin[6], T. Konstantinova[7], A. Zaritzkey[8], E. Parovichnikova[9], V. Savchenko[9]

[1]Laboratory of Biostatistics and Information Systems, [2]Department for chemotherapy of myeloproliferative disorders, National Research Center for Hematology, [3]Regional Scientific Research Clinical Institute named after M.F. Vladimirsky, Moscow, [4]Hematology Center of Novosibirsk, Novosibirsk, [5]Research Centre for Medical Genetics, Moscow, [6]State Medical University, Rostov, [7]Sverdlovsk Regional Clinical Hospital No. [1], Ekaterinburg, [8]Almazov National Medical Research Center, St.-Petersburg, [9]National Research Center for Hematology, Moscow, Russian Federation

Background: The belief that "not only the response, but also the early response to therapy" predicts the best long term clinical outcome is common in chronic myeloid leukemia (CML). The latest data do not confirm that time to response is relevant for overall survival.
Aims: The aim of this study was to check it on the data of the Russian CML Registy and on simulation model.
Methods: Russian CML Registry include more than 10 thousand patients (pts) data. In the analysis 8326 CML pts in chronic phase(CP) with first line TKI therapy were included: 91% of pts were treated by Imatinib and 9% by other TKIs. Mean age was 47.3 years, 4607 f / 3705 m. Date of Complete Cytogenetic Response (CCyR) was assessed as the date of first test with 0% of Ph'+ cells or date of molecular test with BCR/ABL ≤0.1% IS. Overall survival (OS) was estimated starting land-mark (LM) time point, event was death from any reason, date of last contact was censored for alive pts. Survival analysis and simulation was performed by SAS statistics. Distribution of time to response and to death was modeled as mixture of exponents with parameters fitted to real data.
Results: Firstly we followed traditional way and compared overall survival estimates (OS) depending upon the response status (yes/no) at several LM time points (table 1,a).There are significant differences in OS at all LMs as expected. Then in the analysis we included only responded pts at a LM time =18 months and compared OS in 3 groups with different times to response: 0-6 months, 6-12 months, 12-18 months (pic.1,a). There are no significant differences in OS. The COX regression analysis also does not find significant influence of time to response on the OS. The distribution of time to response was fitted by the mixture of 3 exponents related 3 groups of responders: fast-runners, moderate-runners and resistant pts. The parameters was following: 1 group: 6.5m, 60%, 2 group: 35 m, 32%, 3 group: 220 m, 8%, where fist value is mean time to respond, second-portion in cohort. Then we suppose that mean life duration in 1 and 2 groups equal to 50years, and for 3 group-9 years. The simulation results for n=5000 pts is displayed in table 1, b and picture 1, b.*:* The deal is that in LM analysis you compare the group of fast-runner with mixture of slow runners and "never" responders. The result depends upon the proportion of compounds in the second group. So, our analysis does not confirm significant correlation of the survival and speed of respond.

Table 1. LM OS estimates of responder *vs* non-responders, all p<0.001. Real (a) and simulation (b) data.

LM	a) Real registery data	b) Simulation data
	10years OS, CCyR vs nonCCyR	10years OS, CCyR vs nonCCyR
6m	82% vs 73%	84% vs 74%
12m	85% vs 67%	84% vs 69%
18m	86% vs 63%	83% vs 67%



Pic. 1 Overall survival estimates depending on time to response (0-6m – blue line, 6-12 – red line, 12-18 green line) at LM =18 month. Real (a) and simulation data (b).

Figure 1.

Summary/Conclusion: The population of CML pts is a mixture of "any time" responders and "never"-responders. Tradition LM analysis output is wrong treated as evidence that survival depends of the time to respond. More specific analysis does not confirm that. This was demonstrated on big population data and explained by simulation model.

PB1925

GASTRIC CONDITIONS AS PROXY FOR HELICOBACTER PYLORI INFECTION AND RISK OF CHRONIC MYELOID LEUKEMIA

G. Larfors[1,*], J. Richter[2], A. Själander[3], L. Stenke[4], M. Höglund[1]

[1]Department of Medical Sciences, Uppsala university, Uppsala, [2]Dep of Hematology, Oncology and Radiation Physics, Skåne university hospital, Lund, [3]Department of Public Health and Clinical Medicine, Umeå university, Umeå, [4]Department of Medicine, Karolinska institutet, Stockholm, Sweden

Background: Although the pathophysiological mechanisms in chronic myeloid leukemia (CML) have been elucidated to a large degree, no etio-

logical risk factors have been clearly established. Slightly simplified, we know a lot about what happens, but we know little of why. Peptic ulcers in CML patients have been reported for long, but it was only recently that a study found an increased incidence of ulcers before onset of CML, indicating a common etiological mechanism, rather than ulcers being a consequence of the malignancy. As Helicobacter pylori is both a known risk factor for ulcers, and a known carcinogen, it could serve as a candidate for such a common risk factor.
Aims: To evaluate a possible relationship between chronic Helicobacter infection and risk of CML by using previous gastric conditions or medication as proxy variables for Helicobacter infection.
Methods: In a matched case-control design, 980 patients registered in the Swedish CML Register and diagnosed between 2002 and 2012 were compared to 4960 control subjects, randomly selected from the Swedish population and matched on age, sex, and region of residence. Records of previous medical conditions and prescribed medications were retrieved from the National Patient Register and the Swedish Prescribed Drug Register, respectively. From these and other registers, data were further collected on potential confounders such as co-morbidities and socio-economic status.
Results: Compared to controls, CML cases significantly more often had a previous diagnosis of dyspepsia, gastritis, or peptic ulcer, with odds ratios between 1.8–2.0. Adjustments for socio-economic factors and co-morbidity did not substantially change these estimates. Furthermore, previous prescription of proton pump inhibitors was more frequent among CML cases than controls (OR 1.5, p=0.0005). Meanwhile, neither inflammatory bowel disease nor the intake of non-steroid anti-inflammatory drugs were associated with CML, indicating that it is not gastrointestinal ulcer or inflammation per se which influences risk.
Summary/Conclusion: The present study provides epidemiological evidence consistently linking certain previous gastric conditions or medications to CML risk. All of these conditions have known correlations to Helicobacter pylori infection. Although far from decisive, the data indicate that H pylori could be involved in CML carcinogenesis. H pylori is a known carcinogen, but has previously not been implicated in myeloid malignancies. The findings call for further studies with biological material from CML patients, to validate the possible relationship.

PB1926

EVOLUTION OF PLASMA LEVELS, RESPONSE AND TOLERANCE TO IMATINIB AFTER SWITCHING FROM GLIVEC® TO GENERIC IMATINIB IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE (CML-CP)

A. Wojnicz[1], J. Cornago[2], V. Vaitekovich[3], C. Mba[3], E. Sola[2], C. Martínez[4], J.L. Steegmann[2,3,*]

[1]Clinical Pharmacology Dpt and IIS-IP, [2]Hematology Dpt. Hospital de la Princesa, [3]IIS-IP. Hospital de la Princesa, [4]Pharmacy Dpt. Hospital de la Princesa, University Hospital La Princesa, Madrid, Spain

Background: Although switching to generic imatinib is increasingly used across the world, mainly because of economic reasons, there is a paucity of information regarding the effects of this switch on plasma levels, response and treatment tolerance.
Aims: Primary: Determine and compare plasma levels of imatinib after switching from Glivec to generic imatinib. Secondary: To assess if response or tolerance are changed after switching.
Methods: Imatinib plasma levels, BCR-ABL (IS) values and tolerance were measured before switching (while the patient was taken Glivec), and after 1 month and 3 months of treatment with generic imatinib (all patients took the same brand of generic imatinib). The study was approved by the Ethics committee, and all patients gave their informed consent. Plasma levels were measured using liquid chromatography tandem mass spectrometry method as previously published by our group. BCR-ABL values are expressed in IS. Cmin, Cmax, BCR-ABL values and standard hematologic and biochemistry values (including PTH and CK values) were entered in the statistic model. Descriptive statistics, means comparison and correlations were done using SPSS package.
Results: All patients treated in our institution with Glivec were included. As most of our patients with CML are treated upfront with 2G TKI, only 15 patients have been included. The median duration of Glivec treatment before switching was 109 months (11-191). All patients but one (ID:1961) were at MR4 or better at baseline. At baseline, all the patients had adequate Cmin values(≥1µg/mL), except one (ID:1181), who has indetectable transcript at that time. After change to generic Imatinib, all samples showed adequate Cmin values, except two (ID:752, +1m and ID 1961, +3m). When comparing baseline with 1 month and 3 month values, there were no significant differences between the mean values of Cmin, BCR-ABL values and standard hematologic values. The only significant difference was between phosphate baseline and 1-month values (3±0.43 *vs* 2.77±0.27 mg/dl; p=0.039). As regard to response, all patients with MR4 or better maintained this kind of response, and the same occured with the patient with MMR. Concerning tolerance, there was no change in adverse events (AE) in any patient. In patient 1252, as plasma levels at baseline, 1m and 3m were higher than 1.8µg/mL, and considering that he had multiple low-grade toxicity, dose was reduced at 3m, with amelioration of AE.

Table 1.

ID PAC	Dose Glivec	BCR-ABL Baseline	Glivec Cmin*	BCR-ABL 1m	Ima. Cmin. 1m	BCR-ABL 3m	Ima. Cmin. 3m

* Cmin values are expressed as µg/mL. #Dose of Pt 1252 was diminished to 300 mgld at 3m. Table 1.

Summary/Conclusion: Taking into account the limitation of our study (small sample size), it seems that changing from Glivec to generic Imatinib is not associated with significant changes in Cmin Imatinib values, BCR-ABL values or adverse events. The prompt and simultaneous measurement of plasma levels and molecular response has allowed us to reassure patients about the change, and to adjust the dose in one patient, diminishing the toxicity. Based on these results, we conclude that this approach is useful in patients whose treatment is switched from Glivec to generic imatinib.

REAL-WORLD EVIDENCE OF MOLECULAR RESPONSE TO TYROSINE KINASE INHIBITORS FROM CHINA SUPPORTS EUROPEAN LEUKEMIANET 2013 RECOMMENDATIONS FOR THE MANAGEMENT OF CHRONIC MYELOID LEUKAEMIA

H. Yin[1,*], Y. Chen[1], L. Chen[1], Y. You[1], P. Zou[1], L. Meng[2], W. Li[1]

[1]Hematology, Union Hospital, Tongji Medical College of Huazhong University of Science and Technology, [2]Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science And Technology, Wuhan, China

Background: Currently, there lacks available real-world clinical efficacy data on different strategies, such as comparing the efficacy of frontline nilotinib with imatinib and the efficacy of second-line nilotinib in Pts resistant or intolerant to imatinib. Meanwhile, when to apply the second generation of TKIs instead of the first generation of TKIs as well as their clinical efficacy hasn't been defined.
Aims: The present study was aimed to explore these issues and optimize clinical therapy through evaluating molecular response at specific milestones according to ELN guidelines.
Methods: We have enrolled 319 Pts from our hospital from January 2000 to December 2017 who were newly diagnosed with CML. 29 Pts received frontline nilotinib and the other 290 received imatinib .The study was descriptively analyzed and evaluated the efficacy of imatinib and nilotinib.
Results: At data collection, CML-CP was confirmed in 309 of 319 Pts who were newly diagnosed, and CML-AP was confirmed in 10 of 319 the Pts. 210 (65.8%) Pts were male. Median follow-up was 45 (range 3 to 199) months and median age was 39 (range 2 to 76) years. The molecular responses of frontline therapy at ELN2013 milestones during the observation period are shown in Table 1. During the observation period, 84/290(29%) Pts with frontline imatinib switched to nilotinib; 32/84 switched early (within 12 months) and 52/84 switched later.Rates of CCyR at any time for Pts who switched early and later were 90.6%(29/32) and 88.5%(46/22) (*P*=0.756).Rates of MMR at any time for Pts who switched early and later were 84.4%(27/32) and 76.9%(40/52) (*P*=0.409). The documented main reason for first switch was treatment failure[(50/84(59.5%) Pts, medium time was 19.5 months] while 12/84 Pts (median time was 11 months) were switched for "warning", 15 (17.9%) Pts were switch for intolerance(median time was 21 months), 6/84 (7.1%) Pts were switched for

willing to withdrawal (medium time was 25.5 months) and one for unexplained eosinophilia(time was 35 months). Rates of CCyR and MMR at any time for Pts who switched TKI following a prior "warning " response were 83.3%(10/12) and 75%(9/12). Rates of CCyR and MMR at any time for Pts who switched TKI following a prior "failure " response were 86%(43/50) and 72%(36/50). 206/290 Pts remained on frontline imatinib with no observed switch. In the 54/206 Pts following "warning" response, 22/54 had a "failure" response at one or more ELN2013 milestones. In the 133/206 Pts following "optimal" response, 4/133 had a "failure" response and 1/133 had a "warning" response. Rates of CCyR and MMR at any time for Pts who remained on frontline imatinib following a prior "warning" response were 87.0%(47/54) and 66.7%(36/54). Rates of CCyR and MMR at any time for Pts who remained on frontline imatinib following a prior "failure" response were 78.9%(15/19) and 63.2%(12/19). Rates of CCyR and MMR at any time in Pts were 93.1%(270/290) and 82.8%(240/290) separately, significantly higher than that in the frontline imatinib group and similar to the rate of CCyR and MMR(100% and 86.2%) in the frontline nilotinib group.

Table 1.

Table 1. Comparison of frontline therapy outcomes

Response	first-line TKI (n = 319)		p value
	Nilotinib (n=29)	Imatinib(n=290)	
EMR or PCyR by 3 months	96.6% (28/29)	51.3% (138/269)	0.00C
BCR-ABL1IS≤10% or CCyR by 6 months	92.9% (26/28)	58.2% (164/282)	0.00C
MMR rate by 12 months	85.2% (23/27)	68.0% (176/259)	0.064
MMR rate by 18 months	95.2% (20/21)	77.3% (184/238)	0.054
CCyR rate overall	100% (29/29)	84.1% (244/290)	0.02C
MMR rate overall	93.1% (27/29)	77.9% (226/290)	0.054
CCyR rate at any time	100%(29/29)	83.8%(243/290)	0.025
MMR rate at any time	86.2%(25/29)	65.9%(191/290)	0.025
PFS rate	96.6% (28/29)	97.2% (282/290)	0.831
EFS rate	82.8% (24/29)	40.7% (118/290)	0.00C

Abbreviations:CCyR,Complete Cytogenetic Response;PCyR,Partial Cytogenetic Response; EMR,Early molecular response;MMR,Major molecular response;EFS,event-free survival; PFS,survival free from progression to AP or BP.

Summary/Conclusion: As the first-line drug for newly diagnosed CML Pts, Nilotinib can achieve a deeper molecular response in a shorter time than imatinib. According to ELN's suggestion, the clinical efficacy of Pts who switch early to nilotinib for resistant or intolerant to imatinib can reach similar efficacy as the first-line nilotinib. Overall, the results support the use of ELN2013 recommendations to guide TKI management.

Background: The results of long-term follow-up of patients with chronic myelogenous leukemia (CML) do not lose their importance. The use of TKI (imatinib, IM) resulted to dramatic improvement in survival, so probability of CML-related death for patients (pts) could be significantly lower than chance of dying due to common mortality causes besides than CML.
Aims: To analyze overall survival (OS) and causes of mortality in CML pts treated in routine clinical practice in Russian Federation for a long period (>12 years) of time.
Methods: The analyzed cohort consisted of 607 Ph/*BCR-ABL*-positive CML pts from 29 regions of Russia (ELN OSP EUTOS) diagnosed in 2002- 2006 with IM therapy initiation ≤6 months (mo) after diagnosis established. Median (Me) of age was 48(18-82) years (y), 47% males. Pretreatment regimens were as follows: hydroxyurea 454(76%) pts; chemotherapy 25(4%) pts, IFN-α 37(6%) pts. Chronic phase (CP) of CML was diagnosed in 557 (93%) pts, accelerated phase (AP)-38(6%) and blast crisis (BC)-in 6(1%) pts. The number of patients with CML according to years of diagnosis were: 2002-15pts, 2003-38pts, 2004-46pts, 2005-206pts, 2006-302pts. Last database update had been made on Nov. 2017 for 473 pts; in addition, 134 pts from 2 regions were updated in 2015.
Results: The median follow-up was 92,4 (1- 170,3) mo. At 12 years, OS was 50%(figure 1); OS by age groups were: 20-40yy- 68%, 40-60yy- 69%, 60-80yy- 40%. Mortality in the whole cohort of 607 pts was 27% (168 pts). Of these 168 pts, 91(54,2%)pts deaths were as results of CML progression to AP or BP including non-complaent cases; 3pts (1,7%) were reported as died in CP CML, 3pts (1,7%)-after allogeneic stem cell transplantation (2 due to infection complications), in 19 (11,4%) cause of death was unknown. Deaths caused by concomitant diseases were in 52 cases (31%): coronary artery disease/myocardial infarction/heart failure in 18 cases, acute ischemic stroke in 8 cases, second malignancies (Cr) in 8 cases (lung tumor, metastatic esophageal Cr, stomach Cr, brain tumor, Cr of the sigmoid colon, Cr of rectal and colon, melanoma, renal Cr), accidents-2 cases, liver cirrhosis in 2 pts, in 2 cases-respiratory virus infections complicated with pneumonia and others.

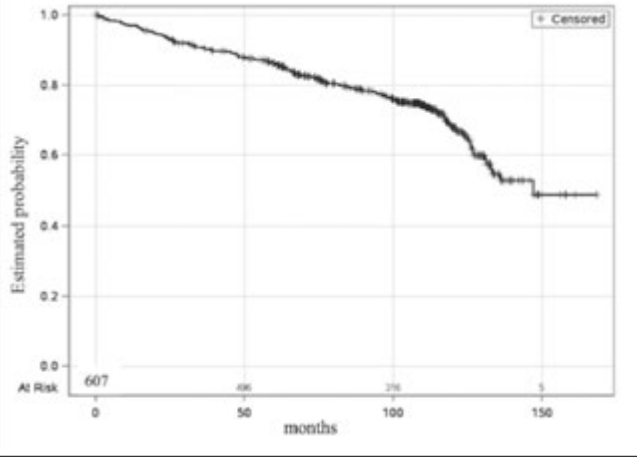

Figure 1.

Summary/Conclusion: Long-term follow-up of patients participated in the tracked cohort of 607 patients in the OSP EUTOS study allowed to characterize the results of OS and the cause of death according to age and comorbidity. The cause of death in our study in 34% of cases was unrelated to CML, which corresponds to the reference data (Castagnetti 2013, Hehlmann 2014, Pfirrmann 2015). Mortalities related to cardiovascular causes and second malignancies in pts with CML have significant proportion (50% and 15% from the whole mortality, respectively). A substantial reduction of OS from 78 to 50% is observed after 8 to 12 years of TKI therapy due to cohort aging and dying out for ordinary reasons.

PB1929

IMATINIB TREATMENT IN ELDERLY PATIENTS WITH CHRONIC MYELOID LEUKEMIA (CML) IN THE REAL-LIFE SETTING: UPDATED DATA OF THE CERRAHPASA CML COHORT

D. Ozmen[1,*], M. Oztas[2], F. Bektas[2], A.E. Eskazan[1], M. Pehlivan[1],

S. Sadri[1], D. Keskin[1], N. Ozgur Yurttas[1], T. Elverdi[1], A. Salihoglu[1], M.C. Ar[1], S. Ongoren[1], Z. Baslar[1], Y. Aydin[1], T. Soysal[1]

[1]Department of Internal Medicine Division of Hematology, [2]Department of Internal Medicine, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Tyrosine kinase inhibitors (TKIs) are the mainstay of chronic myeloid leukemia (CML) treatment. Median age of CML at diagnosis is 50 years, but a significant proportion of the patients (pts) are diagnosed after age 60. Pts with CML in chronic phase (CML-CP) nowadays live near-normal lifespans, thus, the number of elderly CML pts with comorbidities started to increase.This brings out the issues regarding TKI toxicities, medication adherence and responses to TKI therapy, and we have previously presented the real-life data regarding toxicity and efficacy of imatinib (IM) in our elderly CML cohort [Blood. 2016;128:1905].
Aims: The aim of this study is to update the previously presented data showing the efficacy and safety of IM in the elderly population (pts≥60 years; Group A) with CML and to compare these data with younger patients (pts<60 years; Group B).

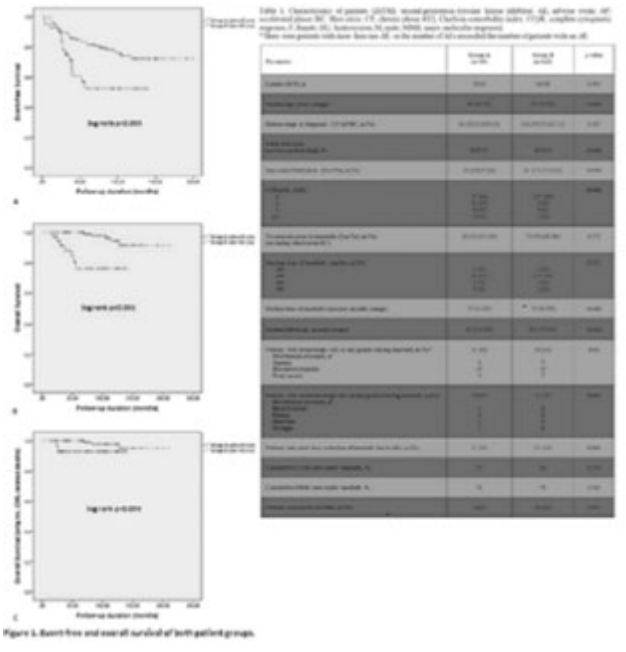

Figure 1.

Methods: Patient demographics, dose and duration of IM therapy, disease risk scores, cytogenetic and molecular responses, comorbidities, adverse events (AEs), follow-up durations and outcomes were evaluated from pts' files, retrospectively. The Charlson Comorbidity Index (CCI) of each patient was calculated as stated before [Haematologica. 2011;96(10):1457-61].
Results: Our cohort consisted of 181 pts with a median age of 46 years (range, 18-83 years). Group A consisted of 39 pts, and there were 142 pts in Group B (Table 1). The two groups were balanced regarding gender, disease stage, therapies prior to TKI, and the starting dose of IM. There were more pts with intermediate and high Sokal risk scores in Group A (p<0.001), and pts in Group A had significantly more comorbidities (p<0.001) with higher CCI scores (p<0.001). Median time of IM exposure (p<0.001) and follow-up durations (p<0.001) were significantly longer in Group B than those of Group A. There were significantly more hematologic AEs among pts in Group A than those of Group B (26% *vs* 10%, p=0.01). Nonhematologic AEs were significantly more common in Group A (20% *vs* 7%, p=0.022), and the rates of pts with IM dose reduction due to AEs were significantly higher in Group A than that of Group B (28% *vs* 11%, p=0.006). Cumulative complete cytogenetic and major molecular response rates and the percentage of patients who switched to second-generation TKIs were similar in both groups (Table 1). Event-free (Fig.1A) and overall (OS) (Fig.1B) survival rates were significantly higher in Group B than those of Group A (p=0.005 and p<0.001, significantly). There were 7 and five pts who died during the follow-up in Groups A and B, respectively. Among these deaths, 5 pts in Group A and two pts in Group B died due to non-CML related causes, and the OS rates were comparable when non-CML related deaths were excluded (Fig.1C) (p=0.096).
Summary/Conclusion: Although TKI therapy is relatively safe and effective in elderly pts with CML-CP, TKI-related AEs are more common in this population and comorbidities may play a role in the generation of TKI toxicities and outcomes. Prompt and timely management of these AEs and TKI dose modifications may lead to better outcomes. In our patient cohort, inferior OS rates were observed among elderly pts, but OS rates were similar in both groups when non-CML related deaths were excluded.

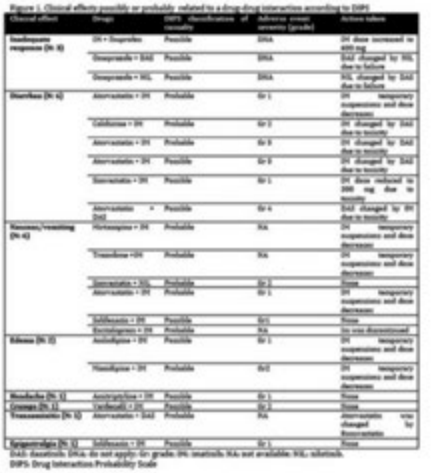
Background: Imatinib and the newer BCR-ABL tyrosine kinase inhibitors (TKIs) are the standard therapy for chronic myeloid leukemia (CML). With these drugs, CML patients are achieving similar survivals than the general population, thus classical aspects of chronic diseases, such as treatment adherence and drug-to-drug interactions (DDI) are becoming more important in patients management. DDIs between TKIs and some concurrent medications could lead to toxicity or inadequate response. Although this is a well known effect, and different guidelines include DDIs as a potencial cause of toxicity or resistance, the information about its frequency and its clinical impact is limited.
Aims: To determine the potential DDIs in CML patients treated with TKIs and its clinical impact.
Methods: This was a retrospective, collaborative study performed in 15 centers within the framework of the Spanish CML Group (GELMC). Each participating center included data from all new CML patients that were diagnosed between 1st January 2014 and 31st December 2015, treated with TKI as first-line therapy for CML in chronic or accelerated phase. Concurrent medications, adverse events (AEs), potential DDI and its potencial effects were analyzed.

Table 1.



Results: A total of 134 TKI treatments, in 105 patients were included. The mean number of concomitant medications was 4,8 (0-19). The mean number of AEs during the first year of treatment was 2 (SD: 1.9, range 0-11). The

AEs severity, according to common terminology criteria for adverse events (CTCAE) 4.03 version, was: grade 1, 40,7%; grade 2, 35,2%; grade 3, 16,1%; and grade 4, 4,8%. Sixtythree patients (60%) had at least one DDI. The mean number of DDIs by TKI treatment was 1,2 (0-8). It was significantly associated with the number of concomitant medications and age. A total of 159 DDIs were detected, involving 55 different drugs, being the most common types, proton pump inhibitors, statins and antidepressants. Clinical or analitical effects of DDIs were suspected by the investigators in only five patients (4,7%). This number increased to 20% in a central review. When such an association was suspected, we applied the DIPS scale (Drug Interaction Probability Scale) to try to estimate causality. We detected 21 clinical effects in 21 patients (20%), that according to the DIPS scale were possibly or probably related to a DDI: 18 (86%) of these effects were related to toxicity, and 3 (14%) to inadequate response (Figure 1). Most of these AEs attributed to DDIs were mild. The most common were diarrhea, vomiting, edema, cramps and transaminitis, and 78,5% were grade 1-2. We did not find significant differences in the frequency of AEs, or in the molecular response, in patients with or without DDIs.

Summary/Conclusion: Potential DDIs are present in most of patients treated with TKIs. A clinical effect was suspected by the treating phisycians in only 4.7% of the patients, but increased to 20% in the central review. Nevertheless most of this possible or probable clinical effects were mild, and could possibly had appeared with the individual drugs, thus it is difficult to be sure to what extent the DDIs have caused or worsened the AEs. We did not see a clear effect of DDI in response as a group, although 3 patients with inadequate response were taking drugs that could decrease TKI effectivity. Thus, due to DDIs high frequency, and the possibility of clinical relevant effects, we consider that physicians treating CML patients should consider this aspect in their patients management.

Abstract withdrawn.

PB1932

ANALYSIS OF SERUM LIPIDS, CARDIOVASCULAR RISK AND INDICATION FOR STATIN THERAPY AT THE START AND DURING IMATINIB AND NILOTINIB THERAPY IN *DE NOVO* CML PATIENTS RESULTS FROM REAL-LIFE PROSPECTIVE STUDY

T. Horňák*, L. Semerád, D. Žáčková, B. Weinbergerová, Z. Šustková, J. Procházková, J. Mayer, Z. Ráčil

Department of Internal Medicine, Hematology and Oncology, Masaryk University and University Hospital Brno, Brno, Czech Republic

Background: Nilotinib (NILO) administration in CML patients (pts) is known to be associated with impairment of lipid metabolism, which is one of the possible risk factors leading to cardiovascular (CV) adverse events (AE) of NILO. On the contrary, these abnormalities were not observed during imatinib (IMA) treatment. A routine protocol for lipid and CV risk assessment at the start and during both TKIs administration is still not established.

Aims: 1) To analyse the serum lipids levels and CV risk in *de novo* CML pts treated with NILO and IMA at baseline and during the therapy. 2) To identify CML pts who meet the criteria for a hypolipidemic treatment according ESC/EAS guidelines at diagnosis and during the TKI therapy.

Methods: Consecutive pts diagnosed with CML between 6/2014-7/2017 treated with NILO or IMA in the 1st line were included in this prospective study. The selection of TKI was based on treating physician's decision. Patients received clinical and laboratory diagnostic workup and CV risk assessment according to ESC/EAS at the start of TKI therapy and then every 3 months for two years. Changes in serum lipids levels were analysed only in pts without hypolipidemic therapy at the study visit.

Results: Thirty- four pts treated with IMA and 23 with NILO were included in this trial (median follow-up: IMA=12m, NILO=9m). Pts in NILO group were significantly younger compared to IMA (median age-45 *vs* 67 yrs; p=0.0006) and had significantly less comorbidities (diabetes mellitus 0% *vs* 32%, p=0.0018; ischemic heart disease-0% *vs* 24%; p=0.0163). The baseline CV risk SCORE value of NILO pts was also significantly lower (SCORE-median-6% *vs* 1%; p=0.009). Moreover, there were significantly more pts already or newly indicated for statins at the start of IMA [IMA 68% (7/34 pts on statin, 16/34 pts newly indicated) *vs* NILO 30% (3/23 pts on statin, 4/23 newly indicated); p=0.0076]. These differences between groups reflect common selection of TKIs by treating physicians based on their known AEs. Baseline levels of total- and LDL- cholesterol (CHOL) between groups were not different, but this could be affected by different percentage of patients already on statins in both groups. During the first 6 months of treatment the level of total- and LDL- CHOL in NILO pts significantly increased. Total- and LDL- CHOL did not change in IMA pts. HDL cholesterol significantly increased in both groups (Table). During the first 6 months 2/34 (6%) IMA pts and 3/23 (13%) NILO pts previously classified at low CV risk moved to high or very high CV risk category (p=ns). No new CV event occurred in both groups. The number of pts additionally indicated for statin therapy during the first 6 months of TKI treatment was similar in both groups [IMA *vs* NILO-2/34 (5,9%) *vs* 2/23 (8,7%); p=ns].

Triacylglycerols M6 median (mmol/l)	1.28		1.32	

* only data of pts without hypolipidemic therapy at the time of study visit were analysed

Summary/Conclusion: Our prospective real-life study clearly showed the routine selection of TKI by treating physician in *de novo* CML based on comorbidities and age. Importantly, there is high percentage of patients with *de novo* CML in central European population who fulfil criteria for statins already at the start of TKI therapy (53% in our study). Even though NILO increases the total/LDL- CHOL, the increase of CV risk and number of pts newly indicated for statin therapy does not differ from the IMA group, at least not during the first 6 months of therapy. However, this may be influenced by mentioned routine selection of TKI in CML patients and also longer follow-up is needed.

PB1933

IMPACT OF KINASE DOMAIN MUTATIONS ON SECOND LINE NILOTINIB THERAPY IN CHRONIC MYELOID LEUKEMIA CHRONIC PHASE-REAL WORLD DATA FROM A DEVELOPING COUNTRY PERSPECTIVE

S. Francis Thekkudan*, A. Sharma, A. Gupta, S. Nityanand

Hematology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

Background: Nilotinib is a second generation tyrosine kinase inhibitor (TKI) approved for adults with newly diagnosed chronic myeloid leukemia (CML) in chronic phase (CP) and those with Imatinib-resistant or intolerant CML-CP and CML in accelerated phase (AP). The occurrence and impact of baseline as well as evolving kinase domain (KD) mutations on Nilotinib therapy were assessed in this study. Also, no Indian data is available till date on the efficacy of second line nilotinib and this study reflects a real world data from a developing country with resource-constrained setting.

Aims: Primary objectives were to assess the molecular response as well as the prevalence, pattern and evolution of KD mutations before and during second line Nilotinib therapy in CML- CP patients.

Methods: Patients of CML-CP aged ≥18 years, who developed Imatinib-resistance or Imatinib-intolerance and thus switched to second line Nilotinib therapy, were included. KD mutation analysis was done retrospectively in the stored cDNA of samples extracted for BCR ABL analysis, by Sanger's direct sequencing. Mutation analysis was repeated when there was a sub-optimal response/loss of response at 6 months and 12-month time points.

Results: Of the total 674 newly diagnosed CML patients presented from January 2013-June 2016, 85 (12.6%) patients were started on Nilotinib, of which 11 patients were non compliant/irregular in follow up and thus excluded from further analysis. 18 patients (24.3%) had BCR-ABL KD mutations at the time of switch over to Nilotinib. Median duration of Nilotinib therapy was 32.4 months, with a minimum follow up of at least 12 months. Optimal response was achieved in 70.27% patients at 6 months of Nilotinib therapy, of which major molecular response (MMR) rate was

24.3%. All 18 patients who achieved MMR at 6 months continued to maintain MMR till last follow up (median duration-28.6 months). Of the suboptimal responders, 54.5% patients had evolution of new mutations at 6 months. At 1-year end point, 45.9% patients achieved MMR and 42.8% of the suboptimal responders had evolution of new mutations, especially in P-loop and A-loop domains. Number of mutations per patient increased with time, with more of double and triple mutants evolving at 6 month and 1-year time points. When stratified according to presence or absence of any mutations at switch over, significantly better MMR rates at 1 year were seen in mutation negative group (20% *vs* 55.5%, p= 0.014). Estimated 4-year overall survival and EFS of the cohort was 93.3% and 38.6%. Only 4 (5.4%) patients developed Grade III-IV hematologic toxicity. 2 patients who developed blast crisis died.

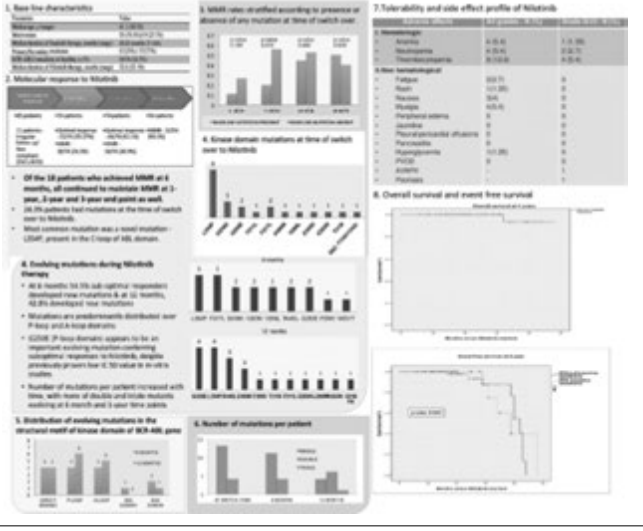

Figure 1.

Summary/Conclusion: Nilotinib is an effective second line TKI with 24.3%, 45.9% and 59.2% MMR rates at 6 months, 1 year and 2 year, respectively. Achievement of MMR at 6 months predicts long-term stable molecular remissions.So, earlier and deeper molecular kinetics can be used as a prognostic marker to identify low-risk patient subsets. Evolving new unfavourable mutations are major causes of treatment failure. In contrary to ELN guidelines, all new mutations need not necessarily imply to label a TKI failure and does not warrant a change in therapy, especially in a developing country like India. Side effects are usually well tolerated, most common being cytopenias. Large-scale studies with long-term follow up are required for assessing the durability of sustained MMR with Nilotinib and to broaden the spectrum of clinically significant mutations influencing the TKI therapy.

IMATINIB RESPONSE AND MICRORNAS PROFILE IN CML-A BIOMARKER FOR DRUG RESPONSE

R.S. Alves[1,2], A.C. Gonçalves[1,2], J. Jorge[1,2], D. Luís[3], A. Ribeiro[3], G. Marques[4], L. Jorge[4], P. Rodrigues-Santos[5,6], P. Freitas-Tavares[3], A. Almeida[7,8], A.B. Sarmento-Ribeiro[1,2,3,9,*]

[1]Coimbra Institute for Clinical and Biomedical Research (iCBR)-Group of Environment Genetics and Oncobiology (CIMAGO), [2]Laboratory of Oncobiology and Hematology, Faculty of Medicine University of Coimbra (FMUC), [3]Clinical Hematology Department, [4]Clinical Pathology Department, Centro Hospitalar e Universitário de Coimbra (CHUC), [5]Immunology Institute, Faculty of Medicine University of Coimbra (FMUC), [6]Immunology and Oncology Laboratory, Center for Neurosciences and Cell Biology (CNC.IBILI), Coimbra, [7]Hospital da Luz, [8]CEDOC-Chronic Diseases Research Center, Lisboa, [9]Center for Neurosciences and Cell Biology (CNC.IBILI), University of Coimbra, Coimbra, Portugal

Background: The introduction of Imatinib and other Tyrosine Kinase inhibitors (TKIs) in the treatment of Chronic Myeloid Leukemia (CML) changed the course of this disease dramatically. Despite the higher therapeutic efficacy of different TKIs, CML cells develop mechanisms that overcome the therapeutic effect becoming resistant. The actual challenge is to predict which patients will develop resistance to TKIs, in order to improve therapeutic selection. Several mechanisms are described as necessary for resistant phenotypes, like BCR-ABL point mutation or overexpression, influx/efflux drug transporters expression (such as P-gP and OCT1), and alternative signaling pathways activation (like PI3K/Akt/mTOR). All these mechanisms are extremely controlled in cells, and microRNAs (miRs) are essential regulators of gene expression. In this context, the miRs profile could play a critical role in Imatinib response/resistance.
Aims: The aim of this work was investigated the role of miR-21, miR-519c, miR-451 and miR-26 expression levels in CML patients at diagnosis and correlated the expression levels of this miRs with Imatinib response.
Methods: For that, we assessed the expression levels of miR-203, miR-21, miR-519c, miR-451, miR-26 and miR-16 (endogenous control) by TaqMan MicroRNA Assays, in 29 CML patient samples at diagnosis. The study population presented a median of 53 years old, with 52% of males, and 86% of the patients were diagnosed at chronic phase. The proper statistical analysis was performed and was considered a significance levels of 95% ($p<0.05$).
Results: : The miR-451 was the miR with higher expression levels (median: 7.3), the miR-26 show a median of expression of 0.086, and the miR-21 presented the lowest levels (median: 0.0003). The expression of miR-519c was not detected in any sample. The expression levels of the evaluated miRs was independent of the phase of disease at diagnosis. Moreover, we evaluated the potential use of miRs expression as a biomarker of response to Imatinib at 6 and 12 months of treatment follow-up. The ROC analysis show that patients with miR-451 expression levels higher than 5.69 and lower expression levels of miR-21 than $1.16x10^{-4}$ have an optimal response to Imatinib at 12 months [AUC 0.77 (CI95% 0.58-0.95); Sensibility=92%; Specificity=64%; p=0,017; AUC 0.77 (CI95% 0.57-0.97); Sensibility=55%; Specificity=100%; p=0,021, respectively]. The patients with this profile combining miR-451 and miR-21 according to the cut-off levels have 44.8x higher probability of achieving an optimal response at 12 months. In opposition, patients with miR-451 expression levels lower than 5.69 and higher expression levels of miR-21 than $1.16x10^{-4}$ present 21.6 times lower probability to achieve an optimal response at the same time point.
Summary/Conclusion: Our preliminary results suggest that miRs profile in CML patients at diagnosis could constitute a new biomarker of Imatinib response, particularly the levels of miR-451/miR-21. However, more studies are necessary with a higher number of patients. The work was supported by FMUC and Banco Santander Totta (FMUC-BST-2016-214), CIMAGO (Project 10/14) and FCT (SFRH/BD/51994/2012).

IMPACT OF AGE ON THE CLINICAL RESPONSE, TOXICITY AND SURVIVAL IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH IMATINIB IN THE FIRST-LINE: AN ANALYSIS OF CAMELIA REGISTRY

P. Belohlavkova[1], K. Steinerova[2], M. Karas[2], I. Skoumalova[3], P. Rohon[3], K. Indrak[3], J. Voglova[1], E. Cmunt[4], T. Necasova[5], Z. Kristkova[5], M. Trneny[4], P. Zak[1], T. Papajik[3], E. Faber[3,*]

[1]4th Department of Internal Medicine-Hematology, University Hospital and Charles University, Hradec Kralove, [2]Department of Hematology and Oncology, University Hospital and Charles University, Pilsen, [3]Department of Hemato-Oncology, University Hospital and Faculty of Medicine, Olomouc, [4]1st Department of Internal Medicine, Faculty Hospital and Charles University, Prague, [5]Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic

Background: Treatment of chronic myeloid leukemia (CML) patients with imatinib (IMA) significantly prolongs survival. Age is still considered as an important prognostic factor, as it is included in Sokal and ELTS risk scores too. However, several previous studies have demonstrated that the treatment with IMA eliminated the negative effect of the age on the response and survival in CML patients.
Aims: The aim of the analysis was to evaluate optimal response, toxicity, overall survival (OS), progression free survival (PFS), event free survival (EFS) and failure free survival (FFS) according to the age of patients at the time of diagnosis (<65 years *vs* ≥65 years).
Methods: A total of 372 patients (170 women, 202 men) treated with IMA 400 mg/day in the first line were retrospectively evaluated from CAMELIA registry. The median age of diagnosis was 54 (range: 18-88) years. The median follow up was 82.3 (18-177.3) months (M). The patients were divided into two groups: age<65 years (292 patients) and age ≥65 years (80 patients). ELN definitions for treatment response were used. For statistical analysis were used Mann-Whitney and Fisher tests, Kaplan-Meier method with the log-rank test was used for survival analysis.
Results: Elderly patients at the time of diagnosis CML had a statistically higher ECOG score (p=0.001), however leukocyte count and spleen size were statistically lower compared to the younger patients (p=0.028; p=0.034). There were no statistically significant differences in achievement of complete hematologic (CHR), complete cytogenetic (CCyR) and major

molecular responses (MMR) at the optimal time-points between the two groups. Median time to CHR, CCyR and MMR was not different in both groups (3; 12; 35M in younger *vs* 3; 10 and 35M in elderly patients). In the elderly group the incidence of adverse events was higher (p<0.001) as well as more frequent dose reduction of IMA was required in elderly patients (26.3% *vs* 10.3%). There were 35 deaths in the younger group and 18 deaths in the elderly group (12% *vs* 22,5%) but the incidence of CML-related death was comparable in both groups (7.5% *vs* 6.2%). 10-year OS was 86% *vs* 68% (p<0.001) but OS with CML-related death was 96% *vs* 89% without the statistically difference (p=0.07). Non-significant trend to inferior PFS 68% *vs* 84% (p=0.07) was observed in elderly patients. FFS and EFS showed no the statistical difference between both groups (50% *vs* 35%; p=0.43 and 40% *vs* 30%; p=0.39). Patients with a sustained dose of IMA 400 mg/die have better survival in both patient groups but without the statistically differences (p=0.06; p=0.20) (Figure A,B). At present, 173 (67.8%) younger patients and 44 (74.6%) older patients are still treated with IMA.

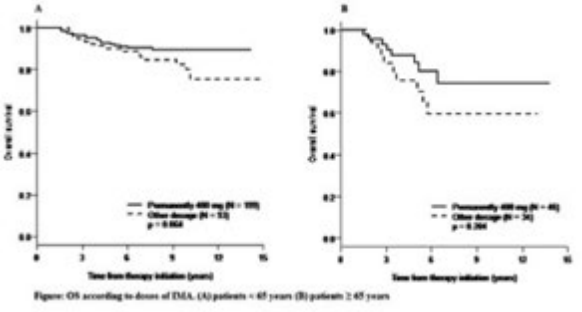

Figure 1.

Summary/Conclusion: Our analysis has shown that the achievement of optimal CHR, CCyR and MMR responses is comparable in both groups. Worse overall survival in the group of patients with age ≥65 is due to the other causes of death than CML. Currently, age at the time of diagnosis CML has lost its negative prognostic significance. The analysis was supported by a research grant from Novartis.

RESULTS OF GENERIC IMATINIB TREATMENT IN SOKAL INTERMEDIATE & HIGH RISK CHRONIC PHASE CHRONIC MYELOID LEUKEMIA PATIENTS IN RESOURCE-CONSTRAINED SETTING: A SINGLE CENTER EXPERIENCE FROM NORTH INDIA

U. Nath[1,*], N. Nagar[2], R. Chetia[2], A. Baveja[2], J. Nanda[2]

[1]Medical Oncology Haematology, [2]Department of Medical Oncology Haematology, All India Institute of Medical Sciences (AIIMS), Rishikesh, Rishikesh, India

Background: The advent of the tyrosine kinase inhibitor (TKI) Imatinib has drastically improved survival in Chronic myeloid leukemia (CML). Recent evidence suggests that patients with Sokal intermediate or high risk CML-CP may preferentially benefit from upfront 2nd generation TKI therapy.[1]
Aims: Our study reports the complete hematological response (CHR) & early molecular response rates at 3 months of treatment with generic Imatinib in newly diagnosed Sokal intermediate & high-risk CML-CP patients in the severely resource-constrained setting of a tertiary care institution in north India.
Methods: The study included 40 newly diagnosed CML-CP patients with either Sokal intermediate or high risk disease, who were diagnosed between March 2016 & October 2017. All the patients in the study hailed from very poor socio-economic background with severe financial constraint, and none of them had any medical insurance. All the patients were treated with generic Imatinib mesylate 400 mg/day which was available free of cost at the hospital. None of the patients could afford one of the two 2nd generation TKI drugs (Nilotinib & Dasatinib) which are available in India, despite adequate counseling & information regarding the efficacy of 2nd generation TKIs. Treatment response was monitored and defined as per European LeukemiaNet recommendations.[2] Hematological response was assessed at 3 months for CHR. Molecular response was assessed at 3 months, 6 months & 12 months of Imatinib treatment if patients could afford BCR-ABL Q-PCR (IS) test.
Results: The median age of patients was 30 years (range 18-75 years). Male:female ratio was 4:3. The median interval from symptom onset to diagnosis was 4 months (range 2-12 months). The median spleen size was 10 cm below costal margin (range 3-28 cm). The median total leukocyte count at diagnosis was 257x10^9/L (range 36-700x10^9/L, and the median platelet count was 338x10^9/L (range 102-1160x10^9/L). At 3 months, CHR was achieved by 90% (36/40) patients; rest had no CHR (Imatinib failure). Molecular response at 3 months could be assessed in 33 out of the 40 patients. Optimal molecular response at 3 months (BCR-ABL ≤10% I.S.) was achieved in 21 out of these 33 patients (63.6%); the rest had BCR-ABL >10%. Imatinib failure was documented at 6 months in 5 patients (BCR-ABL >10% after 6 months). On follow up, major molecular response (BCR-ABL ≤0.1% I.S) at 12 months has been documented in four patients. None of the patients with Imatinib failure could afford BCR-ABL kinase domain mutation analysis. Only one patient switched to Nilotinib therapy after Imatinib failure at 6 months; Imatinib dose has been increased to 800 mg/day in the rest. Five patients have been lost to follow up.
Summary/Conclusion: The real scenario of CML treatment in developing countries with resource-constrained settings is very much different from that in the developed countries. The response rates to generic Imatinib therapy in Sokal intermediate & high risk CML-CP patients are not impressive. There is scope for improvement in treatment response with upfront 2nd generation TKI therapy, if these drugs can be made available at lower costs which each & every CML patient can afford.

HLA CLASS I AND CLASS II ALLELE FREQUENCIES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA AND THEIR EFFECT ON SURVIVAL

I. Kaygusuz Atagunduz[1,*], T. Toptas[1], F. Gecgel[1], T. Memis[2], F. Ture Ozdemiroglu[3], R. Deniz[2], T. Elibol[1], Y. Ipek[1], C. Adiguzel[4], T. Firatli Tuglular[1]

[1]Hematology, [2]Internal Medicine, [3]Immunology, Marmara University Hospital, [4]Hematology, Bahcesehir University Hospital, Istanbul, Turkey

Background: Human Leukocyte Antigens-HLA molecules present pathogens and tumor-derived peptides to T-cells, which initiates an adaptive immune response. Besides the immune response, many studies have shown a correlation between HLA and different etiologies of many diseases, including autoimmune, infectious, neoplastic, and idiopathic diseases. Chronic Myeloid Leukemia (CML) is a clonal myeloproliferative disorder characterized by t (9; 22) translocation. This translocation results in the formation of the chimeric bcr/abl gene encoding the p210 fusion protein. p210 is thought to be a potential endogenous immunogenic tumor-specific antigen. Because these fusion proteins contain peptide sequences that are foreign to the immune system, they may produce a tumor-specific cytotoxic T cell response when presented by the patient's HLA molecules. Some *in vitro* studies indicate that HLA molecules may play a key role in the immune response to CML cells. Many clinical studies have reported a relationship between CML and specific HLA alleles that differ from race to race. In these studies, some HLA alleles are suggested to decrease the occurrence of CML and some HLA alleles are found to be associated with the onset of the disease. However, despite intensive research and several Meta-analyses, the role of HLA in the pathogenesis of CML is still unclear.
Aims: In this study, we aimed to investigate the frequency of class I and class II HLA alleles and to evaluate their effect on survival in the CML patients.
Methods: One hundred and seventy patients with CML diagnosis were included in our study. The age range of the patient group was 19-79 and the median age was 45 years and 50% of the patients were female. The control group (n=426) consisted of healthy donors and 49.5% were female. A comparison of the class I and class II HLA allele types between the patient and control groups was done. Patients and donors in the control group underwent HLA typing by PCR-SSP before the year 2010 and by PCR-SSO after the year 2010.
Results: HLA- B*52, B*55, DRB1*03, DRB1 16 alleles had higher frequencies in the CML patients when compared with the control group and, HLA-A*68, B 35, C 04, C*16, DRB1*04, DRB1*11 ve DQB1*03 allele frequencies were decreased. After the Bonferroni correction, the decrease in the frequency of DQB1*03 allele was found to be statistically significant. (p<0.008; after Bonferroni correction) Overall survival rates for a median follow-up of ten years in patients with and without HLA-DQB1-03 alleles, were 87.5% and 88.5%, respectively, and there was no statistically significant difference between the two groups in terms of overall survival (P=0.57)

Summary/Conclusion: The decrease in the frequency of DQB1*03 alleles in CML patients evaluated in our study suggests that the expression of this allele may have a protective effect for the development of CML. Possibly, the immune response occurring in the presence of the presentation of bcr/abl-derived peptides via DQB1-03 is protective against the development of CML. However, DQB1-03 expression had no effect on the duration of survival in patients receiving tyrosine kinase inhibitors. In light of these results, larger studies addressing the effects of HLA allele expression on the disease course and response to treatment in CML patients are necessary for our population.

PB1938

THE HIGHER THE DOSE OF DASATINIB, THE LOWER THE MOLECULAR RESPONSES AS WELL AS THE GREATER THE DOSE-LIMITING TOXICITIES IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

J. Lee[1,*], S. Lee[1], S.Y. Jung[1], H. Noh[2], H.-Y. Song[3], S.Y. Choi[3], S.-H. Kim[3], D.Y. Zang[4], D.-W. Kim[5]

[1]Department of Pharmacy, Research Institute of Pharmaceutical Sciences, College of Pharmacy, Seoul National University, Seoul, [2]College of Pharmacy, Yonsei University, Incheon, [3]Leukemia Research Institute, The Catholic University of Korea, [4]Department of Internal Medicine, Hallym University College of Medicine, Hallym University Hospital, [5]Department of Hematology, Seoul St. Mary's Hospital, Leukemia Research Institute, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: A fixed dosing regimen of BCR-ABL1 tyrosine kinase inhibitors (TKIs) can lead to under- and over-exposure to the drug in heavy and light-weight patients, respectively.
Aims: The aim of this analysis is to assess the effects of the body surface area(BSA)-adjusted doses of dasatinib on molecular responses (MRs) and dose-limiting toxicities (DLTs) in patients with chronic myeloid leukemia (CML).
Methods: A clinical study was conducted in newly diagnosed adult patients with CML in chronic phase (CP-CML). After adjusting the dose using each patient's body surface area (Dose/BSA), the effects of Dose/BSA were evaluated on the achievement of MRs and the occurrence of DLTs. The MRs were the MR2 defined as BCR-ABL1 transcript<1% on the international scale (IS) at 6 months, equevalent to the complete cytogenetic response, and the major molecular response (MMR) defined as the transcript<0.1% IS at 12 months of dasatinib treatment. A DLT was defined as an interruption or reduction of dasatinib dose owing to any grade 3+ adverse reaction associated with dasatinib treatment by 12 months. Logistic regression analyses were performed to determine the association between the Dose/BSA and the achievement of MRs or the occurrence of DLTs. Chi-square tests were used to compare the MRs and DLTs between the patients divided into quartile groups of Dose/BSA.
Results: The clinical data were collected from all 101 patients enrolled in the study between the year of 2013 and 2017. They were receiving a fixed initial dose of dasatinib 100 mg once daily. The higher the Dose/BSA of dasatinib, the lower the degree of MR achievement was. The rates of MR2 and MMR achievement were 80% and 66%, respectively. The higher Dose/BSA was associated with the lower achievement of MR2 (logit [P] = -0.085 × [Dose/BSA] + 6.61, p=0.024). Regarding DLTs, the rate of DLT occurrence was 46%. The higher the Dose/BSA of dasatinib, the greater the occurrence of DLTs was (logit [P] =-0.12 × [Dose/BSA]-7.20, p<0.001). From the first to the fourth quartile groups of Dose/BSA, the rates of MR2 achievement were 84, 92, 76 and 65%, respectively, which demonstrated a decreasing trend as Dose/BSA increases (chi-square test, p=0.016). In addition, the rates of DLT occurrence from the first to the fourth quartile groups of Dose/BSA were 13, 39, 76 and 59%, respectively, which demonstrated an increasing trend as Dose/BSA increases (chi-square test, p<0.001).
Summary/Conclusion: The higher Dose/BSA of dasatinib not only increased the chance of DLT occurrence but also decreased the probability of MR achievement. It appears necessary to administer a lower initial dose of dasatinib to an individual patient in order to achieve a higher MR as well as to keep a lower rate of DLTs in the treatment of patients with CP-CML.

PB1939

QUALITY OF LIFE IN CHRONIC MYELOID LEUKEMIA PATIENTS RECEIVING A TYROSINE KINASE INHIBITOR

G. Guclu[1], B. Aras[2], E. Gunduz[3,*]

[1]Internal Medicine, [2]Genetics, [3]Hematology, Eskisehir Osmangazi University, Eskisehir, Turkey

Background: Chronic myeloid leukemia (CML) is a disease frequently diagnosed during routine examination or blood tests and patients may remain asymptomatic for many years. Recently the standard therapy is imatinib mesylate which provides both hematological, cytogenetic and molecular remission. Second generation tyrosine kinase inhibitors (TKIs) are effective in the first line therapy but often used in resistant/intolerant patients. Treatment requires tight compliance and regular blood checks. The patient's lifetime treatment as well as regular controls affect the quality of life. Although a good quality of life with imatinib has been shown in many studies, generic imatinib is used in many countries and the data about second generation TKIs are scarce.
Aims: The aim of this study was to evaluate the quality of life of CML patients who are treated with tyrosine kinase inhibitors (generic imatinib, dasatinib and nilotinib).
Methods: A hundred and twenty patients and a healthy control group (n=20) were included after obtaining written informed consent. EORTC QLQ-CML24 and EORTC QLQ-C30 (version 3.0) scales were used to assess the quality of life. Mean age of the patients was 55±14.4 years and 68 (56%) of the patients were female. The mean duration of illness during the questionnaire was 6.7±4.5 years. Imatinib group included 72, nilotinib group included 25 and dasatinib group included 23 CML patients.
Results: Scale of satisfaction with the care received and the scale of satisfaction with the amount of information received in imatinib group were lower than dasatinib group (p=0.007). Scale of insomnia in nilotinib grup was lower than imatinib group (p=0.027). No difference was found between imatinib, nilotinib, dasatinib groups and healthy controls for all other scales in the questionnaire.
Summary/Conclusion: The quality of life in CML patients under generic imatinib, nilotinib and dasatinib were evaluated in this study. The results give information about the quality of life with generic imatinib which is used in the first line therapy of CML in many countries and add new data on the quality of life with second generation TKIs. According to the results obtained it can be concluded that the quality of life is mostly similar with healthy controls and also similar between second generation TKIs.

CARDIOVASCULAR EVENTS IN CHRONIC MYELOID LEUKEMIA PATIENTS TREATED WITH NILOTINIB

A. Bykova*, G. Gusarova, E. Chelysheva, O. Shukhov, A. Petrova, N. Tsyba, I. Nemchenko, O. Lazareva, A. Turkina

Scientific Advisory Department of Chemotherapy of Myeloproliferative disorders, National Research Center for Hematology, Moscow, Russian Federation

Background: The first reports on peripheral arterial occlusive diseases (PAOD) in Chronic Myeloid Leukemia (CML) patients (pts) treated by nilotinib appeared in 2011. Some experimental data showed direct proatherogenic actions of nilotinib (inhibition of DDR1 receptor, possible participation in pathogenic blockage of KIT and PDGFR kinases), possibility to create angiospasm. However detailed mechanisms of cardiovascular events (CVEs) emergence after exposure to nilotinib are not described.
Aims: Evaluate frequency and risk factors of CVEs emergence in CML pts treated by nilotinib.
Methods: 119 CML pts treated by nilotinib and monitored in the National Research Center for Hematology of Russia were included in the study 2007 to 2017. Male:female ratio was 45:74. Median age at the start of nilotinib treatment was 43 years (range 23-60). 67 (56.3%) pts were transferred to nilotinib due resistance to imatinib, 26 (21.8%)-due to imatinib toxicity, 8 (6.7%)-due to suboptimal response to imatinib, other-9 (7.6%); 12 pts (10%) were treated by nilotinib as first line therapy, 98 pts (82.3%) were treated by nilotinib as second line therapy after imatinib. 74 pts received 800 mg/day dose of nilotinib, 42 pts-600 mg/day, 3-400 mg/day. We evaluated risk factors (RF) of CVEs, including age, smoking, arterial hypertension presence, overweight, family history of early cardiovascular diseases, type 2 diabetes, glucose level, Lipemic index (total cholesterol and fractions, triglycerides). SCORE scale was used to evaluate RF of death due to CVEs.
Results: Before nilotinib treatment the following RF of CVEs were found: males >55 years-8 (17.7%), females >65 years-7 (9.4%), smoking-28 (23.5%), increased level of total cholesterol –39 (32.7%), overweight-34 (28.6%), hyperglycemia-12 (10%), family history of early CVEs-6 (5%), arterial hypertension-29 (39.5%), type 2 diabetes-8 (6.7%). SCORE distribution was as follows: low risk-64, moderate-18, high-8, very high-11, no data-18. In nilotinib treated pts at 14 (11.7%) (9 males (20%) and 5 females (6.8%)) the following CVEs were observed: Acute Cerebrovascular Event (ACE)-7 (5.8%), PAOD-2 (1.7%), first time observed angina pectoris-5 (4.2%). 13 of 14 of the pts mentioned above (92.8%) had a high risk according to SCORE scale before nilotinib treatment. Transfer to other tyrosine

kinase inhibitor (TKI)-18 (15%): dasatinib-12, bosutinib-2, ponatinib-1, imatinib-1, PF114-2; observation without treatment-29 (24%). 12 pts (10%) died, of which 8 (6.7%)-due to disease progression, 4 (3.4%)-due to CVEs, 2 (1.7%)-due to nilotinib treatment. 60 pts (50.4%) continue nilotinib treatment with observation median of 52.6 months (1-135.8).

Table 1.

Table 1. Distribution of patients with cardiovascular events by gender, age, risk of SCORE, and duration of therapy with nilotinib

Patients	Gender	Age, years		SCORE	Duration of treatment with nilotinib before CVS, months
		Start of nilotinib treatment	CVEs		
O.A.D.	M	55	58	high	58
S.O.P.	M	49	50	high	15
M.A.Z.	F	25	30	low	60
S.N.B.	M	54	54	high	1
V.C.D.	M	47	49	high	21
V.K.M.	F	68	69	high	12
A.N.G.	M	28	37	high	108
A.M.F.	M	66	68	high	19
I.E.M.	F	62	63	high	15
E.P.K.	F	50	52	high	24
V.M.T.	M	43	49	high	72
I.T.B.	F	78	83	high	60
A.A.S.	M	67	71	high	48
Y.S.L.	M	52	59	high	74

males - 9 (> 55 years - 3), females - 5 (> 65 years - 2)

Summary/Conclusion: Combination of obtained data allows to propose that nilotinib can be an additional factor of accelerated development of atherosclerosis leading to various CVEs. It cannot be excluded that CVEs emergence can be linked to nilotinib dose as most pts with CVEs received maximum possible dose-800 mg/day, apart from 3 pts taking lesser dose (2-600 mg/day, 1-400 mg/day). All pts with observed CVEs, excluding one, had a high risk of CVEs in accordance with SCORE scale. Taking into account possible correlation of CVEs frequency in nilotinib treated pts with high risk in accordance with SCORE scale it is recommended to estimate RF during screening to prevent CVEs emergence. At increased risk of CVEs emergence it is recommended to correct RF, which can be modified, decrease nilotinib dose or transfer to other TKI.

PB1941

MORE THAN 10-YEARS SURVIVORS WITH CHRONIC MYELOID LEUKEMIA WITHOUT ANY MOLECULAR RESPONSE-REAL LIFE EVIDENCE FROM A SINGLE INSTITUTION

G. Balatzenko[1,*], K. Ignatova[2], B. Spassov[2], S. Ivanova[1], J. Stoyanova[2], A. Lilova[2], V. Stoeva[2], Y. Petrov[3], E. Hadjiev[4], G. Tsvetkova[5], M. Guenova[6]

[1]Laboratory of Cytogenetics and Molecular Biology, [2]Department of Clinical Hematology, [3]Department of hematopoietic stem cells transplantation, National Specialized Hospital for Active Treatment of Hematological Diseases, [4]Clinic of Hematology, Medical University Sofia, Faculty of Medicine, Department of Internal Diseases, UMHAT Alexandrovska, [5]Clinic of Hematology, Medical University Sofia, Faculty of Medicine, Department of Internal Diseases, UMHAT Alexandrovska, [6]Laboratory of Hematopathology and Immunology, National Specialized Hospital for Active Treatment of Hematological Diseases, Sofia, Bulgaria

Background: The extreme effectiveness of tyrosine kinase inhibitors (TKI) has dramatically changed the clinical course and outcome of chronic myeloid leukemia (CML) patients (pts). Generally, the achievement of optimal molecular response (MR) predicts close to normal survival. In contrast, pts who fail to respond to TKI have an inferior prognosis. Whether long-term survival is possible in pts resistant to all used TKIs, and if the absence of MR is inevitably associated with a fatal outcome is not well determined.
Aims: To determine the proportion of CML pts treated with TKIs without any molecular response among more than 10-years survivors.
Methods: We retrieved 340 CML pts (168 females and 172 males; mean age of 521±16.4 years), who were diagnosed between 1998 and 2008, with a follow-up of at least 10 years after the diagnosis in the hospital records of the National Specialized Hospital for Active Treatment of Hematological Diseases-Sofia, Bulgaria. Pts were treated with chemotherapy, interferon alpha and/or by TKI. Response to therapy was evaluated according to the standard criteria. Molecular monitoring was carried-out initially by nested primers RT-PCR, afterwards by manual quantitative RT-PCR, and since 2012 by GenExpert (Cepheid) platform.
Results: In total 88/340 pts had ≥10-years survival, including 24 who achieved MR5.0 (27.3%); 13 MR4.5 (14.8%); 8 MR4 (9.1%); 19 MR3.0 (21.6%). No MR was found in the remaining 24 pts (27.3%). All refractory pts received at least 3 different TKIs with or without preceding chemotherapy or interferon alpha. All pts expressed typical *BCR-ABL1* mRNAs (13 with b3a2; 11 with b2a2), and all were diagnosed in chronic phase except one who presented in accelerated phase. The mean leukocyte count was 153.9±82.7x10^9/l; platelet count 629.9±405.8x10^9/l; and hemoglobin 125.5±30.1 g/l. All pts with available records were EUTOS score low risk. No significant differences in the main clinical and laboratory features between pts with or without MR were seen. All 24 pts achieved complete hematological response without any MR, with only a transient 1 log reduction of the *BCR-ABL1* level after the 2nd line TKI initiation in 2 of them. T315I *ABL1* mutation was found in only 1/24 (4.2%) case. During the whole period of observation, 6 (27.3%) nonresponders developed ≥1 blast crisis, while none of the pts with an achieved MR progressed. In terms of survival, 8 of the non-responders died 10-18 years after diagnosis. The remaining 16 are still alive 10-19 years after the onset.
Summary/Conclusion: Our results suggest that long-term survival might be observed in some low risk CML pts who achieved hematological response, in the absence of any molecular response to several lines of TKIs. A possible role of variations in the biology of the disease and/or a certain sensitizing effect of the preceding therapy at least in some of the pts can be speculated. Additional studies are warranted to elucidate the mechanisms underlying this observation as well as to search for additional indicators for prediction of outcomes.

MATHEMATICAL MODELLING REVEALS THE POTENTIAL FOR CONSIDERABLE DOSE REDUCTIONS IN TYROSINE KINASE INHIBITOR TREATED CHRONIC MYELOID LEUKEMIA

I. Roeder[1,2,*], A.C. Fassoni[3], C. Baldow[1], I. Glauche[1]

[1]Institute for Medical Informatics and Biometry, Faculty of Medicine, Technische Universität Dresden, [2]Data and Trial Management Unit, National Center for Tumor Diseases (NCT), Partner Site Dresden, Dresden, Germany, [3]Instituto de Matemática e Computação, Universidade Federal de Itajubá, Itajubá, Brazil

Background: The availability of tyrosine kinase inhibitors (TKIs) has revolutionized Chronic Myeloid Leukemia (CML) therapy. However, permanent control of the disease requires continuing and potentially life-long TKI therapy. While TKI cessation appeared as a safe option for about half of the optimally responding patients, a systematic assessment of the long-term effects of TKI dose de-escalation is missing.
Aims: It is our aim to theoretically study quantitative effects of TKI dose de-escalation as a potential alternative treatment option for patients with good treatment response.
Methods: We use a mathematical model (applying ordinary differential equations) to analyze and consistently describe response data of TKI-treated CML patients from independent clinical trials. The model describes CML as a clonal competition process of normal and leukemic cells that is modulated by the TKI effect. It allows us to estimate patient-specific parameters that describe cell cycle activation and de-activation of leukemic stem/progenitor cells as well as the TKI-induced kill of leukemic cells.
Results: Our analysis reveals that the TKI-induced long-term decline in CML tumor load is limited by the activation of quiescent leukemic stem cells. Based on this finding we suggest dose de-escalation schedules in which the treatment intensity can be substantially reduced without altering the long-term leukemic stem cell response. We also suggest a step-wise dose alteration to identify optimal, patient-specific TKI doses.
Summary/Conclusion: Our analysis provides strong theoretical evidence that TKI dose de-escalation does not lead to a reduction of long-term treatment efficiency in most patients. We demonstrate that continuous *BCR-ABL1* monitoring allows to provide patient-specific predictions of an optimal (reduced) TKI-dose that does not decrease the anti-leukemic effect on residual leukemic stem cells. We make the predictions that dose halving might be safe for the majority of patients and that a longer treatment with a reduced dose is more efficient than the same cumulative dose applied in a shorter period. The model results are consistent with the interim analysis of the DESTINY trial, which studies dosage-halving in CML patients in sustained remission, and it provides clinically testable predictions. Our results reveal a currently unutilized clinical potential of dose de-escalation in long-term CML treatment to reduce treatment-related side effects and therapy costs.

EVALUATION OF NK CELLS IN CHRONIC MYELOID LEUKEMIA PATIENTS: CORRELATION WITH RESPONSE TO TREATMENT

I. Attolico*, E. Pacciante, L. Impera, A. Minervini, L. Anelli, A. Zagaria,

P. Carluccio, A. Ricco, A.V. Russo Rossi, F. Albano

Ematologia con Trapianto, A.O. Policlinico di Bari, Bari, Italy

Background: Chronic myeloid leukemia (CML) is characterized by a reciprocal chromosomal translocation between chromosomes 9 and 22 [t(9;22)], producing the Bcr-Abl oncogene. Tyrosine kinase inhibitors (TKIs) represent the standard of care for CML patients (pts) through a direct oncokinase inhibition and well characterized immunomodulatory effects on T and NK cells. The main treatment goal is the achievement of deep molecular response (DMR), which makes disease progression highly unlikely and may even trigger discontinuation of TKIs. In recent years immunological factors are increasingly acknowledged as important variables being linked to achievement of DMR as well as maintenance of treatment-free remission in patients upon TKI discontinuation. NK cells are dysfunctional in CP CML patients at diagnosis and NK cell numbers among lymphocytes are reduced, worsening with disease progression to advanced and blast crisis phase CML.
Aims: We studied lymphocytes subsets, particularly NK cells number, in CML pts at diagnosis and at attainment of molecular response, to evaluate variations in NK cells number during the course of the disease.
Methods: 81 patients (54 M, 27 F; median age: 59, range: 19-86) were evaluated. 16 pts were in Chronic Phase (CP) at diagnosis, 23 in MR3, 40 in MR4/MR4.5, 2 were resistant to TKIs. 21 pts were studied at diagnosis and at achievement of Major or Deep Molecular Response (MMR/DMR). Flow cytometry analysis was performed on peripheral blood samples using the following antibodies: CD45, CD3, CD16, CD56, CD4, CD8, CD19. Samples were acquired on the FACS CANTO II (BD Bioscences) cytometer and analyzed with BCANTO software using an immunological gate (SSC/CD45) to select lymphocytes.
Results: When we studied lymphocytes subsets at a single timepoint in all the pts, we observed a significantly lower number of NK cells in pts evaluated at diagnosis (median: 13,5%, range: 3-35%) than in pts who were in MMR (median: 17%, range: 9-45%) or DMR (median:19%, range: 12-49%). In 2 pts resistant to TKIs NK values were respectively 2% and 3%. In 21 pts analyzed at diagnosis and at achievement of MMR (12 pts) and DMR (8 pts), we observed a progressive increase in NK number during the course of the disease, along with a progressive reduction of BCR-ABL transcript.
Summary/Conclusion: An increased percentage of NK at diagnosis seems to correlate with a faster achievement of MMR or DMR. Our data suggest a better prognosis for all patients maintaining an higher percentage of NK during the course of the disease. Further analysis should be made considering the effect of different TKIs on the immunological state of each patient.

NILOTINIB IN 161 PATIENTS WITH CHRONIC MYELOID LEUKEMIA IN CHRONIC PHASE AFTER IMATINIB RESISTANCE OR INTOLERANCE: "LA RAZA" NATIONAL MEDICAL CENTER EXPERIENCE

M. Ayala[1,*], D. Moreno-Lorenzana[2], J. Domínguez[3], E.J. Cordova[4], X. Aquino[3], A. Chavez-Gonzalez[2]

[1]Hematology & BMT Unit, Specialties Hospital, Nacional Medical Center "La Raza", [2]Oncology Research Unit, Oncology Hospital, National Medical Center, Mexican Institute for Social Security, [3]Grupo Consulmed, [4]Immunogenomics and Metabolics Disease Laboratory, Instituto Nacional de Medicina Genómica, México, Mexico

Background: The arrival of the second-generation (2ndG) tyrosine kinase inhibitors (TKIs) improved a significant percentage of patients with chronic myeloid leukemia in chronic phase (CML-CP) after imatinib resistance or intolerance, increasing disease survival.
Aims: The primary endpoint of this open study was to determine complete cytigenetic response (CCyR) and major molecular response (MMR) rate in patients treated with nilotinib, at 6 and 12 months respectively. Secondary objectives were to determine the OS, PFS, and EFS, as well as establishing nilotinib safety profile.
Methods: A prospective, open label, single-center study was undertaken to examine the clinical characteristics, cytogenetic and molecular response rates, overall survival, progression-free survival, and event-free survival of patients with CML-CP treated with nilotinib as a second or third-line therapy at "La Raza" National Medical Center.
Results: Of the 161 CML-CP patients included in this analysis, 98.47% were imatinib resistant and 1.53% were imatinib intolerant. The median age of the individuals was 46 years, with a median CML duration of 76 months, and a median duration of prior imatinib therapy of 29.5 months. Overall, 81% of the patients treated with nilotinib achieved a durable complete cytogenetic response (CCyR), which dropped to 71% by excluding patients who had a CCyR at baseline cytogenetic analysis. Moreover, 62% of the individuals achieved a major molecular response (MMR) at 18 months. Among the 161 nilotinib-treated patients; 88.2% were alive and 11.8% died. The median duration of nilotinib therapy for all treated patients was 46 months. The overall survival at 48 months was 92%. Adverse events were mostly moderate, transitory, and manageable.

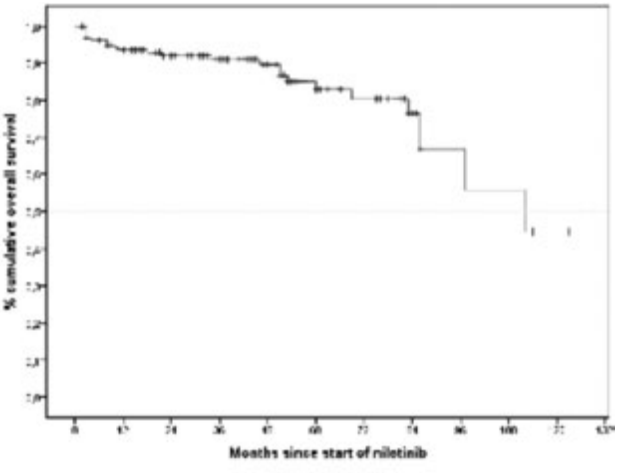

Figure 1.

Summary/Conclusion: This study shows that nilotinib is effective and can provide favorable long-term benefits for CML-CP patients who are resistant or intolerant to imatinib. Furthermore, nilotinib had a manageable safety profile.

PB1945

EVALUATION OF THE CEPHEID XPERT® BCR-ABL ULTRA ASSAY× IN CLINICAL SPECIMENS IN COMPARISON TO THE QIAGEN® IPSOGEN BCR-ABL1 MBCR IS-MMR ASSAY

S. Amar[1], G.-J. Day[2,*], E. Manor[1]

[1]Human Genetic Institute, Soroka University Medical Center, Beer-Sheva, Israel, [2]Oncology, R&D, Cepheid, Sunnyvale, United States

Background: Monitoring BCR-ABL transcript levels in peripheral whole blood (WB) of patients on tyrosine kinase inhibitor (TKI) therapy using real-time quantitative PCR (RT-qPCR) is standard of care in the management of Chronic Myeloid Leukemia (CML). Xpert® BCR-ABL Ultra (Ultra) ¥, a cartridge-based assay for use on the GeneXpert Instrument system, automates and standardizes the RT-qPCR process by integrating RNA extraction, cDNA synthesis, target amplification, detection and quantification directly from specimens in less than 2 hours. Using a lysate prepared from 4mL whole blood (WB) resulting in an effective WB input volume of 600µL, Ultra reproducibly achieves molecular response (MR) sensitivity to 4.5 logs below baseline (MR 4.5, defined as BCR-ABL1 *IS* ≤0.0032%) per the WHO International Scale (*IS*). Sample prep procedures were developed for cases where a high white blood cell count (WBCC) is known or is suspected, or when repeat testing is needed for Invalids with ABL Ct<10, allowing the use of Ultra with various input sample volume for WB or bone barrow (BM) in a wide variety of clinical situations.
Aims: We sought to evaluate the automated Ultra assay with various input sample volume. The Qiagen® psogen BCR-ABL1 Mbcr *IS*-MMR manual real-time PCR assay (*IS*-MMR), a copy number based standardization assay, was compared with Ultra in terms of assay sensitivity, concordance and classification of molecular responses.
Methods: Thirty CML specimens with%BCR-ABL/ABL (*IS*) between 100% and 0% were evaluated in WB or BM. Based on the EUTOS criteria for method comparison, acceptable concordance between two assays is defined as achieving 2 out of 3 required benchmarks: 1) ≥50% of samples within 2-fold range, 2) ≥75% within 3-fold range, and/or 3) ≥90% within 5-fold range. A linear regression analysis and an overall reporting bias analysis using the Bland-Altman model were evaluated for comparison.
Results: Among 30 CML specimens evaluated, 25 were detected by both assays with 13 identified between 100% *IS* and 0.1% *IS*, and 12 between 1% *IS* and ≤0.01% *IS* with 100% agreement to the *IS*-MMR assay (Table 1). Five specimens determined as negative by Ultra were also identified as negative by *IS*-MMR. The concordance analysis between the two assays exceeded the EUTOS criteria with 19/25 (76%), 24/25 (96%), and 24/25 (96%) falling within a 2-fold range, a 3-fold range and a 5-fold range, respectively (Table 1). Linear regression analysis showed good correlation

between two assays (R^2=0.9811; N=25) (Fig.1A). In addition, an overall bias of -0.06 (~1.15 fold) was derived using the Bland-Altman model, suggesting high concordance in% *IS* reporting between two assays across the assay dynamic range (Fig.1B).

Table 1. Concordance analysis between Ultra and *IS*-MMR per the EUTOS Criteria

Transcript Level %IS (MR)	Number of Specimens		Fold Difference (Ultra/IS-MMR)				Total
	IS-MMR	Ultra	≤2-fold (0.5-2)	≤3-fold (0.33-3)	≤5-fold (0.2-5)	>5-fold (<0.2 or >5)	
100 - 0.1 (MR0 – MR3)	13	13	11	13	13	0	13
0.1 - ≤0.01 (MR3 – <MR4)	12	12	8	11	11	1	12
Agreement	25/25 (100%)		19	24	24	1	25
Percent			76% (19/25)	96% (24/25)	96% (24/25)	4% (1/25)	100% (25/25)
Benchmarks per the EUTOS Criteria			≥50%	≥75%	≥90%	NA	NA

Fig. 1. High concordance observed between Xpert® BCR-ABL Ultra and Qiagen IS-MMR with various whole blood or bone marrow sample input volume

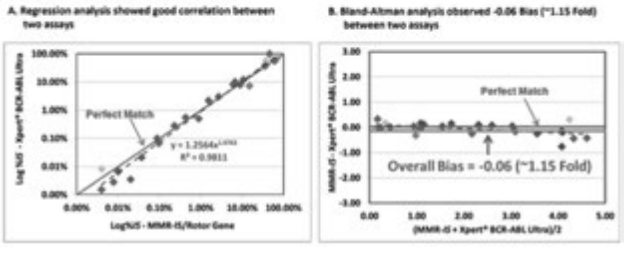

Figure 1.

Summary/Conclusion: Good concordance between Ultra and *IS*-MMR assays was achieved in WB and BM for all three benchmarks per the EUTOS criteria with good correlation observed in the linear regression analysis and using the Bland-Altman model. The Ultra assay demonstrated the ability to detect BCR-ABL1 transcripts in patients with MR 4.5 or greater reduction, thus achieving sufficient sensitivity for use in monitoring CML patients under TKI treatment. ˣCE-IVD; *in vitro* diagnostic medical device. May not be available in all countries. Not available in the United States.

PB1946

CHRONIC MYELOID LEUKEMIA WITH ISOLATED THROMBOCYTOSIS WITHOUT SIGNIFICANT LEUKOCYTOSIS IS A SUBTYPE OF CHRONIC MYELOID LEUKEMIA WITH DISTINCT DISEASE CHARACTERISTICS

Y. Sugimoto[1,*], K. Ohishi[1,2], M. Masuya[1], N. Katayama[1]

[1]Hematology & Oncology, Mie University, [2]Blood Transfusion Service, Mie University Hospital, Tsu, Mie, Japan

Background: Chronic myeloid leukemia (CML) is a myeloproliferative neoplasm which commonly manifests with neutrophilic leukocytosis in a chronic phase of the disease. We have experienced two young female CML with more than 3,000x10^9/L platelet count without significant leukocytosis. Although their clinical features suggested essential thrombocythemia (ET), they were diagnosed as CML due to the presence of Philadelphia (Ph) chromosome. Our cases together with other cases in the literature indicated that CML with remarkable thrombocytosis without significant leukocytosis (CML-IT) may have some common clinical characteristics.
Aims: We attempted to define common clinical characteristics in CML-IT, comparing with typical CML and ET.
Methods: We reviewed the literature to compile and summarize reported cases of CML-IT. We defined marked thrombocytosis as a platelet count more than 1,000x10^9/L, and normal or slightly elevated white blood cell (WBC) count as a WBC count less than 12.0x10^9/L. Clinical data of ET patients with remarkable thrombocytosis without significant leukocytosis in our hospital was also collected and compared with those of CML-IT.
Results: Our CML-IT cases were both in their mid-thirties at diagnosis. Basophils were increased, but immature myeloid cells were not detected in PB. Their von Willebrand factor ristocetin cofactors were below 30%. *JAK2* V617F, *CALR* exon 9, and *MPL* exon 10 mutation analyses were performed and confirmed to be unmutated. Their bone marrow histology exhibited marked megakaryocytic hyperplasia, and most of megakaryocytes were small and hypolobulated or unilobulated. These features were dissimilar to bone marrow histopathological findings in ET. Although Sokal score was high in both of them, deep molecular response was obtained within 2 years with tyrosine kinase inhibitor (TKI) treatment. We found 26 cases of CML-IT in the literatures and analyzed total 28 cases of CML-IT including our two cases. Most of them were female (3 males and 25 females), and the median age was 43 years old. Neutrophil alkaline phosphatase (NAP) score was decreased in chronic phase CML in general, but it was normal or increased in all 12 CML-IT. Immature myeloid cells were not detected in peripheral blood (PB) in 18 out of 20 CML-IT as opposed to those in typical CML. G-banding karyotype of bone marrow cells showed that Ph clone was below 19/20 in 10 cases out of 12 CML-IT. 8 cases were treated with TKI, and 7 out of 8 cases obtained complete cytogenetic response at 3 months. 25 cases of ET with the similar laboratory data with CML-IT cohort were found in our hospital. This ET cohort included 11 males and 14 females. Mutational analyses revealed 16 cases with *CALR* mutation, 4 cases with *JAK2* V617F mutation, and 1 case with *MPL* S505N mutation. As was the case with CML-IT, severe splenomegaly and immature myeloid cells in PB were not seen in this ET cohort. However, basophilia beyond the upper limits of normal range was not detected in ET cohort. NAP score was low in all of tested cases. These two clinical findings were different from clinical characters observed in patients with CML-IT.
Summary/Conclusion: Our cases together with other cases in the literature suggest that there is a subgroup of CML which exhibits hematologic findings similar to those in ET. Although they might be misdiagnosed as ET, laboratory findings with normal or high NAP score and basophilia may be useful to differentiate between CML-IT and ET. Further studies are warranted to better understand the clinical characteristics and molecular mechanism of CML-IT.

EARLY AND SUSTAINED DEEP MOLECULAR RESPONSE OF NILOTINIB AS A FRONTLINE THERAPY IN HIGH SOKAL RISK CML PATIENTS

U. Zaidi*, B. Kaleem, M. Borhany, S. Maqsood, N. Fatima, G. Sufaida, T. Shamsi

Haematology, National Institute of Blood Diseases and Bone Marrow Transplantation, Karachi, Pakistan

Background: Nilotinib, a second-generation tyrosine kinase inhibitor, has shown faster and deeper molecular responses when used as initial therapy in chronic phase chronic myeloid leukemia (CML). Data on efficacy and safety of Nilotinib in Asian population, particularly from Pakistan is scarce.
Aims: We aimed to determine the molecular response to Nilotinib and its safety profile in our population of chronic phase CML patients.
Methods: This single arm, non-randomized clinical trial was conducted among 138 newly diagnosed CML patients presented in chronic phase. All patients received Nilotinib 600 mg per day. The haematological and molecular response was assessed at 3 and 6 months respectively and thereafter at 6 monthly intervals. Moreover, event free survival (EFS), transformation free survival (TFS), overall survival (OS) and adverse events were also observed at long term analysis.
Results: The cumulative incidence of major molecular response (MMR) was 86% and deep molecular response (DMR *i.e.* MR 4.0 and MR 4.5) was 39%. Early MMR and DMR at 6 months of therapy were achieved by 71% and 32% patients respectively. Two- year EFS, TFS and OS rates for the whole group were 93%, 95%, and 97%, respectively. At median follow up of 29 months, 75% and 45% of patients were able to sustain MMR and DMR respectively. 50% patients had a high Sokal score at diagnosis. Adverse events were mainly weight gain in 29% and myelosuppression in 15% of patients.
Summary/Conclusion: Our results show high efficacy and safety of Nilotinib in both high and low Sokal risk CML patients.

PB1948

REAL-WORD DATA FROM LONG TERM FOLLOW-UP OF IMATINIB INITIALLY TREATED CHRONIC MYELOID LEUKEMIA PATIENTS

I. Cojbasic[1,2,*], L. Macukanovic-Golubovic[1,2], I. Tijanic[1,2]

[1]Faculty of Medicine, University of Nis, [2]Clinic of Hematology and Clinical Immunology, Clinical Center Nis, Serbia, Nis, Serbia

Background: The introduction of the tyrosine kinase inhibitors(TKIs) into clinical practice has strikingly improved survival and remission rates for chronic phase-chronic myeloid leukemia(CP-CML) patients. An emerging goal of TKIs therapy is to achieve sustained deep molecular response. It has been consistently shown that early molecular response is associated with

positive long-term outcome concerning overall survival and progression-free survival in CML patients.
Aims: The aim of this study was to investigate long-term outcomes regarding remission rates and survival in unselected group of CP-CML patients initially treated with imatinib.
Methods: This is a retrospective analysis single centre database of CP-CML patients treated with first-line imatinib 400mg daily since diagnosis and followed between August 2006 and August 2017. Patients have been analysed in intention to treat. The chronic, accelerated or blastic disease phase(CP, AP, BP) were defined according to the ELN criteria. The risk scores were calculated according to the Sokal, Euro and EUTOS formulations. Cytogenetic and molecular responses were defined according to ELN definitions and followed the procedures as described elsewhere. Cumulative incidences of treatment response were calculated under consideration of competing risks defined as progression of disease to AP, BP or death. From date of imatinib initiation, overall survival(OS) was calculated until death at any time and for any reason; progression-free survival(PFS) was calculated until progression to AP or BC at any time; event-free survival(EFS) was calculated until death, progression to AP or BP, ELN failure on imatinib or imatinib treatment discontinuation for any cause.
Results: In total 102 patients were eligible for analysis, with a median duration of therapy of 58.8(6-132) months, of which 54(52.9%) were female, with median age of 55.3(18-78) years at imatinib initiation. EUTOS score was high in 16.7% of patients. The cumulative incidence of CCyR was 69.6%(95% Cl: 66-75%) at 12 months and 82.5%(95% Cl: 79-85%) at 5 years. The cumulative incidence of MMR was 48%(95% Cl: 45-52%) of evaluable patients at 12 months, and 73.3%(95% Cl: 70-76%) at 5 years. The cumulative incidence of MR4 was 27.5%(95% Cl: 24-32%) at 24 months and 56.9%(95% Cl: 53-59%) at 5 years. Median-time to achieve MMR and MR4.0 was 1.7 and 2.8 years respectively. In the multivariate Cox model analysis, MMR at 12 months was predictive for PFS(p=0.001) and OS(p=0.001) but not for EFS(p=0.271), unlike that MR4 at 24 months was predictive for EFS(p=0.003) and PFS(p=0.011) but not for OS(p=0.505). The estimated EFS rates were 76% at 2 years, 60% at 5 years and 45% at 8 years, PFS rates were 97.1% at 2 years, 95.1% at 5 years and 92.2% at 8 years, OS rates were 98% at 2 years, 87.3% at 5 years and 82.4% at 8 years. At last follow-up, after a median of 64.5(6-132) months, 68(66.7%) patients were still on imatinib, while 25(24.5%) have been switched to 2nd TKIs nilotinib for resistance in 19(76%) or intolerance in 6(24%) cases. Overall, at latest follow-up, 16.7% patients died, of which 47.1% because of CML progression and 52.9% from other causes.
Summary/Conclusion: Analysis of this CML patients' cohort initially treated with imatinib, consistently has been confirming high rates of remission and survival and low rates of disease progression. Subsequently, imatinib has been continuing to provide an excellent long-term treatment responses and survival outcome because more than half of patients achieved a stable deep molecular response that gives the opportunity for treatment-free strategy.

Background: Normally, information regarding efficacy of treatments is obtained through clinical trials which are characterized by their strict inclusion and exclusion criteria. In real life, results depend on the relationship between the physician and the patient and on the selection of first and subsequent lines of treatment for patients who show intolerance or resistance to TKI treatment.
Aims: TKI treatment description results among TKI patients with CML from the RALMC in real life: Overall survival rates (OS) as it relates with leukemia (LRS), progression and event free survival (PFS and EFS). Rates of discontinuation due to inefficacy and intolerance. To compare effectiveness and security among imatinib and 2GTKI (nilotinib and dasatinib).
Methods: Retrospective descriptive analysis of patients from the RALMC with clinical and therapeutic follow-up since January 2002 to December 2016. Analysis of survival rates through Kaplan-Meier method, distinguishing among OS: time span since diagnosis until death due to any cause; LRS: time span since diagnosis until dead due to a cause connected to CML; PFS: time span since diagnosis until progression to AP or BC or death and EFS: time span since diagnosis until death due to any cause, progression of illness or change of treatment on first line due to inefficacy or intolerance.
Results: 505 patients, 279 males (55.2%), 104 (20.6%) of whom were over 70 years. 427 (84.6%) began on Imatinib, 46 (9.1%) on Nilotinib, and 32 (6.3%) on Dasatinib. 131 patients (30.7%) with imatinib in first-line changed treatment: 46 (10.8%) due to intolerance and 85 (19.9%) due to inefficacy. 11 patients with 2GTKI (14.1%) changed treatmente too: 6 (7.7%) due to intolerance and 5 (6.4%) due to inefficacy. 21 patients (4.2%) progressed to advanced phases: 14 (2.8%) to BC and 7 (1.4%) to AP. 63 patients (12.5%) died during the follow-up. 15 (23.8%) due to causes related to CML and 48 (76.2%) due to causes not directly related to CML. 49 patients over 70 (47.1%) died during the follow-up: 41 (83.7%) due to causes not related to CML.

Table 1.

Global series	OS	LRS	PFS	EFS
5 years	92.9%	98.3%	91.2%	69.7%
10 years	85.4%	97.2%	82.9%	57.6%

OS, PFS and EFS are higher among patients treated with 2GTKI vs Imatinib to 5 years (98.6% vs 81.6%; 97.2% vs 80.5%; 84.7% vs 59.8%, p=0.002).

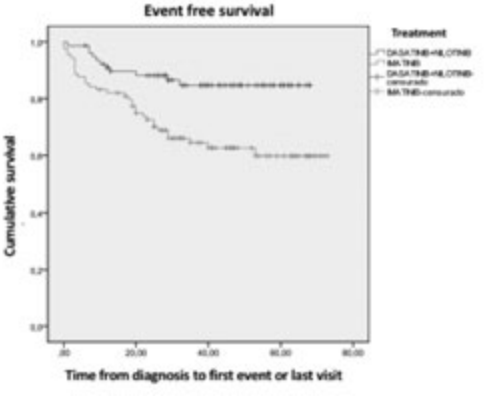

Figure 1.

Summary/Conclusion: Patients from RALMC present high OS rates and death causes are not related directly with the illness, independently of time of diagnosis. Patients treated on first line with 2GTKI present better OS, PFS and EFS rates than those treated with Imatinib. While these results are limited in our series: young patients and high risk patients begin their treatment on 2GTKI whereas older and with low-risk prognostication begin their treatment on Imatinib. Mean age for patients treated with Imatinib was almost 10 years older than that of patients treated with 2GTKI, with three times more patients over 70 years old being treated with Imatinib than with 2GTKI (27% *vs* 10.3%).

PB1950

INTERDISCIPLINARY APPROACH FOR THE MANAGEMENT OF CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH CHRONIC MYELOID LEUKEMIA

J. Badiola[1,*], J.M. Puerta-Puerta[1], R. Roa-Chamorro[2], F. Jaén-Águila[2], J.D. Mediavilla-García[2], M. Jurado-Chacón[1]

[1]Hematology, [2]Internal Medicine, Hospital Virgen de las Nieves, Granada, Spain

Background: The introduction of the tyrosine kinase inhibitors (TKI) for the treatment of chronic myeloid leukaemia (CML) has been a paradigm shift in the prognosis of the patients who now achieve near-normal life expectancy. This formidable improvement notwithstanding, there is concern

about TKI-associated vascular adverse events (VAE) and the management of cardiovascular risk factors (CVRF) still remains to be a challenge in these patients. We report on the creation of an interdisciplinary workgroup between the departments of Haematology and Internal Medicine for the comprehensive assessment of CVRF in CML patients treated with TKI.
Aims: To describe the protocol used in the unit, to identify previous and post-assessment CVRF and to detect vascular subclinical disease and VAE.
Methods: Since September 2016, 61 CML patients with TKI treatment were evaluated in the cardiovascular risk unit. The following data were collected: personal and familiar history, clinical history and physical exploration, basic analytical tests and specific complementary tests (ankle-brachial index - ABI), pulse wave velocity (PWV) and ambulatory blood pressure monitoring (ABPM).
Results: Of the 61 patients, 54.4% received imatinib, 42.6% nilotinib and 24.6% dasatinib, with an average treatment duration of 92, 52 and 35 months respectively. The average age was 58 years and 63.9% were males. The CVRF identified before the first evaluation in the cardiovascular risk unit are shown in the Table 1. We found that 28.5% of the patients had poor control of blood pressure as measured with ABPM, 10.7% had poor glycaemic control (glycated haemoglobin greater than 6.5%) and 21.6% ≥stage 3 renal insufficiency. In 35% of the patients, total cholesterol was greater than 200mg/dl, in 36.6% LDL cholesterol was >130mg/dl, in 23.3% triglycerides levels were >150mg/dl and in 17.2% homocysteine was >20mmol/l. With regard to vasculopathy, 10.8% of the patients had pathologic ABI. Suprinsingly, a subclinical vascular damage, as measured with PWV, was detected in a far greater percentage of the patients (24.5%). During the follow-up, we observed VAE in 18.6% of the patients, more specifically 8 peripheral arterial disease events, 2 strokes and 1 acute myocardial infarction.

Table 1. Previous CVRF.

Family history of CVRF	51.7%
Arterial hypertension	36.1%
Diabetes	13.1%
Dyslipidemia	21.3%
Previous VAE	6.6%
Renal insufficiency (≥stage 3)	3.3%

Summary/Conclusion: For an adequate control of the CVRF in CML patients, an integral multidisciplinary evaluation is mandatory. In a significant number of the patients, after the initial evaluation in the cardiovascular risk unit is carried out, there are new diagnosis of CVRF and/or poor control of such factors. The identification of these cases allows to optimize the management of CVRF and to decrease VAE. The PWV could be an optimal tool to detect subclinical endothelial damage prior to VAE and to identify those patients who might benefit from a more intensive treatment of their CVRF.

PB1951

PROGNOSTIC ROLE OF REBOUND BASOPHILIA DURING CYTOREDUCTION IN PATIENTS WITH CHRONIC MYELOID LEUKAEMIA

L. Vrablova[1,*], L. Benesova[1], B. Maiwaldova[1], T. Furst[2], I. Skoumalova[1], P. Rohon[1], K. Indrak[1], H. Urbankova[1], M. Divoka[1], E. Faber[1]

[1]Haemato-oncology department, Faculty Hospital Olomouc, [2]Faculty of Science, Palacky University, Olomouc, Czech Republic

Background: Basophilia is a frequently observed condition in chronic myeloid leukemia (CML) but its etiopathogenesis is not completely clear. Basophilia may not only be an accompanying phenomenon of CML but it may play a pathogenic role in the disease development. The role of CCL3 inflammatory chemokine produced by basophils was described in CML. We have observed **rebound basophilia (RB)**-an increase in the relative proportion of basophils in WBC differential counts (WDC) in some CML patients within the first month of cytoreduction treatment with hydroxyurea and/or imatinib. For the purpose of this study, RB was defined as an increase of one or more percent of basophils in WDC (assessed by light microscopy or counter in cases where light microscopy WDC was not available) with respect to the initial assessment before cytoreduction.
Aims: The aim was to analyze the incidence and possible prognostic role of RB.
Methods: We have retrospectively analyzed the WDC of CML patients at our institution during the first month of treatment. Overall and progression-free survival (OS, PFS) were calculated according to the Kaplan-Meier methodology, the log-rank test was used to assess the difference in survival between RB positive and RB negative patients, and the Kruskal-Wallis test were used to assess the difference in continuous variables between the two groups.
Results: We have analyzed 41 female and 63 male patients of median age of 54 years (range 20–88), the median follow-up was 3.1 years (range 3.5 months-10.9 years). There were 65 cases of RB including 7 patients who were not in the accelerated phase at diagnosis but fulfilled the criteria for CML acceleration with isolated RB over 20% during cytoreduction. Statistically significant association of RB with younger age (p=0.02) and the Sokal score (p=0.02) was documented. Spleen size (in cm below the costal margin) was significantly larger (p=0.02) in patients with RB (median=5 cm) than in patients without RB (median=0 cm) Younger patients with RB died more often after the progression of CML, while elderly patients without RB died more often due to comorbidity without CML progression. RB positive patients more frequently required the treatment with second generation tyrosine kinase inhibitors (TKI) due to the imatinib failure (38.9%) in comparison with the RB negative group (22%; p=0.06), however their response to the treatment was not compromised. We found no statistical difference in progression free survival between the RG positive and RB negative groups (63% *vs* 75%, p=0.346). The overall complete cytogenetic response rates at 6 months after treatment initiation (CCyR) were not different between the RG positive and RB negative (29% *vs* 16%, [FEpMC1] p=0.14). Patient with and without RB had similar rates of major molecular response after 12 months after treatment initiation (25% *vs* 34%, p=0.31).
Summary/Conclusion: RB may be encountered in about half of CML patients. Although RB may has been observed by many physicians, its cause is unknown. RB is associated with other CML risk features but it probably lacks an independent prognostic value. However, RB may have a role in the prognostic stratification of younger CML patients. Further experiments and studies in larger cohorts of patients are needed to reveal the causes of RB and to evaluate its possible prognostic role.
Supported by the grant of IGA_LF_2018_04.

TREATMENT- FREE REMISSION UP TO 12 YEARS. INTERIM ANALYSIS OF A REGIONAL GERMAN CML-REGISTER. (A CONTRIBUTION OF GERMAN CML-ALLIANCE)

D. Kämpfe[1,*], J. Brenn[2], T. Haverkamp[3], C. Schulte[4], H. Tesch[5], H. Stein[6]

[1]Praxis f. Hämatologie u. Onkologie, Lüdenscheid, [2]Incyte Biosciences Germany GmbH, Planegg/Martinsried, [3]Leitung Analysenbereich Molekulargenetik II, MVZ Dr. Eberhard & Partner Dortmund (GbR), Dortmund, [4]Institut für Hämatopathologie Hamburg, Dres. Tiemann, Schulte Holding GmbH, Hamburg, [5]Centrum für Hämatologie und Onkologie Bethanien, Frankfurt / M., [6]Pathodiagnostik Berlin, Berliner Referenzzentrum für Lymphom- und Hämatopathologie, Berlin, Germany

Background: Treatment-free remission (TFR) is an achievable goal for patients with chronic myeloid leukemia (CML) in the tyrosine kinase inhibitor (TKI) era. Median follow-up time in studies up to 60 month are documented very well, and stable molecular remissions (MR)>3 in approximately 50% of patients during this period are reported. Treatment conditions differ in primary therapy (type of TKI; IFNa ?) and in duration of deep molecular remission (mostly 1 to 2 years in current studies with 2nd GenTKI).
Aims: To enhance the current debate: "How to achieve TFR?" we describe 7 patients of our "real world" register, who are in TFR for at least 2 years after Imatinib (IMA) as their 1st line TKI- therapy.
Methods: Our register includes 52 CML-patients, newly diagnosed between 01/1998 and 12/2017. Median age (62,1y, 22-84y), sex ratio (m : f=1,7 : 1) and raw incidence ($1{,}1/10^5$) correspond to literature. Diagnoses are based on morphological and genetic findings of EUTOS-accredited laboratories. Ending the TKI-therapy was considered after 3 years of continuous genetic remission (MR >MR 4,5 and / or nested PCR negativity). 8 of 14 candidates finished therapy that way. 1 more patient finished 6 months after IMA in 2nd molecular remission after previous allo-transplant.
Results: After stopping TKI-therapy 7 of 9 patients (77,8%) remained in complete molecular remission. Median OS from diagnosis is 187,1 months (119-240 mo). Median duration of TFR is 59,5 months (24,5-144,5 mo). Median age (at diagnosis) was 56,9 years (40,8-69,4 ys), sex ratio (m : f) is 5 : 2. BCR-ABL transcript type E14a2 was found in 4 *vs* E13a2 in 2 patients (1x unknown), which may be different from the expected ratio in CML-CP. EUTOS risk was "high" in 3 patients; 1 of 7 was in primary accelerated phase (pAP). 1 patient got TKI after initially aggressive conventional chemotherapy and consecutive HU / IFNα ("OSHO 1995"-study) for 174 months, with interruption of IFNα for 24 months because of autoimmune thyreoiditis. Also 2 other patients received IFNα prior to TKI, 1 in combination ("CML IV" study, later in the "NICOLI" study-immediately finished

because of GUILLAIN-BARRE-like-syndrome). TKI was changed from IMA to DASA in 1 and to NILO in another case. Body mass index (BMI) of 2 patients was >30, 1 of them got IMA mainly 300 mg per day. Remarkably in 2 patients JAK2-mutation was detected (low level, but consistently), one in combination with KIT-mutation and one in a patient with splenomegaly and suspected 2nd neoplasia (CMML? MDS?) who acquired additional KRAS & CSMD1 mutations in addition to a presumably germline variant of JAK3 (p.V722I).
Summary/Conclusion: Despite limited number of patients our real life experience illustrates: 1.) TFR more than 10 years is an achievable aim, also in patients treated with IMA as a 1st line TKI and under real life conditions. 2.) Most common features of our TFR-patients were: 3-year continuing deep mol.-genetic remission (6/7) and after using IFNα (4/7). Both common features are discussed thoughtfully in the literature. Most other characteristics were heterogeneously. 3.) As recently discussed (GALE and HOCHHAUS 2018) TFR may be achieved by one or in combination of different mechanisms. This could correspond to the heterogeneous characteristics of our patients. 4.) Furthermore TFR stabilizing effect could be growth-inhibition by non-BCR-ABL-mutated subclones implying passenger mutations.

PB1953

FREQUENCY OF GATEKEEPER MUTATION IN THE NON-RESPONDING CHRONIC MYELOID LEUKEMIA PATIENTS

B. Kaleem*, S. Shahab, M. Borhany, U. Zaidi, T. Farzana, D. Zahid, T. Shamsi

Haematology, National Institute of Blood Diseases and Bone Marrow Transplantation, Karachi, Pakistan

Background: Chronic Myeloid Leukemia is a myeloproliferative disorder that results due to reciprocal translocation t(9;22)(q34.1;q11.2) leading to the formation of an oncogene. Although Imatinib proved to be revolutionary treatment wise but 20% showed resistance. Point mutations in the ABL Kinase Domain were one of the causes of the resistance of which T315I was found to be the most resilient against all Tyrosine Kinase Inhibitors (TKIs).
Aims: This study observes the frequency of T315I mutation in TKI non-responders in our population.
Methods: Patients labeled as non-responders according to European Leukemianet guidelines to the first line therapy *i.e.* Imatinib or Nilotinib at our centre were included. The blood sample was collected in an EDTA vacutainer. DNA was extracted and then analyzed for the presence of both wild type and mutant via PCR. Negative controls were healthy individuals and demographically similar to the patients.
Results: Out of 150 patients, 44 were found to be non-responders. Patients were divided into three groups on the basis of TKI administered. Imatinib (n=3), Nilotinib (n=22) and those shifted from one TKI to another (n=19). Of these, 37/44(84.1%) patients had the presence of T315I.
Summary/Conclusion: Mutational analysis in the event of resistance and prior to the shift to next generation is mandatory. The presence of mutations will tailor the further treatment plan of the patient. As in our case the presence of T315I mutation will help in counseling the patients for the stem cell transplantation and prevent their further exposure to TKIs which would be an unwanted financial and psychological burden for them.

PB1954

CHRONIC MYELOID LEUKEMIA (CML) MAY CO-EXPRESS THE P210 BCR-ABL1 AND P195 BCR-ABL1

S. Gonçalves Pereira*, F. Saraiva, L. Monteiro, M. Silva, R. Vinhas, P. Viana Baptista, S. Costa Santos, A. Lourenço, P. Ribeiro, A.R. Fernandes, A. Botelho De Sousa

Hematologia Clínica, CHLC, [2]UCIBIO, Dep. of Life Science, FCT-UNL, Lisboa, Portugal

Background: Around 95% CML pts have breakpoints in the M-bcr, which result in b2a2 (e13a2) and/or b3a2 (e14a2) fusion mRNAs, both of which are translated into the p210 BCR-ABL protein, which in turn functions as a constitutively active Tyrosine Kinase (TK) leading to alterations in cell proliferation, differentiation, adhesion, and survival. Rarely, other breakpoints can occur-p190 BCR-ABL1 protein (m-bcr) or p230 BCR-ABL1 protein (μ-bcr), respectively, e1a2 and e19a2. There are other atypical breakpoints outside these cluster regions, usually associated with an aggressive clinical course.
Aims: To document a confirmed case of the co-expression of the p210 BCR-ABL1 and p195 BCR-ABL1 proteins in a CML patient, in order to draw attention to this rare diagnosis and its aggressive clinical course.
Methods: We report the case of a previously healthy 36 year-old man, with no relevant past diseases and a one-month history of fever and night sweats, on physical examination no hepatosplenomegaly or lymphadenopathy were found. Haemoglobin was 12.9g/dl, WBC were 58300/μL (90.8% neutrophils, 1.4% eosinophils, 0% basophils, 6.5% lymphocytes, 1.3% monocytes) and platelet count was 507000/μL. Bone marrow aspiration showed 1% blasts and FISH for BCR-ABL1 was 98% positive. A diagnosis of CML was made, with a Sokal score of 0.57, Hasford 58 and EUTOS 0. The patient initiated imatinib 400mg/day and a haematological response was achieved, with no cytogenetic response at 3 months of treatment, despite an increase of the imatinib dose to 600mg at 4 months and 800mg two weeks later. Treatment was switched to bosutinib at month 9. Cytogenetic response was achieved at 7 months after bosutinib initiation.
Results: The molecular analysis showed a rare co-expression of the p210 BCR-ABL1 and p195 BCR-ABL1, attributable to an alternative splicing of the transcript arising from the M-BCR chimeric oncogene. While waiting for related-donor survey for subsequent allogeneic transplantation, at month 11 of bosutinib, the disease progressed to a lymphoid blastic crisis, presenting with pancytopenia with 61% blastemia, and 96% bone marrow lymphoblasts; p210 remained in cytogenetic response yet p195 remained FISH positive. R-HyperCVAD+dasatinib+intra-thecal chemotherapy was initiated. At the end of the 1st A cycle a complete response was documented.
Summary/Conclusion: Different transcript co-expression has been reported by others in rare cases of CML, but with p210 and p190 BCR-ABL1. This is the first report of CML co-expressing p210 and p195 BCR-ABL1. Possibly, because of the shorter transcript lacking regulatory domains, p195 is associated with a dismal prognosis. Even though this patient initially presented in a chronic phase, the p195 clone remained positive in FISH and ultimately the disease progressed to a lymphoid blastic crisis.

PB1955

DEVELOPMENT OF SAMPLE PREPARATION PROCEDURE FOR TESTING SPECIMENS WITH HIGH WHITE BLOOD CELL COUNTS FOR XPERT® BCR-ABL ULTRA×

V. Mahaffey[1], S. Amar[2], G.-J. Day[3,*], E. Manor[2], D. Viswanatha[1]

[1]Molecular Hematopathology Lab, Mayo Clinic, Rochester, United States, [2]Human Genetic Institute, Soroka University Medical Center, Beer-Sheva, Israel, [3]Oncology, R&D, Cepheid, Sunnyvale, United States

Background: Monitoring BCR-ABL transcript levels in peripheral whole blood (WB) of patients on tyrosine kinase inhibitor (TKI) therapy using real-time quantitative PCR (RT-qPCR) is standard of care in the management of Chronic Myeloid Leukemia (CML). A successful RT-qPCR reaction requires isolation of high quality RNA and optimization of the input quantity for the conversion of RNA to cDNA for accurate quantification. GeneXpert® BCR-ABL V2[YY] or Xpert® BCR-ABL Ultra (Ultra), a cartridge-based assay for use on the GeneXpert Instrument system, automates and standardizes the process in less than 2 hours. The Ultra calibration and quantification are standardized by monitoring the input RNA quality and quantity based on the cycle threshold (Ct) of the control gene ABL, which is highly correlated to the input white blood cell (WBC) number in whole blood (WB). Using a lysate prepared from 4mL WB, resulting in an effective WB input volume of 600μL, Ultra reproducibly achieves molecular response (MR) sensitivity to 4.5 logs below baseline (MR 4.5, defined as BCR-ABL1 *IS* ≤0.0032%) per the WHO International Scale (*IS*). There are, however, clinical situations where the total RNA isolated from high numbers of WBC circulating in the patient's blood or in bone marrow (BM) samples can overload the Ultra cartridge and other quantitative BCR-ABL assays, requiring subsequent dilution of the sample and retesting.
Aims: In this set of experiments, we sought to define the WBC input limits for Ultra that would predict cartridge overload, and thereby provide guidance regarding when to dilute the patient's sample in the presence of high WBC.
Methods: Serial dilutions of high or normal WBC counts (WBCCs) specimens were tested in Ultra to determine the upper and lower WBC input limits corresponded to the valid ABL Ct cutoffs of 10 and 18, respectively. Sample prep procedures were developed to allow using 50μL or lower input volume from WB, BM, or their 1st lysate with or without the WBCCs information,, and validated by testing in CML specimens with various WB or BM input volume, compared to the Qiagen® BCR-ABL1 Mbcr *IS*-MMR assay (*IS-MMR*) (Table 1).
Results: The WBC input number of ~20 million cells/mL WB corresponded to the upper limit, and ~150K cells/mL WB corresponded to the lower limit of the valid ABL Ct range for Ultra, respectively. For CML specimens with WBCCs<20 million cells/mL WB, the standard initial 4mL WB sample input yielded ABL Ct results within acceptable limits. For the WBCCs ≥20 million

cells/mL WB, reaching as high as >500 million, sample prep procedures were developed to use 50µL or lower input volume (Table 1). When the WBCC information is not available but with suspicion of high WBC yielding a very viscous 1st lysate that is hard to pipette, a 1st lysate dilution procedure was developed to allow for testing with 50µL or lower WB or BM input volume. However, for the situation where a low input sample volume, for example 50µL, was used but still yielded ABL Ct<10, then an even lower input sample volume (10µL or lower) might be used to re-test the sample (Table 1). This was validated in Ultra by testing CML specimens with various WB or BM input volume and showed high concordance when compared to the Qiagen® *IS*-MMR.

Table 1.

Table 1. Recommended input whole blood volume relative to the White blood cell counts for Ultra

		White blood cell count (million/mL whole blood)				
		<20	≥20 & < 50	≥50 & <100	≥100 & <300	≥300
Input whole blood volume	Initial testing	600µl*	50µl	25µl	10µl	5µl
	When repeat testing is needed due to an initial invalid call with the ABL Ct < 10	10 µl - 50µl	2µl** - 10µl	2µl** - 5µl	2µl**	1µl**

*Calculated WB input volume using the 1st lysate prepared from 4mL whole blood
**Calculated WB input volume using 10X pre-diluted WB with 1X PBS

Summary/Conclusion: In summary, sample prep procedures were developed in cases where high WBCC is known, or is suspected, or when repeat testing is needed for Invalids with ABL Ct<10, allowing the use of Ultra with various input sample volume for WB or BM in a wide variety of clinical situations.

PB1956

IMPROVING EUTOS SCORE SENSITIVITY BY USING SERUM ALPHA/BETA TRYPTASE-1 LEVEL IN NEWLY DIAGNOSED EGYPTIAN PATIENTS WITH CHRONIC PHASE CHRONIC MYELOID LEUKEMIA IN CORRELATION TO THE MOLECULAR MILSTONES

A. Youssef[1,*], M. Elsorady[1], M. Ayad[2], A. Abdelrahman[1]

[1]Internal medicine, hematology and BMT unit, [2]Clinical pathology department, Faculty of Medicine Alexandria university, Alexandria, Egypt

Background: The European treatment and outcome study (EUTOS), a chronic myeloid leukemia (CML) prognostic score based only on the percentage of basophils in the blood and on spleen size, was formulated and shown to have improved predictive power. The EUTOS score marks a significant advance because it provides better positive predictive values than those obtained with either of the previous scores (Sokal and Hasford) and its easy application. Moreover, it is specifically based on Imatinib-treated patients, and does not need the use of the other factors that have not been found to affect the response to Imatinib. Serum alpha/beta tryptase 1 is a novel biomarker with a prognostic significance that can be used to differentiate clonal from non clonal causes of basophilia that may affect EUTOS score sensitivity.
Aims: Testing EUTOS score in newly diagnosed CML in chrnoic phase and evaluating the addition of serum alpha beta tryptase one on the score sensitivity in correlation with the established prognostic scores (Sokal and Hasford) and molecular milestones.
Methods: 48 CML cases to 19 controls were studied with a male : female ratio 1:1 and mean age of 43.94 years. Serum α/β tryptase 1 level was measured at presentation using quantitative sandwich ELISA technique (EIAab kit catalog no: E1070h, China). Patients were recruited from hematology outpatient clinic, Alexandria faculty of medicine excluding patients in acceleration or blastic transformation. All patients were subjected to the routine clinical examination, abdominal ultrasonography, viral hepatitis and HIV screening, peripheral blood smear examination, bone marrow examination and BCR ABL 1 at diagnosis, 3 and 6 months using RQ PCR. Sokal, Hasford and EUTOS scores were calculated for each patient at presentation. EUTOST score was calculated based on the formula (serum tryptase in mg + subcostal splenic span in cm). All patients included were eligible to start frontline Imatinib treatment 400 mg daily during molecular monitoring.
Results: The results show the EUTOS score has lower sensitivity and specificity at the cut off 87 compared to 154 suggesting the higher splenic meaurements and basophilia in our study, when applying the higher cut off better predictive power was seen. With the addition of serum tryptase (EUTOST) there is a noticed increase in the sensitivity and specificity compared to EUTOS score (increased area under ROC curve). This may be explained by higher prevalence of liver disease in our sample (5 schistomiasis and 7 chronic HCV cases).

Table 1.

	EUTOST	
	rs	P
BCR-ABL at 3	0.736*	<0.001*
BCR-ABL at 6	0.830*	<0.001*
Sokal	0.829*	<0.001*
Hasford	0.715*	<0.001*
EUTOS	0.972*	<0.001*

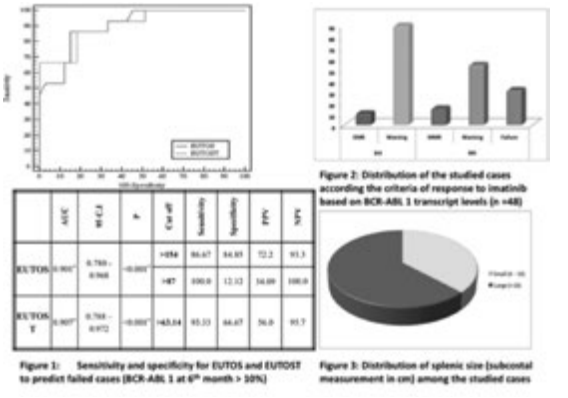

Figure 1: Sensitivity and specificity for EUTOS and EUTOST to predict failed cases (BCR-ABL 1 at 6th month > 10%)

Figure 2: Distribution of the studied cases according the criteria of response to imatinib based on BCR-ABL 1 transcript levels (n =48)

Figure 3: Distribution of splenic size (subcostal measurement in cm) among the studied cases

Figure 1.

Summary/Conclusion: EUTOS score showed high sensitivity when used with a higher cut off value 154 suggesting that the non clonal causes of basophilia and splenomegaly in the Egyptian population play a role in high risk prognostication. Besides identifying the non clonal causes of high EUTOS risk prognostication, applying serum tryptase level has improved its prognostic significance and predictive power.

PB1957

EVALUATION OF LOW LEVEL DETECTION OF MAJOR BCR-ABL1 MRNA IN CHRONIC MYELOID LEUKEMIA (DOMEST ADDITIONAL STUDY)

H. Kitamura[1,*], Y. Tabe[2], K. Tsuchiya[2], M. Yuri[2], S. Misawa[2], T. Horii[2], A. Ohsaka[2], S. Kimura[1]

[1]Division of Hematology, Respiratory Medicine and Oncology, Department of Internal Medicine, Faculty of Medicine, Saga University, Saga, [2]Department of Clinical Laboratory Medicine, Juntendo University School of Medicine, Tokyo, Japan

Background: Chronic myeloid leukemia (CML) is caused by a reciprocal translocation between chromosome 9 and 22 forming an oncogenic *BCR-ABL1* fusion gene. A *BCR-ABL1* Tyrosine kinase inhibitor (TKI) is a therapeutic agent in patients with CML. Although highly potent TKIs have been developed for deeper molecular response, about 50% of sustained DMR achieved CML patients relapse after TKI cessation. To predict the suitable time point for TKI treatment cessation, highly sensitive and specific molecular real-time quantitative polymerase chain reaction (RQ-PCR) is required to monitor minimal residual disease (MRD) levels.
Aims: In this study, we aimed to evaluate the newly developed RQ-PCR as an additional study of "The Delightedly Overcome CML Expert Stop TKI (DOMEST) trial" conducted by the DOMEST group in Japan.
Methods: In the DOMEST study, after stopping imatinib DMR was assessed by RQ-PCR in a central laboratory (BML, Tokyo, Japan). For this analysis we used residual total RNAs from 102 patient samples of DOMEST trial, which recruited CML patients in chronic phase received imatinib therapy,

reduced *BCR-ABL1* levels to undetectable levels (MR4.0) by transcription-mediated amplification (TMA), reverse transcriptase-polymerase chain reaction or RQ-PCR for over 2 years. The median age of the patients was 62 years (27-88). The percentage of the patients who had low Sokal risk scores was 57 of 102 cases (56%) and the median duration of imatinib treatment was 99.5 months (13.0-160.0).
Results: *BCR-ABL1* negativity has been confirmed by the central laboratory RQ-PCR assay at the starting time point of the DOMEST study (n=102). In 6 of these samples (6%) the new RQ-PCR assay detected *BCR-ABL1* transcripts which were confirmed by the sequencing analysis. During the MRD monitoring after imatinib cessation, the new RQ-PCR assay detected *BCR-ABL1* positivities at the same timing with the central laboratory RQ-PCR in 15 of 102 cases (15%). Correlation of IS% *BCR-ABL1*/*ABL1* between the new RQ-PCR and the central laboratory RQ-PCR assays showed a strong correlation (r=0.74, *P*=0.003). The new RQ-PCR assay detected MRD in 21 cases (21%) at the earlier timing than the central laboratory RQ-PCR assay. We further examined *BCR-ABL1* mRNA levels in these 21 samples by a commercially available ODK-1201 RQ-PCR assay kit (Otsuka Pharmaceutical Co., Tokyo, Japan), which detected the low level of *BCR-ABL1* mRNA in 14 samples (74%) and negative in 5 samples (26%) with 2 samples of not available due to the insufficient amount. No sample with *BCR-ABL1* positive by the central laboratory RQ-PCR assay and negative by the new RQ-PCR assay was observed.
Summary/Conclusion: The newly developed RQ-PCR assay has been shown to be more efficient for monitoring MRD in TKI-treated CML comparing the conventional PCR based assays. Further clinical studies of monitoring MRD in TKI-treated CML are required.

PB1958

TWELVE YEARS RESULTS OF FIRST-PHASE CHRONIC MYELOID LEUKEMIA (CML) TREATMENT WITH IMATINIB 400 MG (IMATIB*) IN 222 PATIENTS

N. Abdennebi*, F. Harieche, F. Boukhemia, M. Benakli, R. Ahmed Nacer, R.-M. Hamladji

Hematology and Bone Marrow Transplantation, Pierre and Marie Curie Center, Algiers, Algeria

Background: The classic evolution of 3-phase CML (chronic, accelerated and blast) has been revolutionized by the advent of the tyrosine kinase inhibitors leading the way to Imatinib: we are now talking about a chronic disease. From April 2005 to October 2017, 222 patients (pts) with CML in the first phase were treated with Indian Imatinib: Imatib*.
Aims: Evaluation of Imatib (Indian Imatinib).
Methods: There are 115 men and 107 women (sex ratio: 1.07) with a median age of 44 years (13-77). The molecular study by qualitative RT-PCR specified the type of transcript in 219 pts (98.6%): b2a2 at 98 pts (45%), b3a2 at 117 pts (53%), a double transcript b2a2-b3a2 at 2 pts and variant BCR-ABL at 2 pts (c3a2 and e1a2). According to Sokal classification, 129 pts (58%) are at intermediate score, 57 pts (26%) at high risk and 36 pts (16%) at low risk. According to the Eutos score, 170 pts are at low risk (77%) and 52 pts at high risk (23%). All patients were treated with Imatib *400mg after treatment with Hydroxy-Urea in 210 pts (94.5%) and *de novo* in 9 pts. It should be noted that 3 pts received pegylated interferon because of pregnancy diagnosis in the first trimester.
Results: In October 2017, 204 pts are evaluable with a median follow-up of 76 months (3-163). The response is complete hematologic in all pts and major molecular (residual disease<0.1% by quantitative RT-PCR) at 6, 12 and 24 months respectively in 80/172 pts (46.5%), 101/155 pts (65%) and 99/124 pts (80%). Primary or secondary resistance is observed in 53 pts / 204 (26%) with no RMM at least at 12 months in 26 pts, loss of RMM already obtained in 8 pts, ratio>10% at 6 months in 5 pts and hematologic relapse in 14 pts. A progression to acute leukemia is observed in 12 pts (6%) but in no pt beyond 6 years. Sixteen pts / 204 (8%) died: 11 of acutization, 4 of a probable Imatib complication and one of a non-CML cause. At 12 years old, 142pts (69.5%) are still treated with Imatib * 400 mg including 72 in RMM4 and 7 in RMM3 more than 3 years of treatment. The actuarial overall survival (OS) and event free survival (EFS) are respectively 88.6% and 77% comparable to those of the IRIS study. According to Sokal score, the OS are 100, 88 and 84.3% and the EFS are 92.8; 76.3 and 71.6% respectively for low, intermediate and high risk with only a significant difference between low and high risk. According to Eutos, the OS and EFS are not significantly different for low and high risk, they are 91 and 85.3% for OS and 78.7 and 72.6% for EFS.
Summary/Conclusion: With a 12-years decline in use, we were able to confirm that the efficacy of Imatib is comparable to that of the originator molecule with a cost ten times lower, which made it possible to treat all the pts of the Algerian territory.

PB1959

EPIDEMIOLOGY IN CHRONIC MYELOID LEUKEMIA (CML) IN ANDALUSIA (SPAIN). RESULTS FROM THE ANDALUSIAN REGISTRY OF CML (RALMC) 2002-2016

Mata-Vázquez[10], M.C. Avellaneda[11], I. Simón-Pilo[12], I. Ballesteros[13], Y. Moatassim[14], J. Oliveros[15], A. Jiménez-Velasco[8], P. López-Garrido[16]

[1]Hematology, UGC intercentros Hospital Universitario Virgen de las Nieves-Nuevo San Cecilio, Granada, [2]Hospital Universitario Virgen de la Victoria, Málaga, [3]Hospital San Juan de la Cruz, Úbeda, [4]Hematology, Complejo Hospitalario de Jaén, Jaén, [5]Hematology, Hospital de Jerez, Jerez de la Frontera, [6]Hematology, Hospital Universitario Virgen Macarena, Sevilla, [7]Hospital Torrecárdenas, Almería, [8]Hospital Regional Universitario Carlos Haya, Málaga, [9]Hematology, Hospital de Puerto Real, Puerto Real, [10]Hospital Costa del Sol, Marbella, [11]Hematology, Hospital San Agustín, Linares, [12]Hospital Virgen de Valme, Sevilla, [13]Hospital de la Axarquía, Vélez Málaga, [14]Hospital Santa Ana, Motril, [15]Hospital La Inmaculada, Huércal Overa, [16]Grupo Andaluz de LMC, Granada, Spain

Background: Despite clinical and therapeutic advances on CML, little is known about its epidemiology and there are not many publications showing results on patients' health in real life. Population registries allow to obtain information on incidence, prevalence and effectiveness of treatments; this information is usually obtained through clinical trials characterized by their strict inclusion and exclusion criteria.
Aims: To describe the epidemiological characteristics of patients with CML CP in Andalusia and to calculate the rates of incidence among patients older than 20, adjusted to the European population in order to allow for comparison with other registries.
Methods: Population-based retrospective descriptive study on real life, which analyzes the epidemiological features among patients included in RALMC since January 2002 to December 2016. In order to calculate the accumulated incidence new diagnostics were taken since January 2005 until December 2012 and in order to compare with other incidence rates, adjustments via direct rates adjustment was made, taking as reference the standard a European population sample from IARC. RALMC and its associated projects are carried out according to current Spanish legislation as well as recommendations for research projects given in the Helsinki Declaration.
Results: With a number of new diagnostics at 288 patients older than 20 in Andalusia between 2005 and 2012, accumulated incidence rates as it is adjusted to the European standard population for CML in Andalusia is of 0.97 cases out of every 100.000 inhabitants/year. Until December 2016, 505 patients have been included, 279 males (55.2%). Mean age is 55 (20-90). 104 patients (20.6%) older than 70 with a mean of global follow-up of 86 months (11-194). 275 patients (54.5%) low-risk Sokal, 166 (32.9%) intermediate risk and 63 (12.5%) high risk. Low Hasford Euro score 248 patients (49.1%), intermediate 184 (36.4%), high 54 (10.7%) and 19 unknown (3.8%) and low EUTOS score in 383 patients (75.8%), high 103 (20.4%) and 19 unknown (3.8%).

Table 1.

BASELINE CHARACTERISTICS OF THE STUDY RALMC POPULATION (N=505 PATIENTS)

	Sex	Age		Sokal			Euro score				EUTOS			1st line Treament		
	M	M_e		L	I	H	L	I	H	Un	L	H	Un	Im	Nil	Das
n	279	55	104	275	167	63	248	184	54	19	383	103	19	427	46	32
(%)	55.2		20.6	54.5	33	12.5	49.1	34.6	10.7	3.8	75.8	20.4	3.8	84.6	9.1	6.3

Summary/Conclusion: CML incidence in Andalusia is comparable to that described in the scientific literature and is in keeping with results from the European registry EUTOS from 2015. Epidemiological characteristics from our patients are homogeneous to those described in other registries in terms of sex, age of diagnosis and prognostication indices distribution. The creation of RALMC on population basis allows to obtain information regarding CML in real life, which is in turn needed for health planning and resource management in clinical praxis and support outside of clinical trials. However, methodological limitations in our registry must be taken into consideration: in Spain, CML patients are not obliged to declare their status, participation in RALMC is voluntary and inclusion is done under written consent.

PB1960

A STUDY TO IDENTIFY THE POPULATION VARIATION IN THE RESPONSE AND THE SIDE EFFECT PROFILE IN CHRONIC MYELOID LEUKEMIA-A NATIONAL EXPERIENCE FROM SRI LANKA

O. gamage[1,*], K. Perera[2], I. Wijesiriwardena[3]

[1]Haematology, Royal wolverhampton NHS Trust, Wolverhampton, United Kingdom, [2]Oncology, National Cancer Institute, [3]Haematology, University of Sri Jayawardhenapura, Colombo, Sri Lanka

Background: Imatinib, is the first tyrosine kinase inhibitor of the BCR-ABL protein. Imatinib was introduced for the treatment of with Chronic Myeloid Leukaemia (CML) in 2001.The discovery of the wonder drug, has changed the treatment paradigm of CML, now moving towards for the "treatment free remission". Appearance of kinase domain mutations and non-adherence are the main current challenges. Imatinib has proven its safety and efficacy in long term 10 year follow up data of IRIS study with overall survival of 83.3% without any cumulative or late toxic effects. The paucity of such studies analyzing the expanding Asian patient population, is a significant drawback in clinical practice, especially in explaining some side effects in them such as skin manifestations.
Aims: To look at the demographics in CML patients across the country in Sri Lanka and analysis of the response rates to Imatinib as the first line treatment in CML. To identify the variation of the side effect profile in the Sri Lankan population.
Methods: A total of 86 patients were treated with Imatinib as the first line TKI,who had completed minimum of 2 years of treatment were included. The data set was analyzed for basic demographics, Haematological and cytogenetic response. The side effect profile was analyzed, in relation to the time from starting treatment and the severity and graded the severity of cytopenias according to the WHO grading.
Results: Of the 86 patients, consist of 48 (56%) males and 38(44%) females, within the age of 15- 72 years at diagnosis, representing whole country. 38% of the patients were in high sokal risk category and 62% low or IM risk group. Analysis of the response to therapy according to the ENL response criteria 2016, revealed 89% hematological and 56% complete cytogenetic response achieved within optimal time frame. A detailed analysis of 36 patient's revealed 51% achieved a Major molecular response (MMR) by the completion of one year treatment. In terms of side effect profile, commonest during the first 6 months were of grade1 and 2, specifically gastrointestinal effects (86%), Skin hypopigmentation (69%), Muscular skeletal (63%), derangement of the liver enzymes(58%),fluid retention (32%) and other skin manifestations accounted in 20%. Of the haematological toxicities, neutropenia (57%) and thrombocytopenia (52%) were the commonest, and mostly grade 1 and 2 while, Grade 3 and 4 cytopenias were in 9 patients (10%). Most of the off target effects were settled after 6 months of the treatment. Most importantly, skin manifestations were the commonest which was persisted beyond 6 months of treatment. Interestingly, it was persisted in all the patients while on the treatment and was reversible on withdrawal. Skin hyperpigmentation was observed in 4 (7%).
Summary/Conclusion: Imatinib has induced optimal response in majority of patients. Therefore, Imatinib has shone it's efficacy in real life conditions, in our population. Reversible skin hypopigmentation is significantly higher than reported. There is higher events of transient liver derangement and cytopenias, could be explained by the smaller body built of the population.

PB1961

LATE MYOCARDIAL TOXICITY IN CHRONIC MYELOID LEUKEMIA (CML) PATIENTS ON LONG-TERM TYROSINE KINASE INHIBITOR (TKI) THERAPY

L. Genge[1,2,*], S. Narayanan[2], D. Hogge[2], M. Power[2], D. Sanford[2], D. Forrest[2], S. Nantel[2], M. Barnett[2], Y. Abou Mourad[2], A. Gerrie[2], K. Song[2], C. Toze[2], R. Broady[2], H. Sutherland[2], J. White[2], T. Nevill[2]

[1]Department of Internal Medicine, University of British Columbia, [2]Division of Hematology, Leukemia/BMT Program of BC, Vancouver, Canada

Background: Imatinib mesylate is a small-molecule TKI that dramatically changed the treatment landscape for patients with CML. Other TKIs have since been developed (e.g. Dasatinib) as second-line agents for intolerance or refractory disease. TKIs are generally well-tolerated with common side effects being nausea, diarrhea, fluid retention, myalgias and rash. TKIs were first implicated in cardiomyocyte toxicity following a report of ten CML patients who developed early congestive heart failure following treatment with Imatinib (Kerkela, 2006). Several *in vitro* and *in vivo* studies have since shown that Imatinib and Dasatinib can induce cardiotoxic effects via both on-target and off-target mechanisms, although the incidence in humans remains unclear (Force, 2011; Savi, 2018). There are no studies to date specifically examining myocardial toxicity in humans on long-term TKI treatment.
Aims: To describe a series of patients (pts) on prolonged TKI therapy for CML with documented myocardial toxicity without another identifiable etiology for the cardiac complication.
Methods: A retrospective chart and data base review was performed on pts with CML treated with TKIs by the Leukemia/BMT Program of BC over a 15-year period (2002-2017). Basic demographic data was collected along with date of commencement of TKI, disease status, TKI dose and response, adverse effects, duration of therapy at diagnosis of myocardial toxicity, investigation and management of cardiac complication and outcome. Specific attention was paid to the presence of traditional cardiac risk factors (RFs) and the presence of alternative etiologies for the myocardial toxicity.
Results: Five pts with chronic-phase CML were identified (Sokal score good-risk in 4 pts, intermediate-risk in 1 pt), 3 males and 2 females, with a median age of 52.6 years (yrs) (range 43.3-56.2) at diagnosis. Myocardial toxicity was identified at a median age of 61.9 yrs (range 56.5-71.1) after median total TKI therapy duration of 12.5 yrs (range 3.3-15.3). All pts had exposure to Imatinib for a median total of 12.5 yrs (range 0.5-15.3) and three had exposure to Dasatinib for median 0.5 yrs (range 0.3-2.8). Four pts had evidence of cardiomyopathy with reduced left ventricular ejection fraction, median 35% (range 20%-45%) by echocardiography, two with associated pericardial effusion. The fifth patient had a left atrial myxoma. RFs for atherosclerotic disease included obesity (2 pts), type II diabetes mellitus (1 pt) and remote (>25 yrs) smoking (1 pt). Two pts had remote exposure to cardiotoxic agents (Doxorubicin 26 yrs and Cyclophosphamide 15 yrs previously, respectively). Two pts had cardiac angiography and two pts had MIBI scan with no evidence of ischemic heart disease; all pts were assessed by a cardiologist with no other identifiable explanation for the cardiotoxicity aside from chemotherapy exposure. The atrial myxoma pt underwent surgical resection with no cessation of Imatinib while TKI therapy was held in all pts with cardiomyopathy. All pts commenced medical therapy, improved clinically and echocardiographically and were restarted on TKI therapy.
Summary/Conclusion: Despite strong mechanistic evidence of cardiomyocyte toxicity of TKIs, clinical reports in humans are rare. We present a series of pts with delayed cardiotoxicity in the form of cardiomyopathy with reduced systolic function and the first reported case of atrial myxoma presumed secondary to prolonged TKI therapy. Early screening of symptomatic individuals for cardiotoxicity from TKI therapy is strongly recommended.

PB1962

ADDITIONAL CYTOGENETIC ABNORMALITIES IN CHRONIC MYELOID LEUKEMIA; EXPERIENCE FROM PAKISTAN

N. Anwar*, S. Khurram, M. Nadeem, S. Shan, N. Fatima, M. Borhany, T. Shamsi

Hematology, National Institute of blood diseases and bone marrow transplantation, Karachi, Pakistan

Background: Chronic myeloid leukemia (CML) is characterized by formation of Philadelphia (Ph) chromosome as a result of reciprocal translocation between chromosome 22 and 9 *i.e.* t(9;22)(q34;q11.2). Additional cytogenetic abnormalities ACAs are reported internationally in 5-12% newly diagnosed CML.
Aims: The study was done to observe the frequency of cytogenetic abnormalities in CML in addition to Ph chromosome at the time of diagnosis, their baseline hematological characteristics and correlate their outcome on follow up.
Methods: This was a cross sectional study carried out at the department of Cytogenetics and Molecular Pathology of National Institute of Blood Diseases and Bone Marrow Transplant Karachi Pakistan from May 2010 to September 2016.All the patients diagnosed with CML during the study period on the basis of morphological and cytogenetic analysis were included and observed for ACAs. Baseline cytogenetic analysis was performed on overnight, 24-hrs unstimulated and 72-hrs stimulated bone marrow cultures using standard procedures. The GTG (G-bands via trypsin using giemsa) banding technique was applied, karyotypes were described according to the International System for Human Cytogenetic Nomenclature (ISCN) 2013, karyogram were made using Metasystem®. *BCR-ABL1* by real-time quantitative PCR was done by QIAGEN kits on Rotor-Gene Q 5plex HRM instrument with 72-tubes rotor, at baseline and at 18 months of treatment performed on peripheral blood and bone marrow. MMR was defined as 03 log reduction from the baseline.
Results: Out of total 222 cases of CML,18(8.1%) patients revealed ACAs; we found –Y, double Ph chromosome and trisomy 8, each in 01(6%) patient, complex karyotype in 5(28%) patients, del7q and hyperdiploidy each in 2(11%) patients. Two of the patients (11%) exhibited 3 way variant Ph translocations. We found lower median hemoglobin and platelet count and higher median eosinophil, basophil count and spleen size in patients with ACAs as compared to previously reported data. Our study also included the outcome of such patients followed at 6 and 18 months post treatment. Only 03 patients achieved major molecular response (MMR).

Summary/Conclusion: The main aim of the study was to highlight the importance of detecting ACAs in patients with CML at diagnosis. We also observed baseline characteristics and correlation of treatment response in such patients. As ACAs are reported to be associated with adverse outcomes and disease progression in literature, in this context our study would be valuable in adding additional information in local data

PB1963

DISCONTINUATION OF TYROSINE KINASE INHIBITORS IN PORTUGUESE CML PATIENTS: A SINGLE INSTITUTE EXPERIENCE

N. Cerveira[1,*], B. Loureiro[2], S. Bizarro[1], C. Correia[1], L. Torres[1], S. Lisboa[1], J. Vieira[1], D. Pereira[2], C. Moreira[2], S. Chacim[2], N. Domingues[2], A. Espírito-Santo[2], I. Oliveira[2], I. Moreira[2], L. Viterbo[2], Â. Martins[2], M.R Teixeira[1,3], J.M Mariz[2]

[1]Department of Genetics, [2]Department of Onco-Haematology, Portuguese Oncology Institute, [3]Institute of Biomedical Sciences (ICBAS), University of Porto, Porto, Portugal

Background: In the last few years, several clinical discontinuation trials have demonstrated that 40-60% of chronic phase CML patients (CP-CML) who have achieved a stable deep molecular response (DMR), defined as a sustained molecular response of at least 4.5 ($MR^{4.5}$), can stop therapy without relapsing. In addition to DMR, other variables that have been associated with a successful treatment-free remission (TFR) include low Sokal risk group at diagnosis, chronic-phase disease, optimal response to TKI therapy, longer duration of TKI therapy (>8 years), and longer duration of DMR (>2 years). In all published trials, the majority of patients who experienced relapse did so within 6 months of TKI cessation and, with the exception of one case that progressed to blast crisis, relapsed patients remained responsive to retreatment and regained at least a major molecular response (MMR). However, most information on treatment cessation was obtained from clinical trials with strict recruiting criteria.
Aims: In this study, we aimed to assess persistence of TFR in 25 CML patients treated at our institution that discontinued therapy due to several causes including DMR and TKI intolerance, and to identify factors that could be associated with TFR.
Methods: The medical records of all CP-CML patients who were treated with TKIs in our institution between 1997 and 2015 were reviewed and clinical and laboratory data was collected. The eligibility criteria were CP-CML, treated with any of the first-line approved TKIs (Imatinib, Nilotinib, and Dasatinib), that discontinued TKI therapy due to any reason. Only patients with typical transcripts [that is, b3a2 (e14a2) and/or b2a2 (e13a2)], determined by RT-PCR at the time of diagnosis were included.
Results: We evaluated the outcome of 25 patients with CML that discontinued TKI therapy in our institute due to any reason. Of them, 76% discontinued therapy in sustained deep molecular response (SDMR) and 24% were in unsustained DMR (UDMR). Discontinuation of therapy due to adverse effects was observed in 5% and 50% of the patients in the SDMR and UDMR groups, respectively. After TKI discontinuation patients were followed for a median of 20 months. At the time of this analysis, 56% patients had a molecular relapse after a median of 4 months. SDMR and longer treatment duration were associated with lower probability of molecular relapse: 25% in SDMR patients with TKI treatment >96 months patients and 85% in UDMR patients with TKI treatment ≤96 months. All relapsed patients promptly resumed TKI therapy and regained at least a major molecular response (MMR).
Summary/Conclusion: Our results suggest that TKI discontinuation is safe outside clinical trials and particularly effective in CML patients who are in SDMR with longer duration of TKI treatment.

PB1964

THE EVALUATION OF THE TOTAL ANTIOXIDANT CAPACITY IN RELATION TO THE TREATMENT WITH TYROSIN-KINASE INHIBITORS IN CHRONIC MYELOID LEUKEMIA

M.-A. Gaman[1,*], *e.g.* Pascu[2], A.M. Gaman[2,3]

[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Bucharest, [2]Pathophysiology, University of Medicine and Pharmacy of Craiova, [3]Hematology, Filantropia City Hospital of Craiova, Craiova, Romania

Background: Chronic myeloid leukemia (CML) is a chronic myeloproliferative neoplasm arising from the reciprocal translocation t(9;22) which is the source for the bcr-abl P210 protein that determines the development and perpetuation of the leukemic granulocytic clone. Increased levels of oxidative stress, defined as an imbalance of the redox status of the cell induced by overproduction of reactive oxygen species or decreased antioxidant defense, lead to chromosomal abnormalities, promote genomic instability and blastic transformation, and are possibly responsible for the development of resistance to tyrosin-kinase inhibitors (TKI). The involvement of oxidative stress has been studied in aging and other physiological processes, and also in a couple of hematological disorders: essential thrombocythemia, chronic lymphocytic leukemia or primary immune thrombocytopenia[1-8].
Aims: To evaluate the levels of oxidative stress and the total antioxidant capacity in order to establish a possible link between oxidative stress, TKI therapy and molecular response in patients with CML.
Methods: We evaluated 26 patients with chronic phase CML, diagnosed according to the ELN/WHO criteria, hospitalised in the Clinic of Hematology, Filantropia City Hospital Craiova, Romania, compared to healthy controls. Informed consent was obtained from all recruited participants. The patients were treated with first or second generation TKI. Oxidative stress was evaluated at diagnosis and when switching from first to second generation of TKI was decided, and correlated with the molecular response (MR). We evaluated the total antioxidant capacity (TAC) using a multidetection microplate reader FLUOstar Omega and a Sigma-Aldrich antioxidant assay kit. The BCR-ABL transcript was detected by RT-PCR. The statistical analysis was performed using the student T-test and a p-value ≤0.05 was considered significant.
Results: The study group included 14 males and 12 females (age range 23-84 years). The patients were treated with first generation TKI as first line therapy. Due to intolerance or failure to first generation TKI, 7 patients required second generation TKI as second line therapy. All patients with CML had low levels of TAC compared to healthy controls ($p \leq 0.05$), with a lower level in patients with intolerance or failure to first generation TKI and switched to second generation TKI ($p \leq 0.05$). We found a significant correlation between the low level of TAC, types of TKI, BCR-ABL transcript and MR.
Summary/Conclusion: In our study group, low levels of TAC were found in CML patients compared to healthy controls. Patients that were switched from first to second generation of TKI had significantly lower TAC levels. Our study is ongoing, but we suppose that oxidative stress plays a role in genomic instability and self-mutagenesis, causing TKI resistance via a bcr-abl independent mechanism.

STANDARDIZATION AND VALIDATION OF A NOVEL AUTOMATED DIGITAL ANALYSIS OF RED BLOOD CELLS MORPHOLOGY

S. Payán Pernía*, R. Awol, M. Serra Ferrer, J. Sánchez García, V. Criado Casas, X. Sales García, Á.F. Remacha Sevilla

Hematology, Hospital De La Santa Creu I Sant Pau, Barcelona, Spain

Background: Assessment of erythrocyte morphology is essential in the study of anaemia. However, microscopic evaluation of peripheral blood smears is a time-consuming procedure. Automated digital cell morphology analysers could simplify and standardize this evaluation. These platforms have recently incorporated red blood cells (RBC) morphology evaluation.
Aims: Standardization of the morphological analysis of RBC performed by the CellaVision Advanced RBC Software Application.
Methods: Standardization: The values of macrocytosis and microcytosis proposed by Cellavision were recalibrated according to those obtained with XN analysers (Sysmex Corporation, Chuo-ku, Kobe, Japan) in several pathological samples. Subsequently, the reference interval for each of the different morphological anomalies of RBC was calculated in 67 subjects with normal mean corpuscular volume, RBC and reticulocyte count, and iron metabolism. Three levels of intensity were defined for each morphological anomaly according to the 2015 ICSH recommendations: 1 (mild), 2 (moderate) and 3 (intense). The intra-day and inter-day reproducibilities were assessed. For the intra-day study, 5 smears of the same blood sample were analysed along the same day. For the inter-day study, three different blood smears were obtained for each sample and analysed at 0, 24, and 48 hours. Validation: 100 patients with anaemia were selected. The results of the automated system were compared with those obtained through microscopic evaluation of direct blood smears (without anticoagulant). For each patient, morphology was evaluated by the automated digital system, by an experienced technician, and by a hematologist (the reference). According to results, morphology was divided into three categories: normal or without clinical relevance, compatible with the type of anaemia (e.g. hypochromia in iron deficiency anemia), and relevant for the diagnosis (e.g., schistocytes). STATISTICS: In the reference population, intervals were calculated and morphological findings were compared using the Student's t-test. In the validation study, concordance (agreement) between results was analysed by the *kappa index statistic*. METHODOLOGY: Blood was collected in EDTA-anticoagulated tubes. The automated morphological analysis was performed with the CellaVision Advanced RBC Application on the DM96 analyser (CellaVision AB, Lund, Sweden). Blood smears for the automated analysis were performed and stained using the SP-10 (*Sysmex Corporation, Chuo-ku, Kobe*, Japan), an automated slide maker and stainer.
Results: Statistically significant differences were found for macrocytosis and dacryocytes with regard to sex. In the analysis of the intra-day reproducibility, no differences were observed. A decrease in stomatocytes and an increase in equinocytes were detected in the inter-day analysis. VALIDATION: Results obtained by the technician using the direct blood smear coincided with those retrieved by the haematologist in 92.5% of cases (κ=0.918). The automated analysis agreed with the hematologist's results in 93.7% of the cases (κ=0.879).
Summary/Conclusion: The automated evaluation of RBC morphology using the CellaVision Advanced RBC Software Application offered reproducible intra-day but not inter-day results. Its standardization allowed the evaluation of the RBC morphology in a faster way and with decreasing variability. There was an excellent concordance between the morphological assessment by CellaVision and by optical microscopy in the setting of anaemia.

PB1966

THE PEAK REGISTRY, A GLOBAL LONGITUDINAL OBSERVATIONAL STUDY OF PATIENTS WITH PYRUVATE KINASE DEFICIENCY

P. Bianchi[1], B. Glader[2], R.F. Grace[3], H. Kanno[4], D.M. Layton[5], C. Rose[6], E.J. van Beers[7], J.-L. Vives Corrons[8], L. Hua[9], B. Jones[9,*]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy, [2]Stanford University School of Medicine, Palo Alto, [3]Dana-Farber Boston Children's Cancer and Blood Disorders Center, Boston, United States, [4]Faculty of Medicine, Tokyo Women's Medical University, Tokyo, Japan, [5]Hammersmith Hospital, Imperial College Healthcare NHS Trust, London, United Kingdom, [6]Hôpital Saint Vincent de Paul, Lille, France, [7]University Medical Centre Utrecht, Utrecht, Netherlands, [8]Josep Carreras ICO-Germans and University of Barcelona, Barcelona, Spain, [9]Agios Pharmaceuticals, Inc., Cambridge, United States

Background: Pyruvate kinase (PK) deficiency is a rare hereditary glycolytic enzymopathy caused by mutations in the *PKLR* gene, which lead to reduced red blood cell PK (PK-R) enzyme activity, resulting in defective red blood cell glycolysis and hemolytic anemia. It is the most common cause of glycolytic hemolytic anemia. Over 300 causative *PKLR* mutations have been identified to date. Patients with PK deficiency may experience symptoms of hemolytic anemia, most commonly fatigue (sometimes extreme), jaundice, dyspnea and weakness. Current treatment is limited to supportive care options. Affected neonates may need phototherapy or exchange transfusions for severe hyperbilirubinemia, while treatment strategies for adults can include red blood cell transfusions, splenectomy/cholecystectomy, and iron chelation, each of which is associated with some risk to the patient. No disease-specific therapy currently exists. The observational PK deficiency Natural History Study (NHS) conducted by Boston Children's Hospital (ClinicalTrials.gov NCT02053480; N=258) initiated the longitudinal analysis (2-year follow-up) and reporting on PK deficiency-related signs, symptoms and treatment outcomes to better understand the natural history and clinical burden of the disease. The Peak Registry, a global, longitudinal, non-interventional study of PK deficiency, aims to build upon the NHS with additional patients and longer follow-up.
Aims: To report the design of the Peak Registry.
Methods: The Peak Registry is a global, longitudinal, observational registry for adult and pediatric patients with PK deficiency. The 9-year study will enroll approximately 500 patients over 7 years at an estimated 60 study centers in up to 20 countries. All enrolled patients will be followed prospectively for at least 2 years, and up to 9 years. Patients of all ages with a diagnosis of PK deficiency confirmed by genetic testing are eligible to enroll. Each patient or their parent/guardian must be willing and able to give written informed consent and/or assent. Patients who are actively enrolled in any Agios-sponsored clinical trial involving treatment with a PK activator will be excluded. Demographic, clinical, and treatment data, and other data relevant to the management of patients with PK deficiency, will be collected from participating registry physicians via electronic case report forms. The primary objective of the registry is to develop an understanding of the longitudinal clinical implications of PK deficiency, including natural history, treatment and outcomes, variability in clinical care, and disease burden. Secondary objectives include: to understand the prevalence, incidence, and severity of complications associated with PK deficiency; examine phenotype-genotype correlation; evaluate pregnancy outcomes; and provide longitudinal data to assist physicians with the clinical management of individual patients. Site and patient recruitment are ongoing. Study conduct, data analyses and reporting is governed by a steering committee comprised of experts involved in the research, diagnosis, and/or care of patients with PK deficiency in cooperation with the sponsor (Agios Pharmaceuticals, Inc.).
Results: Not yet available.
Summary/Conclusion: This non-interventional study aims to extend the work of the NHS with additional patients from an expanded geographic distribution and longer follow-up, to further improve the understanding of the complex clinical burden of PK deficiency, its natural history, and outcomes of current treatment practice patterns.

PB1967

A FEW WORDS ABOUT APLASTIC ANEMIA IN ARMENIA

S. Daghbashyan*, N. Melkikyan, L. Sahakyan, A. Tovmasyan

Armenian Haematology center aft.prof.R.Yeolyan, Yerevan, Armenia

Background: Aplastic anemia is a kind of disease which occurs in the result of bone marrow stem cell damage which causes a deep inhibition of the hematopoiesis' three germs in the bone marrow. Aplastic anemia is a quite rare disease, but at the same time it is one of the most severe disorders of hemopoiesis with a mortality rate exceeding 80%. In most cases it occurs among young people.
Aims: We aimed to quantify the incidence, prevalence and survival rate aplastic anemia patients in Armenia and their variation with gender, age, year of diagnosis.
Methods: In this work we included aplastic anemia patients diagnosed within 2005 to 2017. The initial data for this survey have been derived from ambulance/dispensary cards, hospitalization journals, and clinical data from the Registry of Blood Diseases at the R.Yeolyan Hematology Center, Yerevan, Armenia. The data has been supplemented by the data from the Registry of Oncological Diseases of the V. Fanarjyan NCO, as well as from death certificates. The demographic data has been obtained from the National Statistics Board of Republic of Armenia. The obtained data has been statistically analyzed using EPI INFO-2002 program.

Results: A total of 69 cases of aplastic anemia were identified, 41 (59.4%) of whom were male. The overall incidence of aplastic anemia was 1.8 per million inhabitants per year (95%CI 0.9–2.9) and the incidence increased with age. The higher incidence rates were noted in 2008 and 2014 (accordingly 0.25 and 0.29). The sex-specific incidence rates were 2.2 for males and 1.7 for females (ratio 1.29). Patients can be affected at any age, although there is a biphasic age distribution with peaks from 10 to 25 (2.9 per million per year) years and >60 years (1.7 per million per year). Most of the cases were classified as severe or very severe aplastic anemia. Currently 46.4% of studied patients are alive. Survival rates at 5 and 10 years after the diagnosis were 50% and 37%, respectively. Age and disease severity at the time of diagnosis were associated with a lower survival rate.
Summary/Conclusion: This is the first general population study to describe the incidence of AA in Armenia during 2005-2017. It forms the basis for quality assessment of aplastic anemia treatment in Armenia and offers a unique opportunity for population-based research. The incidence of aplastic anemia in Armenia is low but the case fatality rate is high. Advanced age and severe disease at the time of diagnosis were associated with decreased survival.

PB1968

UNVEILING THE UTILITY OF AUTOMATED RBC AND PLATELET PARAMETERS IN THE EVALUATION OF VITAMIN B12 DEFIFIENCY ANEMIA

R. Rajashekar*

Hematopathology, JSS Medical College, MYSORE, India

Background: Vitamin B12 deficiency induced megaloblastic anemia is diagnosed by complete blood count (CBC) parameters including RBC indices such as mean corpuscular volume (MCV), red cell distribution width-coefficient of variation and standard deviation (RDW-CV, RDW-SD).Platelet indices such as mean platelet volume (MPV), platelet distribution width (PDW) and platelet large cell ratio (P-LCR) have been evaluated in thrombocytopenias of various etiologies.The present study aimed at exploring the reliability, diagnostic accuracy and utility of automated RBC and platelet parameters in evaluating vitamin B12 deficiency induced anemia and thrombocytopenia.
Aims: 1.To evaluate MCV, RDW-CV and RDW-SD for their ability to detect vitamin B12 deficiency and related anemia.2.To evaluate the diagnostic accuracy of RDW-SD *versus* RDW-CV.3.To evaluate the discriminative function of platelet indices in thrombocytopenia of megaloblastic etiology in comparison with hypoproductive and hyperdestructive causes of thrombocytopenia and to correlate platelet indices with bone marrow megakaryocyte cellularity.
Methods: This retrospective analytical study included 100 cases with serum levels of vitamin B12<200 pg/ml. The hemoglobin, MCV, RDW-CV and RDW-SD were estimated by Sysmex XN-1000. Pearsons correlation was used for calculating the correlation of hematological parameters. Among 100 cases, 32 had thrombocytopenia and underwent bone marrow biopsy. Platelet indices in these 32 cases of thrombocytopenias of megaloblastic etiology were compared with platelet indices of 31 cases of marrow proven hypoproductive thrombocytopnias (aplastic anemia, hypoplastic anemia, acute leukemia) and 32 cases of hyperdestructive thrombocytopnias (Immune thrombocytopenia).Descriptive analysis was used and comparison of means in all the groups was done with one way ANOVA using Scheffe's test. Categorical data was analyzed using Chi-square test.Platelet indices and bone marrow megakaryocytes were analyzed and correlated in each group. A p-value of less than 0.05 was considered statistically significant.
Results: Among 100 cases of vitamin B12 deficiency, elevated RDW-SD, RDW-CV and MCV were seen in 90%, 72% and 64% cases respectively. RDW–SD showed a strong negative correlation with serum vitamin B12 levels (p-value= 0.029) (p<0.05).RDW-CV showed a weak negative correlation with serum Vitamin B12 levels with an insignificant p-value of 0.58 (p>0.05). The sensitivity of RDW-SD, RDW-CV and MCV were 95%, 81% and 69.1% respectively for detection of anemia. Mean values of platelet indices were higher (p<0.05) in hyperdestructive group [PDW(16.6fL), MPV(12.1fL), P-LCR(42.3%)] compared to the hypoproductive group [PDW(11.8fL), MPV(10.9fL), P-LCR(31.5%)].Mean values of PDW (14.7fL) and MPV (11.6fL) in megaloblastic group showed a higher value (p-value<0.05) than hypoproductive group but no significant difference was seen compared to hyperdestructive group (p-value>0.05).The mean P-LCR (37.4%) in megaloblastic group was intermediate from the other two groups (p-value<0.05).
Summary/Conclusion: RDW-SD is the most sensitive discriminant function even when MCV is normal despite vitamin B12 deficiency, since so far all the attention is being given to MCV as the earliest hematologic indicator of vitamin B12 deficiency. Platelet indices are of significant discriminative value in differentiating the various causes of thrombocytopenias. Both hypoproduction and ineffective thrombo-poiesis are the underlying pathomechanisms in megaloblastic thrombocytopenia as evidenced by the marrow findings and platelet indices.

PB1969

ROLE OF IRON METABOLISM, INTERLEUKIN-6, INTERLEUKIN-10, TUMOR NECROSIS FACTOR ALPHA IN PROGRESSION OF ANEMIA IN PATIENTS WITH SOLID TUMORS

V. Sakhin[1,*], M. Pugachev[2], E. Madzhanova[3], A. Sotnikov[4], A. Gordienko[4], S. Kazakov[5], E. Kryukov[6], O. Rukavitsin[7]

[1]Cardiology department, 1586 military hospital of the Ministry of Defense of Russia, Moscow region, Podolsk, [2]Therapeutic department, 1602 military hospital of the Ministry of Defense of Russia, Rostov-na-Donu, [3]Immunochemical laboratory, 1586 military hospital of the Ministry of Defense of Russia, Moscow region, Podolsk, [4]Department of Hospital Therapy, Russian Military Medical Academy of the Ministry of Defense of Russia, St. Petersburg, [5]Center for Clinical Laboratory Diagnostics, [6]Head of the hospital, [7]Hematology Center, Main Military Hospital n.a. N. Burdenko, Moscow, Russian Federation

Background: A significant number of cancer patients need correction of anemia. Anaemia has a negative impact on quality of life as well as survival. Iron metabolism disorder and cytokines plays important roles in the pathogenesis of this anaemia. The mechanism of their action needs specification.
Aims: To study the aspects of iron transfer and influence of interleukin-6 (IL-6), interleukin-10 (IL-10) and tumor necrosis factor-alpha (TNF-) on progression of anemia in patients with solid tumors
Methods: Sixty-three patients (forty one patients with anaemia/ twenty two patients without anaemia) with Stage II-IV cancer were examined. RBC count, WBC count were performed, levels of HB, HCT, MCV, MCH, MCHC were determined using Sysmex XS-500i analyser (Japan). Serum iron concentration, total iron binding capacity (TIBC), ferritin level, C-reactive protein (CRP) level, transferrin saturation index (TSI) were determined using Olympus Au 480 analyser, (Beckman Coulter, the USA). Concentration of transferrin was determined by Siemens Admia 1200 analyser (Diamond Diagnostics, the USA). Concentrations of IL-6, IL-10 and TNF-α were determined using Stat Fax 2100 analyser (Awareness Technology Inc., the USA). Mann-Whitney U Test was applied to check for statistically significant differences in study samples. In order to evaluate the relation between the variables Spearman correlation coefficient (r) was calculated.
Results: Patients with anaemia show lower concentrations in comparison with patients without anaemia: serum iron (5.5 [IQR, 2.9-7.7] *versus* 10.9 [IQR, 7.9-14.7]; p<0.05), TSI (11.4 [IQR, 5.1-14.3] *versus* 17.7 [IQR, 12.5-23.7]; p<0.05), TIBC (50.2 [IQR, 39-60] *versus* 64.2 [55.5-73.1]; p<0.05), lower levels of HCT (30.1 [IQR, 26.9-33.8] *versus* 40 [36.5-44.5]; p<0.05), MCH (26.9 [IQR, 24.8-29] *versus* 29.4 [27.2-31.6]; p<0.05), MCHC (318.9 [IQR, 302.5-331] *versus* 338.8 [327.5-350]; p<0.05), and higher concentrations of CRP (103.7 [IQR, 32.1-155] *versus* 34.5 [IQR, 9.3-65.7]; p<0.05), IL-6 (41.5 [IQR, 3.8-31.1] *versus* 7.1 [IQR, 0.00-9.4]; p<0.05), IL-10 (18.3 [IQR, 4.5-14.4] *versus* 0.9 [IQR, 0.3-5.5]; p<0.05) and TNF-α (58.6 [IQR, 36.1-81.1] *versus* 8.25 [IQR, 1.3-13.6]; p<0.05). Concentrations of ferritin, transferrin and MCV level in both groups were the same (p>0.05). As for iron, there was a correlation with HB level (r=0.37) and no correlation with RBC level was found (r<0,3). A correlation with levels of RBC (r=-0.55), HB (r=-0.52), HCT (r=-0.51) and WBC (r=0.45) was found for IL-6. A correlation with level of HB (r=-0.64) was found for IL-10. A correlation with levels of RBC (r=-0.74), HB (r=-0.69), HCT (r=-0.63), WBC (r=0.39) was found for TNF-α. A correlation with WBC (r=0.77), HB (r=-0.74), HCT (r=-0.71), RBC (r=-0.6), MCH (r=-0.32), and MCHC (r=-0.54) levels was found for IL-10.
Summary/Conclusion: Data obtained prove the fact that anaemia in cancer patients is associated with progression of functional deficit of iron. A correlation between IL-6, IL-10, TNF-α and hemogram items indicates their significant influence on anaemia progression and evidences its complicated nature, which is not limited by iron deficit only. Mechanism and intensity of cytokines influence on progression of anaemia in cancer patients need further clarification

PB1970

HLA-DR ALLELES ASSOCIATED WITH THE DEVELOPMENT OF AUTOIMMUNE HEMOLYTIC ANEMIA

S. Smirnova*, E. Khamaganova, Y. Sidorova, A. Abakumova, I. Urybin, A. Sudarikov

National research center for hematology, Moscow, Russian Federation

Background: The association of HLA I and II class antigens with the development of autoimmune diseases (AD) had been reported for the Ankylosing spondylitis, rheumatoid arthritis, systemic lupus erythematosus, type 1 diabetes mellitus, acquired form of idiopathic thrombotic thrombocytopenic purpura, etc. HLA complex responsible for antigen presentation to T-lymphocytes play an important role in immune response, however the mechanisms underlying the association of HLA antigens with the development of AD are not fully understood. According to the literature, there is a negative correlation between the presence of HLA-DQ6 and the positive direct Coombs test in the patients with idiopathic immune hemolytic anemia (IHA) and hemolysis secondary to other neoplastic or viral diseases. Possible association of HLA antigens with the development of autoimmune hemolytic anemia (AIHA) has not been studied yet.
Aims: Identify the association of HLA-DR antigens with the development of AIHA.
Methods: The study included 24 patients with AIHA (diagnosed according to WHO 2016 classification) and 1507 healthy donors. Male to female ratio was 1:2.4. The median age was 37. Haplotypes of the DRB1 locus were assessed by SSP-HLA-typing for patients with AIHA (48 haplotypes) and healthy donors (3014 haplotypes).
Results: Comparison of control and study groups revealed DRB1 alleles with altered frequency of occurrence. Frequencies of DRB1*03 alleles (7 out of 48 examined haplotypes; 14% *vs* 8% in the control group), DRB1*09 (3 of the 48 haplotypes studied; 6% *vs* 0.86% in the control group), DRB1*16 (4 of 48 examined haplotypes; 8% *vs* 3% in the control group) were increased in AIHA group. While DRB1*11 (2 of the 48 haplotypes studied; 4% *vs* 13% in the control group) and DRB1*15 (2 of the 48 haplotypes studied; 4% *vs* 13% in the control group) occur more often in the control cohort.
Summary/Conclusion: We have observed an increased incidence of the DRB1*03 allele among patients with AIHA. It should be noted that an increased incidence of this allele among patients with type 1 diabetes, celiac disease, diffuse toxic goiter, myasthenia gravis had been reported previously for European population. Incidence of DRB1*09 allele, which is frequent for Asian population and is very rare for European population, was also increase in Russian patients with AIHA. No association of DRB1*11 or DRB1*15 alleles with any AD had been reported so far. The altered frequencies of these alleles could be associated with the severity of the disease, resistance to therapy, or with other factors. Further studies with extended patients cohorts and long-term dynamic monitoring of patients are required for the definite interpretation of these observations.

PB1971

ROLE OF HEPCIDIN AND SOLUBLE TRANSFERRIN RECEPTOR IN PATHOGENESIS OF ANAEMIA IN PATIENTS WITH SOLID MALIGNANT TUMORS

V. Sakhin[1,*], M. Pugachev[2], E. Madzhanova[3], A. Sotnikov[4], A. Gordienko[4], S. Kazakov[5], E. Kryukov[6], O. Rukavitsin[7]

[1]Cardiology department, 1586 military hospital of the Ministry of Defense of Russia, Moscow region, Podolsk, [2]Therapeutic department, 1602 military hospital of the Ministry of Defense of Russia, Rostov-na-Donu, [3]Immunochemical laboratory, 1586 military hospital of the Ministry of Defense of Russia, Moscow region, Podolsk, [4]Department of Hospital Therapy, Russian Military Medical Academy of the Ministry of Defense of Russia, St. Petersburg, [5]Center for Clinical Laboratory Diagnostics, [6]Head of the hospital, [7]Hematology Center, Main Military Hospital n.a. N. Burdenko, Moscow, Russian Federation

Background: A significant number of cancer patients need correction of anemia. Iron metabolism disorder and play important roles in the pathogenesis of this anaemia. Hepcidin is the main circulating in the blood regulator of iron absorption and its distribution in tissues. Soluble transferrin receptor binds transferrin and the resulting complex transports iron into the cell. The importance of hepcidin and soluble transferrin receptor in pathogenesis of anemia in patients with solid malignant tumors requires clarification.
Aims: To study the aspects of hepcidin and soluble transferrin receptor (sTfR) release in patients with solid malignant tumor and anaemia, and its relation with values of iron metabolism, interleukin-6 (IL-6), interleukin-10 (IL-10) and tumour necrosis factor-alpha (TNF-α).
Methods: Sixty-three patients (41 patients with anaemia/ 22 patients without anaemia) with Stage II-IV cancer were examined. RBC count was performed, levels of HB, HCT, MCV, MCH, MCHC were determined using Sysmex XS-500i analyser (Japan). Serum iron concentration, total iron binding capacity (TIBC), ferritin level, C-reactive protein (CRP) level, transferrin saturation index (TSI) were determined using Olympus Au 480 analyser, (Beckman Coulter, the USA). Concentration of transferrin was determined by Siemens Admia 1200 analyser (Diamond Diagnostics, the USA). Concentrations of IL-6, IL-10 and TNF-α were determined using Stat Fax 2100 analyser (Awareness Technology Inc., the USA). Concentration of sTfR was determined using ACCESS analyser (BeckmanCoulter, the USA). Hepcidin concentration was determined using Charity photometer (Promnauchpribor, Russia). Mann-Whitney U Test was applied to check for statistically significant differences in study samples. In order to evaluate the relation between the variables Spearman correlation coefficient (r) was calculated.
Results: Patients with anaemia show higher concentrations in comparison with patients without anaemia: hepcidin (47.8 [IQR, 50-57.8] *versus* 33.6 [IQR, 21.1-50]; $p<0.05$), sTfR (30.7 [IQR, 16.4-63.3] *versus* 17.3 [IQR, 14.9-19.2]; $p<0.05$). A correlation with levels of RBC (r=-0.41), HCT (r=-0.35), CRP (r=0.49), TIBC (r=-0.51), ferritin (r=0.61), transferrin (r=-0.55), IL-6 (r=0.52), TNF-α (r=-0.41) was found for hepcidin. A correlation with levels of HB (r=-0.57), HCT (r=-0.5), transferrin (r=0.41), IL-10 (r=0.57) was found for sTfR.
Summary/Conclusion: higher concentration of hepcidin and sTfR in patients with solid malignant tumor and anaemia in comparison with patients without anaemia, as long as its correlation with values of RBC, HB and HCT evidence the participation of hepcidin and sTfR in progression of anaemia in these patients. Correlations between hepcidin, sTfR and values of iron metabolism indicate that these proteins effect on progression of anaemia through its influence on iron metabolism. The correlations between hepcidin, IL-6 and IL-10, as well as correlations between sTfR and IL-10 values evidence a regulating role of cytokines in synthesis of reviewed transferrin receptors.

PB1972

PREVALENCE OF PERNICIOUS ANEMIA IN PATIENTS WITH LOW B12 LEVEL IN AN INDIAN TERTIARY CARE HOSPITAL

A. Dubey*, B. Palate

Haematology, Haemato-oncology and Bone Marrow Transplant, P D hinduja Hospital, Mahim, Mumbai, Mumbai, India

Background: Pernicious anemia is a chronic illness where body fails to produe normal red blood corpuscles because of Vitamin B12 deficiency caused as a result of impaired absorption due to lack of intrinsic factor, which may be due to the presence of intrinsic factor antibody or gastric parietal cell antibody leading to gastric atrophy. It is the most common cause of Vitamin B12 deficiency in the west, however in a study conducted by Desai *et al.* the incidence of pernicious anemia was found to be very low in Indian subjects. Moreover, majority of these vitamin B12 deficient patients do not get investigated for pernicious anemia as the deficiency is attributed to the vegeterian diet of the patients. This retrospective study shows that the incidence of pernicious anemia in the Indian population may be higher than reported till now.
Aims: To evaluate the prevalence of pernicious anemia in patients with documented low serum vitamin B12 levels in Mumbai.
Methods: A total of 133 patients with clinical suspicion of Vitamin B12 deficiency who were not recently transfused within the last one week or were not on vitamin B12 supplements were tested for serum vitamin b12 levels. Out of these, 38 patienst found to have severely low levels of levels of vitamin b12 of less than 150pg/ml were then tested for gastric parietal cell antibody and intrinsic factor antibody.
Results: A total of 8 patients from the 132 patients tested were found to have Pernicious Anemia. Out of these, 2 were positive for only intrinsic factor antibody, 5 were positive for only gastric parietal cell antibody while one patient was positive for both the antibodies. The latter patient was also found to be Anti TPO antibody positive and referred for further endocrinological evaluation. Of note is the factt hat 2 patients had equivocal intrinsic factor antibody levels while 3 patients had equivocal gastric parietal cell antibody levels within the values falling on the upper limit of the reference range and for all practical purposes, these patients were treated as having pernicious anemia.
Summary/Conclusion: The prevalence of pernicious anemia is reported to be lower in Chinese, Blacks and the Indian population. Till date, studies reported in India have further emphasized this fact. However, this retrospective study shows that the incidence of pernicious anmeia is higher than reported and has important implications in the treatment of the patients.

PB1973

MOLECULAR CHARACTERIZATION OF RED CELL PYRUVATE KINASE DEFICIENCY IN INDIA: A STUDY OF 22 CASES

P. Kedar*, R. Dongerdiye, R. Devendra, A. Chiddarrwar, V. Gupta

V. Thorat, P. Warang, M. Madkaikar

Haematogenetics, National Institute of Immunohaematology (ICMR), Mumbai, India

Background:-Pyruvate kinase (PK) deficiency is one of the most common causes of hereditary hemolytic anemia around the world with clinical manifestations varying from mild to severe hemolysis. Here we investigate PK-deficient cases referred to our laboratory for biological analysis of the unknown cause of hemolytic anemia.
Aims: To diagnose Pyruvate kinase deficiency (PKD) in hereditary non spherocytic hemolytic anemia cases in India and Genotype-phenotype correlations in PKD
Methods: Test for aaemoglobinopathies, RBC membrane protein defects and red cell enzyme activities were measured by standard methods; Molecular characterization of the PK gene mutations included restriction enzyme analysis, mutation scanning by DNA sequencing. In silico prediction using bioinformatics tools (SIFT, Polyphen2) was done and the molecular modeling were performed using PYMOL software.
Results: Total 21 families were identified in which 17 homozygous PKD cases identified and eighteen different PKLR mutations were found among which six are described for the first time (V294M, I282S, M373V, A423E, W525X and R559X) and 11 known mutations which includes (E315K, D331G, G332S, G358R, N393S,E407K, R486W, R479H, R498C, V506I, R510Q and IVS9 ds A-G +3) are associated with severe clinical presentation. All missense mutations were located in crucial domains of the molecule (catalytic site, cleft between the A and C domains, A/A' interface and have severely damaging effect leading to need of regular blood transfusion. The most frequent mutations in the Indian population appear to be V294M, followed by R479H, R510Q and D331G. Genotype-phenotype correlations for the novel mutations were investigated by three-dimensional structure analysis.
Summary/Conclusion: In India, the genetic heterogeneity of PKLR is still high but differs from that observed in the previous study carried out in 2009 and 2013. DNA sequencing was helping for genetic counseling and prenatal diagnosis.

PB1974

HB KIRKLARELI (AH58L): SECOND DESCRIPTION IN A BRAZILIAN PATIENT WITH DYSPNEA AND O2 SATURATION FALL

M.D.F. Sonati[1,*], G. Pedroso[1], P. Nascimento[1], D. Albuquerque[2], M. Grigoleto[1], M. Santos[1], F. Costa[2], S. Jorge[1]

[1]Clinical Pathology, [2]Hematology and Hemotherapy Center, State University of Campinas-UNICAMP, Campinas, Brazil

Background: Hemoglobin (Hb) Kirklareli [$\alpha_1$58(E7)His®Leu;HBA1: c.176A®T] was first described by Bissé *et al*. in 2016 as a new α-globin variant associated with iron deficiency and increased CO binding. It was found in a Turkish female patient with mild anemia and in her father, who was not anemic but was a smoker with high levels of HbCO. Studies with recombinant human Hb Kirklareli showed that the αH58L subunits autoxidize and lose hemin more rapidly than native α subunits causing rapid denaturation of the oxygenated variant under physiological conditions. On the other hand, the mutant α subunits showed a much higher affinity for CO than O2, which prevents denaturation and explains the phenotypic differences between the patient and her father.
Aims: We found the Hb Kirklareli mutation in the α_2-globin gene (HBA2:c.176A®T) of a Brazilian patient admitted to the university hospital with severe dyspnea and O2 saturation fall and in his father, who presented with normocytic and normochromic moderate anemia. Our patient is an 11-year-old White male of Portuguese descent with history of respiratory problems since he was 6-y-o. Cardiac and pulmonary functions, inhalation and perfusion scintigraphy and CT scan of thorax were normal as well as the bone marrow and peripheral blood examination (patient's red blood cell parameters: RBC=4.62, Hb=12.2, Hct=37.8, MCV=81.8, MCH=26.4, RDW=12.7; his father: RBC=2.87, Hb=8.4, Hct=25.6, MCV=89.2, MCH=29.3, RDW=14.5).
Methods: Hb Kirklareli could not be distinguished from Hb A by electrophoresis at alkaline pH and cation exchange high-performance liquid chromatography (HPLC); at acidic pH it migrated in between Hbs S and C and in isoeletricfocusing in between Hbs A and F. The reversed phase HPLC revealed a slower extra peak (15% of the total, heme+globins) corresponding to the mutant α-chain.
Results: Direct sequencing of the α-genes revealed heterozygosis for the CAC®CTC substitution at codon 58 of the alpha$_2$-globin gene in both, patient and his father
Summary/Conclusion: To our knowledge, this is the second family reported with Hb Kirklareli. In this case the variant is not associated with iron deficiency. Neither the patient nor his father is a smoker; the father is anemic but the patient has normal Hb values. However, the patient has a long history of respiratory problems without any other cause being detected, suggesting that other studies are needed to better understand the clinical behavior of this variant and the compensatory mechanisms elicited by it.

RED BLOOD CELL'S RHEOLOGICAL PROPERTIES IN PATIENTS WITH CHOREA-ACANTHOCYTOSIS

J. Leal[1,2,*], D. Lazari[1,3], B. Neu[3], R. Brock[1], M. Adjobo-Hermans[1], G. Bosman[1]

[1]Biochemistry, Radboud University Medical Center, Nijmegen, Netherlands, [2]COBIO, National Council for Scientific and Technological Development, Brasilia, Brazil, [3]Faculty of Life Sciences, Rhein-Waal University of Applied Sciences, Kleve, Germany

Background: Functional deficits and morphological abnormalities of red blood cells (RBC) become apparent when they are subjected to biochemical or mechanical stress in vitro, or to pathological conditions in vivo. Chorea-acanthocytosis (ChAc) is a rare disease characterized by degeneration of neurons in the basal ganglia and by the presence of misshapen RBC distinguished by their thorny protrusions, named acanthocytes.
Aims: Verify the rheological properties (deformability and aggregation) of ChAc samples, comparing them to healthy controls.
Methods: The deformability and aggregation of the samples were analyzed using Lorrca®. The aggregation was also accessed via microscopy by verification of rouleaux formations.
Results: Our data on the misshapen RBC of patients with ChAc suggest that their abnormal morphology is associated with alterations in rheological properties. We have observed a decrease in the capacity to aggregate with other RBC, however, it was noticed an increase in the force needed to tease these aggregates apart. Moreover, we have measured a decrease in deformability as compared to RBC from healthy subjects.
Summary/Conclusion: The clinical implications of such alterations, in addition to oxidative and physical stress, likely not only affect the red blood cell itself but may additionally cause neuronal damage of susceptible areas in the brain due to a possible reduction in oxygen supply or clogging of the microcapillaries.

PB1976

A MUMMY EMERGES FROM THE GRAVE: SCURVY CONFOUNDING THE CLINICAL PRESENTATION OF A CHILD WITH FANCONI ANEMIA

A. Ozcan[1], S. Saracoglu[2], J.M. Verboon[3], M. Karakukcu[1], T. Patiroglu[4,*], A. Coskun[5], V.G. Sankaran[3], E. Unal[1]

[1]Division of Pediatric Hematology, Oncology & HSCT Center, Department of Pediatrics, [2]Division of Pediatric Radiology, Department of Radiology, Erciyes University, Faculty of Medicine, Kayseri, Turkey, [3]Division of Hematology/Oncology, Boston Children's Hospital, Harvard Medical School, Boston, United States, [4]Division of Pediatric Hematology, Oncology & HSCT Center, Erciyes University, Faculty of Medicine, [5]Division of Pediatric Radiology, Department of Radiology, Erciyes University, Faculty of Medicine, Kayseri, Kayseri, Turkey

Background: Scurvy is a rare disorder that can be seen in patients with severely restricted diets.[1] The last case of scurvy was reported nearly thirty-years ago in the Ethiopian refugees.[2] Scurvy diagnosis may prove challenging for physicians unfamiliar to its features, particularly in the presence of other hematologic disorders.
Aims: Here, we report a case of scurvy in a child with Fanconi Anemia.
Methods: A 10 years old female Syrian refugee was referred to Erciyes University for hematopoietic stem cell transplantation (HSCT) for Fanconi aplastic anemia (FAA) with platelet refractoriness. Blood count analyses revealed a hemoglobin of 6.3 g/dL, mean corpuscular volume of 103 fL, leukocyte count of 810x10^9/L, and platelet count of 2x10^9/L. Bone marrow aspiration and biopsy showed hypoplastic marrow with 10% cellularity. A chromosomal breakage test with diepoxybutane was consistent with FAA. Using whole exome sequencing, we identified a rare, predicted pathogenic missense variant (M-CAP score: 0.16; FANCA: p.Gly1009Asp;) According to clinical features, laboratory findings and genetic analysis she had FAA, but MRI revealed that she may also have scurvy. The serum vitamin C level was very low (0.1 mg/dL,
Results: FAA is an inherited disease characterized by bone marrow failure, short stature, skeletal abnormalities, and a high relative risk of myeloid, and epithelial malignancies due to genomic instability. Scurvy is a rare disorder that can be seen in patients with severely restricted diets. The last case

of refugees with scurvy was reported nearly thirty-years ago. The features of scurvy can confound a diagnosis of another genetic blood disorder, such as FAA. It may be speculated that the scurvy should complicate the clinical course by worsening the pancytopenia.
Summary/Conclusion: Hematologists managing patients originating from low income countries should consider factors that may confound various blood diseases such as FAA. Nutritional deficiencies can be a significant contributor to such complicated presentations

PB1977

COMPARISON OF THE EFFICACY OF PARENTERAL AND ORAL TREATMENT FOR NUTRITIONAL VITAMIN B12 DEFICIENCY IN CHILDREN

R.G. Sezer[1], H. Akoğlu[1], A. Bozaykut[1], N.N. Ozdemir[2,*]

[1]Pediatrics, Zeynep Kamil Maternity and Children's Diseases Training and Research Hospital,, [2]Pediatric Hematology Oncology, Kanuni Sultan Suleyman Education and Research Hospital, Istanbul, Turkey

Background: Nutritional vitamin B12 deficiency in children has an increasing prevalence in developing countries. Vitamin B12 deficiency is classically treated with parenteral therapy, although oral replacement is proven to be safe and effective in adult studies. There are few studies on oral replacement therapy of vitamin B12 in children.
Aims: We aimed to compare the efficacy of oral administration of vitamin B12 *versus* intramuscular vitamin B12 injections in pediatric population.
Methods: Children with serum cobalamin concentrations less than 300 pg/mL, aged between 1 months to 18 years were included in this prospective study. Children were treated either with the parenteral or oral vitamin B12. Serum samples for complete blood count and vitamin B12 levels were collected at baseline and day 30. The primary and secondary outcomes of the study were the normalization of serum vitamin B12 and hemoglobin at first month, respectively.
Results: Pre-treatment vitamin B12 increased from 183.5±47 pg/mL and 175.5±42.5 pg/mL to post-treatment value of 482±318.9 pg/mL and 838±547 pg/mL in the oral and parenteral treatment arms, respectively (p-value<0.001). Post-treatment mean values for vitamin B12 was nearly two folds higher in the parenteral group than the oral group (p-value<0.001). The number of patients who still have anemia at the 1st month of treatment were not significant in the parenteral and oral arms (p-value=0.44).
Summary/Conclusion: In this study, oral and parenteral formulations were both effective in normalizing vitamin B12 levels. We suggest that oral formulations may be considered safely as a first line treatment for vitamin B12 deficiency in children.

PB1978

INFLUENCE OF INFLAMMATORY CYTOKINES ON GENESIS OF ANEMIA IN LYMPHOPROLIFERATIVE DISORDER'S PATIENTS

T. Glazanova[1], O. Rozanova[1], N. Romanenko[2,*]

[1]clinical immunology, [2]clinical hematology, Russian research institute of hematology and transfusiology, Saint-Petersburg, Russian Federation

Background: The inflammatory cytokines (IC) play an important role in immune response to inflammation and tumor growth. Increase of their systemic level suggests the active status of immune system. However, these cytokines not only inhibit tumor growth, but can also exert myelosuppressive effect on hemopoiesis leading to development of cytopenia, including anemia.
Aims: To evaluate the influence of some IC on the development of anemia in patients with lymphoproliferative disorders (LPD).
Methods: We have examined the following groups: 1) patients with anemia (Hb 89,5±15,9 g/L; n=39) age 22-82 years, of them with II and III st. multiple myeloma-20 patients, III-IV st. Non-Hodgkin's lymphoma-8, st. chronic lymphocytic leukaemia-11; 2) healthy volunteers (Hb ≥120 g/L; n=15) age 19-76 years, as a control group. We have evaluated serum levels of the following IC: tumor necrosis factor alpha (TNF-α), interleukin-1β (IL-1β), interleukin-6 (IL-6), and interferon-γ (INF-γ).
Results: We have revealed that the level of studied IC in the group of patients was several times higher than in the control group: 1) TNF-α level in patients with anemia was 130,8±36,2 pg/ml (n=39) *vs* 42,1±13,2 pg/ml in control group (n=15), p<0,01; 2) IL-1β-484,1±66,5 pg/ml (n=30) *vs* 177,0±43,7 pg/ml (n=15), respectively, p<0,01; 3) IL-6-466,2±42,9 pg/ml (n=19) *vs* 128,0±36,5 pg/ml (n=15), respectively, p<0,01; 4) INF-γ-604,5±57,4 pg/ml (n=30) *vs* 47,7±6,6 pg/ml (n=15), respectively, p<0,0001. Correlation analysis have revealed significant associations between serum levels of TNF-α and INF-γ (r=+0,41; p<0,05; n=25), TNF-α and IL-1β (r=+0,62; p<0,01; n=18), and INF-γ and IL-1β (r=+0,49; p<0,01; n=30), suggesting their synergistic action. At the same time, there were no correlations between serum IL-6 and other listed above cytokines (p>0,05). Also there was significant negative association between Hb (reflecting the severity grade of anemia) and such cytokines as IL-1β (r=-0,46; p<0,01; n=30) and TNF-α (r=-0,58; p<0,01; n=21), indicating their negative influence on erythropoiesis, and genesis of anemia. In control group there have not been revealed any associations-either between different IC and Hb (p>0,05).
Summary/Conclusion: This study have revealed the synergistic action of TNF-α, IL-1β and INF-γ, suggesting their role in genesis of anemia of LPD.

PB1979

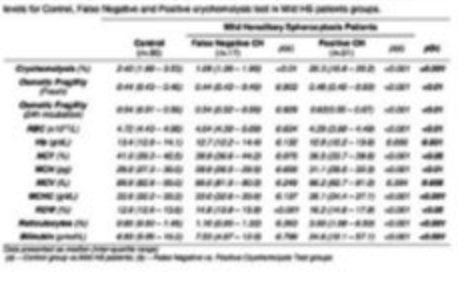
RELIABILITY OF CRYOHEMOLYSIS TEST IN HEREDITY SPHEROCYTOSIS-A PORTUGUESE POPULATION STUDY

S. Rocha[1,*], E. Cleto[2], I. Couto-Guerra[2], E. Costa[2], M.-J. Valente[1], C. Catarino[1], S. Coimbra[1,3], E. Bronze-da-Rocha[1], L. Belo[1], A. Santos-Silva[1]

[1]UCIBIO, REQUIMTE, Laboratório de Bioquímica, Departamento de Ciências Biológicas, Faculdade de Farmácia, Universidade do Porto, Porto, Portugal, [2]Sector de Hematologia Pediátrica, CHPORTO-Centro Materno-Infantil do Norte (CMIN), Porto, [3]CESPU, Instituto de Investigação e Formação Avançada em Ciências e Tecnologias Saúde (IINFACTS), Gandra PRD, Portugal

Background: Hereditary Spherocytosis (HS) is the most common non-immune congenital hemolytic anemia in individuals of northern European ancestry, ranging from an asymptomatic condition to a severe life-threatening anemia (1). HS severity is classified as Mild, Moderate and Severe according to reticulocyte count, hemoglobin (Hb) and bilirubin levels (1). Mild HS cases are more difficult to diagnose, once the complementary tests, Osmostic Fragility (OF) and cryohemolysis (CH) tests, often fail to identify less severe cases. CH was proposed as a more specific/sensitive diagnostic tool for HS however, it still gives false negative results (2).
Aims: Our aim was to evaluate the reliability of CH test in Portuguese patients previously diagnosed with HS, and to search for other biomarkers.
Methods: We studied 30 healthy individuals (matched for age and gender with patients) and 82 unsplenectomized HS patients (48 with mild, 27 with moderate and 6 with severe anemia). We performed the OF and CH tests (3); evaluated the red blood cell (RBC) count, Hb concentration, hematocrit (HCT), mean cell volume (MCV), mean cell hemoglobin (MCH), mean cell hemoglobin concentration (MCHC) and red cell distribution width (RDW) (3); reticulocyte count and bilirubin levels were also assessed (3). To evaluate differences between groups we performed the Mann–Whitney U test, as most variables presented a non-Gaussian distribution. A *p* value<0.05 was considered as statistically significant.

Table 1.



Results: For Moderate and Severe HS, CH test was an excellent diagnosis tools; however, it gave false negative results in 17 out of the 48 Mild HS patients [using the cutoff value for normal CH test (2)]. We compared data (Table 1) from control and two sets of Mild HS: False Negative and Positive CH test groups. When compared to Control, the Positive mild HS group showed significant differences for all variables, except Hb and MCV; the False Negative group presented no significant differences to control group, except a significant increase in RDW. All studied parameters were significantly different, when comparing False Negative and Positive groups, except for Hb and MCV.
Summary/Conclusion: Our data show CH test failed HS diagnosis in 35.4% of Mild HS cases, while only 10.4% of mild HS patients had a RDW lower than the cut-off reference value of 14.0% (1), suggesting that RDW deserves further studies as a useful marker for detection of Mild HS cases.

Acknowledgments: Financial support from FCT/MEC through national funds and co-financed by FEDER, under the Partnership Agreement PT2020 (UID/MULTI/04378/2013-POCI/01/0145/FERDER/007728) and Norte Portugal Regional Coordination and Development Commission (CCDR-N)/NORTE2020/Portugal 2020 (Norte-01-0145-FEDER-000024).

DIFFERENTIAL DIAGNOSIS BETWEEN UNCLEAR HEMOLITIC ANEMIA AND WILSON'S DISEASE: USE OF MULTIPLEX ALLELE SPECIFIC PCR FOR THE MOST COMMON ATP7B GENE MUTATIONS

I. Fevraleva[1,*], E. Sysoeva[2], N. Tsvetaeva[2], O. Nikulina[2], A. Sudarikov[1]

[1]Department of Molecular Hematology, [2]Department of Orphan disease, National Research Center for Hematology, Moscow, Russian Federation

Background: Wilson's disease is autosomal recessive disorder caused by mutations in copper-transporting ATPase (ATP7B). The clinical variants of the disease include isolated neurological and hepatic forms, 15% of disease cases manifest with hemolysis in the absence of autoantibodies. Confirmation of homozygous or compound heterozygous carriage of ATP7B gene mutations is essential for Wilson's disease diagnostics. Direct sequencing of a complete ATP7B gene the most reliable method of detecting mutations is still quite expensive for screening. Here we present alternative approach to the detection of polymorphisms in the ATP7B gene.
Aims: To develop screening method effective for the detection of the most common ATP7B gene mutations.

Table 1.

		Cy5 G1267R	3' Cy5-CAGACATGGGTGTGGCCATTGGCAC- BTQ2-3'

Methods: Allele-specific real-time polymerase chain reaction was optimized for the detection of common ATP7B mutations. The primers were chosen so that the last nucleotide in the forward primer chain corresponded to the normal or mutant nucleotide of the detected polymorphism. TaqMan probes were synthesized to anneal inside the amplicon behind the mutation point. PCRs on DNAs isolated from PBMC were run on Rotor-Gene instrument. Initial denaturation 300 sec. at 95°C was followed by 45 cycles of 63°C (50 sec.) and 95°C (15 sec.). The raw data was analyzed by instrument software.
Results: Primers and TaqMan probes were designed to measure HIS1069GLN, ARG778LEU, 3400delC, ARG969GLN and GLY1267ARG polymorphisms in the ATP7B gene. Probes were labeled by non-overlapping fluorescent dyes (FAM, R & G, ROX and Cy5) to facilitate multiplex detection of 5 mutations (see fig.1 for details). About 500 mutations of ATP7B gene are described so far, however, only a few of them are found frequently. HIS1069GLN homozygous mutation is responsible for 38-49% cases of Wilson's disease in the European population. Incidence of remaining 4 mutations reported not to exceed 2-3% for each. 260 patients with hemolysis or liver pathology of unknown origin admitted to National Research Center for Hematology between 2010 and 2017 years were tested using the method described and 28 patients carrying ATP7B gene mutation were found. Thirteen were heterozygous for HIS1069GLN; one heterozygous for ARG778LEU and 14 were homozygous for HIS1069GLN.
Summary/Conclusion: The test system developed is effective for the detection of most common ATP7B gene mutations and may be beneficial for the differential diagnosis between unclear hemolytic syndromes, liver pathology of unknown origin and Wilson's disease of various clinical manifestations.

PB1981

POTENTIAL UTILITY OF N-ACETYLCYSTEINE IN HEMOGLOBIN LOUISVILLE

S. De La Iglesia*, J. Gonzálvez Fernandez, C. Acosta Fleitas, L. Pérez Ortiz, L. González Pinedo, A. Sáez Salinas, T. Molero Labarta

Hematology, HUGC Doctor Negrin, Las Palmas De Gran Canaria, Spain

Background: Hemoglobin (Hb) Louisville is an unstable hemoglobin that was first described in 1971 in a Caucasian family by Keeling et at, and simultaneously in a Romanian family by Bratu *et al.*, who named this variant Hb Bucuresti. The Hb Louisville heterozygotes suffered from mild anemia with hemolytic crisis and showed a decreased oxygen affinity. In some cases, severe hemolytic reactions were produced by infections and oxidant drugs. It has been demonstrated that the antioxidant action of N-acetyl cysteine (NAC) helps improve markers of oxidative stress and hemolysis in sickle cell disease (SCD).
Aims: Since NAC is a safe, inexpensive drug, that has been used for many years for numerous indications and, as there is no other treatment that can be offered at the moment, it has been decided to try this drug in a family of patients with Hb Louisville.
Methods: Four members of the same family, who suffered from Hb Louisville, treated with NAC for the last three months (1-5), and who are still receiving the treatment till the present time. Hemoglobin, LDH and bilirubin levels were analyzed before and after the treatment started. In every visit to the hospital, the patients were asked about their quality of life and the presence of any symptoms.
Results: No adverse effects related to the drug's administration were observed. Not a single change in either hemoglobin levels or in hemolytic parameters was detected until now. Nonetheless, the patients did report a significant improvement in relation to their symptomatology. This analysis will keep on and further updated results will be presented at the European Congress.
Summary/Conclusion: Given this hemoglobinopathy's low frequency, it is extremely difficult to assemble an adequate number of cases in order to carry out a systematic study. Nevertheless, taking into consideration the absence of NAC's side effects, it seems appropriate to conclude that this drug can be offered to patients suffering from the heterozygous trait of unstable hemoglobinopathies.

PB1982

HEMOGLOBINA D-OULED RABAH, TWO CASES REPORTED IN A SINGLE CENTER

A. Pérez-Ortega*, L.M. Juárez-Salcedo, J. Arbeteta-Juanis, H. Guillén-García, A. Gil-Pérez, A. Vázquez-Ramo, D. De Miguel-Llorente

Haematology, Guadalajara University Hospital, Guadalajara, Spain

Background: Hemoglobinopathies are the most frequent monogenetic alterations. The implantation of the "heel test" as a screening method in Spain has allowed the increase of new cases diagnostics. Hemoglobin (Hb) D most frequent variant is Hb D-Punjab. Hb D-Ouled Rabah, has been only studied as an anthropological entity with few studies of clinical significance. We present the case of two family members, the father in a homozygous state for Hb D and the son in a double heterozygous state (Hb D-Ouled Rabah/Hb S).
Aims: To describe the diagnosis process and clinical features of two Hb D-Ouled Rabah carrier patients, in homozygote state and Hb D-Ouled Rabah/Hb S double heterozygote state, in our hospital.
Methods: In March 2017, a newborn is referred to our outpatient clinic, with high suspicion of an abnormal hemoglobin (Hb) diagnostic in the heel-screening test (results were compatible with a B-Thalassemia/HbS in heterozygote state). A blood test confirmed the absence of acute hemolysis signs, with complete blood counts (CBC) and biochemistry tests in normal ranges. High-performance liquid chromatography (HPLC) was executed for the patient and both parents as the first study. Electrophoresis of hemoglobin in both, acid and alkaline media was also performed with no conclusive results. In order to achieve the diagnosis, molecular biology studies were necessary. The final reports were double heterozygote for the newborn (Hb D-Ouled Rabah [β19 Asn>Lys] and Hb S [β6 Glu>Val]) and Hb D-Ouled Rabah in homozygote state [β19 Asn>Lys] for the father.
Results: The CBC reveals Hb of 12.0 g/dL, hematocrit: 32.4%, mean corpuscular volume: 90.9 fL, reticulocyte count: 1.16%. Peripheral smear showed dyanocytes. The HPLC study in the patient showed Hb A2: 45%, Hb F: 5.7% and Hb S: 39%. Patient's parents HPLC results: Father Hb A2: 77.3%, Hb F: 0.8%. Mother Result: Hb F: 0.8%, Hb A2: 3.6%, Hb S: 35%. In order to complete the study, an acidic and alkaline medium hemo-

globin electrophoresis was accomplished. In the index case, we observed an Hb S in heterozygosis without being able to determine if he was also heterozygous for Hb G or Hb D. *(Image 1)* In the father case, we observed a band corresponding with a probable Hb G or Hb D in the homozygous state without being able to discern which of the two corresponding. *(Image 2)* The mother was carrying a Hemoglobin S in a heterozygous state.Given the inconclusive results, we conducted a molecular characterization of both, newborn and father abnormal hemoglobin. In the index case, it was described as a double heterozygous for a Hemoglobin D-Ouled Rabah [β19 Asn>Lys] and a Hemoglobin S [β6 Glu>Val], in the case of the progenitor, a Hemoglobin D-Ouled Rabah was found in homozygous state [β19 Asn>Lys]. Since there is no clinical information on the management of this type of cases, we decided to use the same prevention that we use in patients with a sickle cell disease.

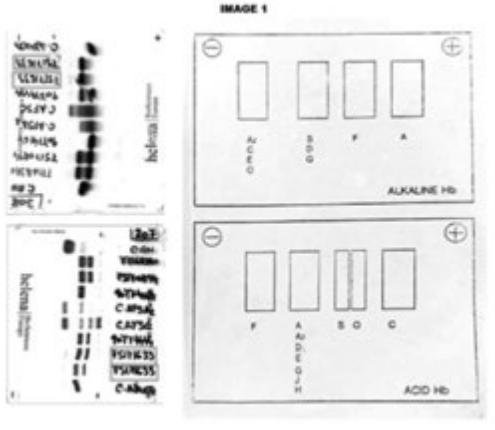

Figure 1.

Summary/Conclusion: The clinical behavior of Hb D-Punjab and Hb S in a double heterozygote state is well known but there is little knowledge about the hemolytic risk shared by Hb D-Ouled Rabah and Hb S when they occur together as in our patient. An adequate study of both electrophoresis and molecular biology in cases that are inconclusive will allow accurate diagnosis as well as an exhaustive description of the case. The monitoring of the evolution is of vital importance to predict the risk of hemolysis and acquire descriptive models to be able to use them as new cases appear.

REVIEW OF REFERENCE VALUES OF EMA-BINDING TEST

I. Hernández-Rodríguez[1,*], C. Morales-Indiano[2], J. Juncà[1], S. Vergara[3], M. Raya[3], E. Viñets[3], C. Juan[3], M. Sorigué[1], E. Orna[1], J. Grau[1], M.-A. Llopis[2], J.-T. Navarro[1], E. Feliu[1]

[1]Hematology Department., Institut Català d'Oncologia, Hospital Germans Trias i Pujol. Institut de Recerca contra la Leucèmia Josep Carreras (IJC). Universitat Autònoma de Barcelona., [2]Clinical Analysis Department, Laboratori Clínic del Barcelonés Nord i Vallès Oriental, [3]Hematology Department., Hospital Germans Trias i Pujol., Badalona, Spain

Background: Measuring the fluorescence intensity of eosin-5-maleimide (EMA) labelled red cells has been shown to be an effective screening for the detection of hereditary spherocytosis (HS), particularly in combination with acidified glicerol test or osmotic fragility test. EMA predominantly binds covalently to the ε-NH2 group of the lysine-430 in the band 3 protein of the red cell cytoskeleton. The red cells of patients with hereditary spherocytosis have a lower EMA mean channel fluorescence intensity (MFI) than normals and other haemolytic anaemias. Reference ranges according to local population must be calculated. In our experience, absolute values of MFI undergo small changes on each reagent preparation, so the difference regarding a mean of many controls acquire more signification. Reference ranges of neonatal population have not been well established.
Aims: The aim of this study was to establish the reference ranges of EMA-test in the neonatal and paediatric population, and to review the current values expected in the adult population
Methods: Twenty-three venous blood samples from 21 newborn patients (10 women and 11 men), aged from 0 to 30 days (n=19), 60 days (n=1) and 90 days (n=1) were taken from patients attended in the emergency. Only 4 of the cases were anaemic. Moreover, 33 adult patients with an EMA test performed were reviewed. Other tests were considered, such as acidified glycerol test, osmotic fragility test and RBC membrane protein quantification by SDS-PAGE electrophoresis, to establish a final diagnosis of HS. Five microliters of whole blood from each sample was washed with 0.9% NaCl solution and incubated in darkness at room temperature for 1 h with 25 μL of EMA dye (0.5 mg/mL, in phosphate-buffered saline, PBS), with intermittent mixing. Stained red blood cells were washed three times using 0.5%/FBS/PBS and centrifuged after each wash. Cells were suspended in 500 μL of 0.5% FBS/PBS solution, and 100 μL of labelled cell suspension was diluted in 1.4 mL of FBS/PBS. Flow cytometric analysis was carried out using Cytomics FC 500 flow cytometer (Beckman Coulter, Fullerton, CA, USA). Blood samples from six blood donors were used as normal controls for each assay. The reference interval was calculated according to the CLSI guidelines, C28-A3 and a robust method was used.
Results: Reference 95% interval for newborn patients was -33.5 to 17.9, ranging from a very negative value to an almost normal adult value. Reference intervals for adult individuals were changed from those recommended in the literature (difference >16% suspected HS, and difference >21% compatible with hereditary spherocytosis) to 11% and 16%, respectively. Details of each case will be provided.
Summary/Conclusion: Reference interval for newborn patients has a wide range. Studies on HS newborns must be conducted to establish the range of suspected HS. Adult reference interval for older children and adults should be calculated for each local population, as it may differ significantly from the original recommendations.

PB1984

CEFTRIAXONE-INDUCED HEMOLYTIC ANEMIA IN A CHILD SUCCESSFULLY MANAGED WITH INTRAVENOUS IMMUNOGLOBULIN: CASE REPORT

U. Aygüneş*

Pediatric Hematology-Oncology, Cumhuriyet University Faculty of Medicine, Sivas, Turkey

Background: Ceftriaxone is a frequently used empiric antibiotic in children. Acute hemolysis is a rare side effect of ceftriaxone therapy associated with a high mortality rate.
Aims: Here, we report successful management of life-threatening ceftriaxone-induced hemolytic anemia (CIHA) in a previously healthy 5-year-old girl. We also reviewed the literature of hemolytic anemia. Careful observation is required for pediatric patients receiving ceftriaxone.
Methods: A 5-year-old female was transferred to our hospital for further treatment of a sudden episode of macroscopic hematuria, hemoglobinuria, and hemolytic anemia that developed after being given fifth dose of ceftriaxone. The previous week, she had complained of a cough and fever and had been diagnosed with tonsillopharyngitis. She had been treated with ceftriaxone (100 mg/kg/day intravenously) for 2 days as an outpatient at another center. Her symptoms worsened and the fever persisted for 3 days. Her blood tests were checked on the third day. The complete blood count included hemoglobin 11.1 g/dl, hematocrit 30%, white blood cell count 18180/μl, and platelet count 519000/μl. She was hospitalized and continued on IV ceftriaxone. She had sudden-onset pallor, fatigue, and hemoglobinuria within about 30 minutes of starting the fifth dose of IV ceftriaxone. On admission to our hospital, she was unconscious and was transferred to our pediatric intensive care unit. Her vital signs were heart rate 154/min, respiratory rate 26/min, temperature 37.0°C, and blood pressure 90/60 mm Hg. The spleen was palpable 1 cm below the costal margin. She was given IV fluids and the initial laboratory tests revealed severe anemia with hemoglobin (Hb) 3.8 g/dl, hematocrit 11.1% and reticulocyte count was 3.82%. The peripheral blood smear was consistent with 4 (+) hemolysis, having schistocytes. The blood chemistry revealed indirect bilirubinemia (3.89 mg/dl; normal range: 0.3-1.1) and elevated lactate dehydrogenase (1257 U/l; normal range: 125-250). The haptoglobin level was<6.54 (normal 30–200) and Coombs' direct antiglobulin test was positive for IgG (3+) and for C3d (3+). The reddish urine was 4 (+) for hemoglobin. CIHA was diagnosed and the ceftriaxone stopped. The patient was treated with red blood cells (10 ml/kg), high-dose immunoglobulin (1 g/kg). She improved quickly and her Hb increased from 3.8 to 7.3 g/dl. Her Hb did not drop again nor did she develop acute tubular necrosis. She was discharged on the tenth hospital day with Hb 12.7 g/dl and normal blood chemistry.
Results: The patient had no further hemolytic episodes. Her hematocrit remained stable over the following 3 months and direct antiglobulin test is still 1 (+).
Summary/Conclusion: Ceftriaxone is used very frequently in children; an early diagnosis and proper treatment of hemolytic anemia are essential to improve the patient outcome. The pathophysiological mechanism is the same as for non-drug autoimmune hemolytic anemia. However, there is still

no consensus treatment for CIHA. Intravenous immunoglobulin can be used in clinical emergencies, such as our case, or in refractory cases.

PB1985

SERUM AND RED CELL FOLATE LEVELS AMONG LOW BIRTH WEIGHT NEONATES IN WAD MADANI OBSTETRICAL AND GYNAECOLOGICAL TEACHING HOSPITAL,GEZIRA STATE,SUDAN (2016)

A. Khadir*, A.E. Mustafa

Haematopathology, Faculty of medicine, Gezira university, MEDANI, Sudan

Background: A central feature of embryonic and fetal development is widespread cell division; folate is central because of its role in nucleic acid synthesis. During gestation folate deficiency can impair cellular growth and replication in the fetus or placenta. Low birth weight is closely associated with inhibited growth and cognitive development, and chronic diseases later in life. Many researches found a relationship between umbilical cord folate status and intrauterine growth restriction. In sudan no similar study was found.
Aims: It was a case-control study aimed to measure folate levels among groups of normal and low birth weight neonate to evaluate the correlation between umbilical cord folate levels and birth weight.
Methods: Haematological parameters were measured using automated cell counter,microscopic examination of peripheral blood smears and reticulocytes preparations. Serum and red cell folate were measured by electrochemiluminscence technology (cobas e 411 analyzer). Statistical analysis was done using SPSS program version 20.
Results: From the study it was found that umbilical cord RBC folate status to be an important predictor of neoborn birth weight, with increasing cord RBC folate being associated with increasing neoborn birth weight. Statistically significant association was found between red blood cell folate levels and birth weight (P value of 0.047 in case group). Thirteen out of 43 cases had low red cell folate levels. This indicates the presence of relationship between folate levels in fetus and birth weight. No statistically significant association was found between levels of serum folate and birth weight in the case group (P Value 0.59 in case group). This may be due to fact that serum folate is a marker of recent dietary intake and it is subjected to prandial variation.
Summary/Conclusion: Red blood cell folate is considered the most reliable biomarker of folate status, as it reflects tissue folate stores. A single measurement of serum/plasma folate reflects only the time of blood collection and cannot differentiate between occasional low dietary intake of the vitamin and folate deficiency. Our study revealed that there is clear association between folate deficiency and increase incidence of low birth weight and preterm delivery.

UMBILICAL CORD-DERIVED MESENCHYMAL STROMAL CELLS PROCESSED WITH SERUM FREE CULTURE AND CRYOPRESERVATION FOR CLINICAL APPLICATION OF SEVERE ACUTE GVHD

T. Nagamura-Inoue[1,*], A. Takahashi[1], T. Shimazu[1], A. Hori[1], T. Mukai[1], M. Okada[1], F. Nagamura[2], A. Tojo[3]

[1]Department of Cell Processing And Transfusion, Research Hospital, The Institute of Medical Science, The University of Tokyo, [2]Division of Advanced Medicine Promotion, [3]Division of Molecular Therapy, Advanced Clinical Research Center, The Institute of Medical Science, The University Of Tokyo, Tokyo, Japan

Background: Recently, umbilical cord (UC) has become attracted source of mesenchymal stromal cells (MSC) for the treatment of severe acute graft *versus* host disease (aGVHD), because of abundant sources and ease of collection without invasive process for the donor and low immunogenicity with immunosuppressive ability. In addition, because supplemented fetal bovine serum (FBS) in the medium with which UC-MSCs are cultured introduces the possibility of xenogeneic antigens and infections including bovine spongiform encephalopathy (BSE), lower antigenic and safer medium is needed for clinical use.
Aims: We recently established the serum-free culture and cryopreservation in UC-MSC processing. Objectives of this study were to evaluate UC-MSC cultured with serum-free medium and cryopreserved in serum-free cryoprotectant for the treatment of severe acute GVHD.
Methods: UC tissue was cut and cryopreserved with serum-free cryoprotectant, STEM-CELLBANKER. Master UC-MSCs (P1) were isolated from frozen-thawed UC by an improved explant method. The master UC-MSCs were cryopreserved once and thawed and expanded until P4 in serum-free RM medium (Rohto Pharmaceutical Co.,Japan). Product cells were collected followed by automated concentration and washing instrument produced by Kaneka Co., Japan. The product cells were cryopreserved in DBA-D solution consisted of dextran-40, Bicarbonate ringer, Citrate buffer, and 10v/v% DMSO. Mixed lymphocyte reaction (MLR) assay co-cultured with or without UC-MSCs was carried out using responder mononuclear cells stained with CFSE, and analyzed by flowcytometry.
Results: UC-MSC cultured with RM medium showed significantly higher proliferation ability compared with those with 10% FBS and MEM. The UC-MSCs were positive for CD105, CD73, CD90, and negative for CD45 and HLA-DR. HLA-DR, CD80, CD86, and CD40 were negative even in the high concentration of IFN-γ, while BM-MSCs became positive for HLA-DR. PD-L2 was constitutively expressed in UC-MSC, while PD-L1 was induced by the addition of IFN-γ. In MLR, responder T cell proliferation triggered by allogeneic dendritic cells was inhibited efficiently by 3rd party derived UC-MSCs.In the presence of the transwell insert, the inhibitory effect of UC-MSC was not the same degree as when there was direct contact between UC-MSCs and activated T cells. Realtime-PCR revealed the induction of IDO only in the co-cultured with UC-MSC and MLR.
Summary/Conclusion: These results demonstrated that UC-MSCs cultured with serum-free medium and cryopreservation, have high proliferation potency with immunosuppressive effects. UC-MSC may be a feasible alternative source to BM-MSC for immunosuppressive therapy in severe aGVHD.

PB1987

A MATHEMATICAL MODEL DESCRIBING THE RELATIONSHIP BETWEEN GENETICALLY-MODIFIED HEMATOPOIETIC STEM CELL TRANSPLANT AND RESULTING BLOOD HEMOGLOBIN (HB) LEVELS IN BETA THALASSEMIA

T.W. Ho[1,*], A.S. Lundberg[1], R. Blanchard[1], W. Denney[2]

[1]CRISPR Therapeutics, [2]Human Predictions, LLC, Cambridge, United States

Background: Beta thalassemia is a genetic blood disorder characterized by reduced red blood cell (RBC) lifespan, low blood hemoglobin and the need for lifelong transfusion. CTX001 is a gene-edited cellular therapy for the treatment of beta thalassemia, in which autologous hematopoietic stem cells (HSCs) have been edited to disrupt the erythroid enhancer region (EER) of BCL11a on chromosome 2. Treatment with CTX001 is intended to increase expression of fetal hemoglobin (HbF) in RBCs. CTX001 is being co-developed by CRISPR Therapeutics and Vertex Pharmaceuticals.

Aims: A mathematical model was developed to describe the relationship between a dose of genetically modified HSCs and resulting blood Hb following engraftment.
Methods: Literature and original research data were used to develop a model comprised of distinct biological processes characterizing the effect of gene editing on HbF in the RBC, the proportion of modified HSC administered, bone-marrow engraftment of HSCs, surviving RBC in circulation, and, finally, an estimate of blood Hb levels. Individual components included the ratio of gamma/alpha globin mRNA, RBC survival post ablation, lifespan of RBCs as a function of globin protein ratios (alpha-partner/alpha globin) and extrapolation of RBC lifespan to Hb. The relationship between dosing and Hb was evaluated across a range of input variables. Data were manually extracted from literature sources with individual-level data reported on endpoints relevant to the models (Ferrari, 2017; Vigi *et al.*, 1969; Clegg *et al.*, 1979). The input data were independently quality controlled. R with the rstanarm library was used to generate mathematical models using Bayesian inference and minimally-informative priors. Models were selected to represent the data available and were a combination of linear fixed effect, linear mixed effect, and nonlinear fixed effect models. The best model was determined by statistical properties and visual checks of the analysis results.
Results: RBC lifespan, as measured by ^{51}Cr pulse, appears directly and linearly related to alpha-partner/alpha globin ratio (Vigi *et al.* 1969). Original research data indicated that CRISPR modification of the BCL11a EER increased the gamma/alpha globin mRNA ratio. Efficiency of transfection (% cells transfected) was modeled as a variable process without covariates. A linear mixed effects model estimated that the percent of leukocytes in blood emanating from transfused HSCs is 77.3% [50.1, 105, 95% credible interval] x the efficiency of gene modification in the HSCs. When the alpha-partner/alpha globin ratio is 1, the RBC half-life is estimated to be 29.4 [27.3, 31.6] days consistent with the normal ^{51}Cr pulsed RBC half-life in subjects without beta thalassemia. When no alpha partner is present, the estimated lifespan is 0.522 [-0.935, 1.80] days, aligning with expectations that alpha partners are required for RBC survival. Using these models and internal data on the distribution of alpha-partner/alpha mRNA and protein ratios in reticulocyte-like cells, the model estimate for the alpha-partner/alpha ratio is 0.746 following bi-allelic genetic modification of HSC cells (CTX001). The estimated ratio would suggest an average ^{51}Cr pulsed RBC lifespan of 21 -34 days, depending on assumptions for maximum RBC lifespan constraints.
Summary/Conclusion: Simulations across the model suggest that the proportion of biallelically modified HSCs must be 20 to 50% for notable improvement in blood Hb levels (target 10 g/dL) following treatment with CTX001.

DETECTION AND STUDY OF MOSAIC RUNX1 MUTATION IN POST AML CR SAMPLES USING HIGHLY SENSITIVE DDPCR

K.D. Johansen[1,*], H. Hasle[2], L.H. Ebbesen[1], A. Aggerholm[1]

[1]Department of Hematology, [2]Department of Pediatrics and Adolescent Medicine, Aarhus University Hospital, Aarhus, Denmark

Background: The RUNX1 gene encodes a transcription factor and is a key regulator in the development of normal hematopoiesis. Somatic *RUNX1* mutations are recurrent in malignant diseases including myelodysplastic syndromes (MDS), acute myeloid leukemia (AML) and germline *RUNX1* mutations are associated with Familial platelet disorder with predisposition to AML (FPD/AML). In this study we analyzed serial samples from a 10-year-old girl with prolonged thrombocytopenia post AML treatment for a constitutional *RUNX1* mutation. A remission PB sample 510 days post AML diagnosis was investigated by targeted NGS and showed a *RUNX1* c.347T>C (p. F116S) mutation which was detected at a variant allele frequency (VAF) of 6%.
Aims: Establishment of a ddPCR assay for detection of a mosaic *RUNX1* mutation and exploration of its longitudinal evolution and presence in different hematopoietic cell lineages.
Methods: A droplet digital PCR (ddPCR) assay was designed for detection of the *RUNX1* c.347C>T mutation. Primers and HEX/FAM labeled probes were designed for detection of both mutant and wild type DNA. The assay sensitivity was experimentally validated to be 0.1%. For sequential studies DNA was isolated from peripheral blood (PB) and bone marrow (BM) remission samples. T-cells, B-cells, and myeloid cells were isolated from PB with CD3, CD19, and CD15 antibodies respectively using EasySep™ reagents from Stem Cell Technology. Fibroblasts and keratinocytes from a skin biopsy were cultivated for further analysis, and DNA from the patient's Guthrie card was extracted.
Results: Fibroblasts and keratinocytes from the skin biopsy were found to be negative for the *RUNX1* mutation. While positive for *GATA2* and double *CEBPA* mutations at AML diagnosis no *RUNX1* mutation could be detected in the diagnostic sample. In sequential analyses of PB and BM post AML the mutation was seen for the first time in PB 419 days post AML with a VAF of 0.2%, increasing to 13% and 23%, over the next 400 days (figure). Analyses of T-cells, B-cells, and myeloid cells isolated from a PB remission sample 845 days post AML diagnosis showed presence of the *RUNX1* mutation in all three lineages with allele frequencies of 4%, 32%, and 8% respectively.

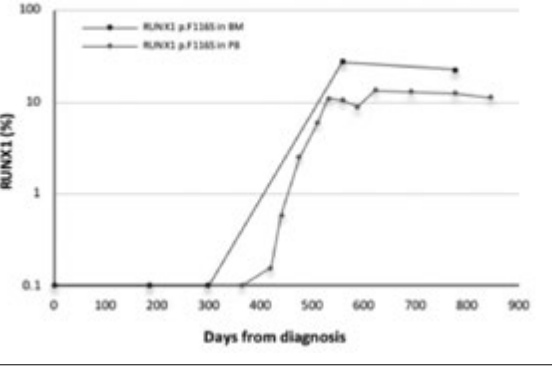

Figure 1.

Summary/Conclusion: The *RUNX1* mutation identified was excluded as being germline due to its absence in fibroblast and keratinocytes from skin. Using ddPCR we were able to detect the mutation in T-cells, B-cells, and myeloid cells meaning that the mutation has originated in a hematopoietic stem cell. The patient was reported to have had a lifelong tendency to easy bruising and it is tempting to speculate that the mutation occurred in the hematopoietic system during embryonic development. However, we were not able to detect the mutation in DNA from patient's Guthrie card and have no other PB samples prior to the AML diagnosis. If the *RUNX1* mutation is responsible for the reported easy bruising and post AML thrombocytopenia, it must arise from another hematopoietic stem cell than those leading to the AML. Another possibility is that the *RUNX1* mutation is therapy induced and possesses a proliferative advantage compared to normal stem cells. Future fluorescence activated cell sorting of normal and

leukemic hematopoietic stem cells from the diagnostic AML sample and subsequent *RUNX1* ddPCR analysis will hopefully aid us in determining the occurrence of the mutation.

PB1989

CORD BLOOD STEM CELLS EXPANSION IN THE MICROFLUIDIC DEVICE UNDER THE INFLUENCE OF NICOTINAMIDE

M. Asgari*, M. Nikougoftar

Cord Blood Bank, Iran Blood Transfusion Organization, Tehran, Iran, Islamic Republic Of

Background: The low number of umbilical cord blood cells is an important barrier to successful bone marrow transplantation. Therefore, the growth of these cells while maintaining their functional characteristics is of great importance. Using microfluidic technology as well as culturing cells on 3D scaffolds like DBM has greatly contributed to the simulation of the mechanical and chemical micro-environment of the bone marrow tissue. There are also specific compounds for proliferation without differentiation of cells, one of them is nicotinamide
Aims: In the study we aimed to expand hematopoietic stem cells by nicotinamide and in the 3D scaffold (DBM) under the effect of microfluidic device.
Methods: hematopoietic stem cells(HSCs) were cultured 7 days in two groups: 1. In DBM in the microfloid device 2. In DBM in static state (control), under the following conditions: 1.negative control 2.cytokine 3.nicotinamide 4.nicotinamide+cytokine 5.negative control with feeder 6.cytokine+feeder 7.nicotinamide+feeder 8.nicotinamide+cytokine+feeder After 7 days, cell count, their purity using flow cytometry, Colony forming unit assay and apoptosis were evaluated. The status of the cells on the scaffold was observed using electron microscopy
Results: Our results indicated that more cells were counted in static culture than microfluidic culture (perfusion), while the ability of cell colonization in microfluidic culture was far higher. The purity of HSCs was higher in microfluidic culture, and fewer cells entered the apoptotic phase. In all cases, the combination of nicotinamide and cytokine in the presence of feeder, was accompanied with more proliferation, more CD34 + cells, less apoptosis, and higher colonyforming ability than other groups.
Summary/Conclusion: Nicotinamide by preventing epigenetic changes resulting from laboratorial cell culture and microfluidic device associated with DBM by simulating bone marrow niche is a very suitable compound for the development of these cells.

Background: Although familial hemophagocytic lymphohistiocytosis (FHL) can manifest with combination of unremitting fever, hepatosplenomegaly and pancytopenia, FHL should be considered in unusual initial presentations. Although familial hemophagocytic lymphohistiocytosis (FHL) can manifest with combination of unremitting fever,hepatosplenomegaly and pancytopenia, FHL should be considered in unusual initial presentations.
Aims: Familial hemophagocytic lymphohistiocytosis should be considered in unusual initial presentations.
Methods: We present three cases with FHL with two novel mutations with different initial presentations.
Results: The first patient has a homozygous UNC13D stop-gain (c.2650C>T.p.Gln884Ter) mutation and presented at the age of 21 months with seizures and hyperintense signal changes on T2-weighted and T2-fluid attenuated inversion recovery magnetic resonance imaging (MRI) which was thought to be central nervous system involvement. Also she had macular widespread body rush and fever which was ongoing for six months. The patient responded to the HLH-2004 protocol, and allogenic hematopoetic stem cell transplantaon was planned from her healthy sister. The second and third patients were siblings that carried a homozygous STXBP2 splice-site mutation (c.430-1G>A), and presented in infancy with fatal sepsis and hyperferritinemia, yet without full clinical features of HLH. The first patient has a homozygous UNC13D stop-gain (c.2650C>T.p.Gln884Ter) mutation and presented at the age of 21months with seizures and hyperintense signal changes on T2-weighted and T2-fluid attenuated inversion recovery magnetic resonanceimaging (MRI) which was thought to be central nervous system involvement. Also she had macular widespread body rush and fever-which was ongoing for six months. NEONATAL LYMPHOPENIA SCREENING FOR DIAGNOSIS OF COMBINED IMMUNODEFICIENCY: SINGLE CENTER STUDY

T. Patiroglu[1,*], M. Cansever[2], A. Poyraz[3], I. Muderris[3]

[1]Pediatric Hematology, [2]Pediatric Immunology, [3]Pediatric, Erciyes University Medical Faculty, Kayseri, Turkey

Background: Combined immunodeficiency (CID) is a primary immunodeficiency diseases with severe loss of T and B lymphocyte function. Lymphopenia is an important finding in diagnosis of CID.
Aims: We planned the screening of lymphopenia in cord blood samples during labor for diagnosis of CID.
Methods: Complete blood count (CBC) was measured in cord blood sample of every baby born in our hospital from january to december 2018. If lymphocyte count was below 3000/mm3, it was accepted as neonatal lymphopenia. Immunological investigations including serum immunoglobulin levels, lymphocyte subgroups and chest radiography for thymus shadow were evaluated in newborns who had lymphopenia.
Results: In this study, CBC was measured in 1500 cord blood samples during labor and lymphopenia was found in 39 of them. Mean lymphocyte count was calculated as 2250/mm3 (range:1550-4400). Two of 39 newborns with lymphopenia had CID according to immunological investigations. One patient with CID had RAG 1 defiency. It is expected the result of genetical analysis of other patient with CID.
Summary/Conclusion: The lymphopenia can occur may included infectious,genetic, systemic and iatrogenic causes. Early diagnosis of CID can be life saving, so that neonatal screening of lymphopenia is important for early diagnosis of CID.

Background: Fanconi anemia (FA) is an autosomal recessive genetically transmitted hereditary disease which predisposes the patient to progressive bone marrow failure, growth retardation, leukemia, and solid tumors. In nearly

50% of the children with FA, skeletal anomalies are found. Approximately 70% of them are upper extremity anomalies. The most frequently encountered problems are observed along the thumb-side, and radial edge of the forearm. Besides, much information is not available on wrist bones (proximal, central, and distal rows) and relevant anomalies in patients with FA.
Aims: We wanted to present wrist bone anomalies which we evaluated in 78 cases together with literature information.
Methods: Seventy-five cases with the diagnosis of FA followed up by 12 Departments of Hematology-Oncology from 9 different cities were evaluated by a single radiologist based on criteria defined in *Greulich Pyle Hand Wrist Atlas Radiology*, and changes of hand-wrist bones of all cases aged between 15 months, and 27 years were determined.
Results: Demographic characteristics, and hand-wrist bone anomalies of all cases were determined, and tabulated. Wrist bones belong to a group of short bones. Congenital anomalies may be embryologically classified in the "underdevelopment group." Embryogenesis of the upper extremity develops from lateral edge of the embryo at 4. week after fertilization. At 8. week of the fertilization, formation of all extremities is completed.
Summary/Conclusion: In the radiologic, endocrinologic, and orthopedic evaluation, and interpretation of wrist radiograms, the abovementioned signs, and symptoms of this disease should be also investigated.

PHENOTYPIC CHARACTERIZATION OF CIRCULATING T AND NK CELLS IN HODGKIN LYMPHOMA (HL) PATIENTS IN RELATION TO TUMOR BURDEN

T.A. Mulder[1,*], K. Heimersson[1], B. Näsman-Glaser[1], L. Hansson[1,2], M. Palma[1,2]

[1]Department of Oncology-Pathology, Karolinska Institute, [2]Department of Hematology, Karolinska University Hospital, Stockholm, Sweden

Background: In classical Hodgkin lymphoma (cHL), the malignant Reed-Sternberg (HRS) cells usually represent only 0.1% to 2% of cells in the affected lymph nodes. These cells are embedded in an inflammatory microenvironment, dominated by lymphocytes and other immune cells that support their survival and growth. Conversely, the HRS cells orchestrate the immune cell infiltrate in their own favour through complex interactions.
Aims: To characterize the phenotype of lymphocytes in the peripheral blood of cHL patients with different clinical characteristics and in comparison to healthy individuals.
Methods: Peripheral blood samples were obtained from 36 cHL patients at diagnosis. Eighteen patients had limited-stage (I-IIA) and 18 had advanced-stage (IIB-IV) disease. Twenty sex- and age-matched healthy individuals were included as controls. Patients with nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL), ongoing acute Epstein-Barr virus infection and positive serology for human immunodeficiency virus were excluded. Cells from whole blood and the peripheral blood mononuclear cell (PBMC) fraction were analysed by flow cytometry. Absolute numbers of lymphocyte subsets were derived by dual-platform counting technologies.
Results: No significant difference was observed in absolute lymphocyte counts between cHL patients and healthy controls (median 1.60 $x10^9$/L and 1.45 $x10^9$/L in limited and advanced disease pts, respectively, *vs* 1.70 $x10^9$/L in controls). Lower numbers of naïve CD8+ T cells were observed in cHL pts compared to controls (median 0.11 $x10^9$/L in limited disease *vs* 0.10 $x10^9$/L in advanced *vs* 0.23 $x10^9$/L in controls, p=0.02 and p=0.001, respectively). Limited-stage patients had higher numbers of the antigen-experienced CD8+ T cell subsets CD45RA-CCR7- (median 0.07 *vs* 0.05 $x10^9$/L, p=0.01) and CD45RA+CCR7- (median 0.22 *vs* 0.14 $x10^9$/L, p=0.04). Limited-stage patients also had higher numbers of CD69+ (median 0.054 *vs* 0.028 $x10^9$/L, p=0.001) and PD-1+ (median 0.13 *vs* 0.08 $x10^9$/L, p=0.007) CD8+ T cells. Limited-stage (n=3) as well as advanced-stage patients (n=4) also had higher numbers of PD-1+TIM-3+ double-positive T cells than controls (n=7) (median 0.082 (p=0.02) *vs* 0.12 (p=0.006) *vs* 0.077 $x10^9$/L, respectively). Moreover, both limited-stage and advanced-stage patients had higher numbers of Ki67+ CD4+ T cells (median 0.015 (p=0.008) *vs* 0.015 (p=0.04) *vs* 0.008 $x10^9$/L, respectively) and CD8+ T cells than controls (median 0.009 (p=0.01) *vs* 0.010 (p=0.005) *vs* 0.004 $x10^9$/L, respectively). As for the NK cells, the total number in peripheral blood of advanced-stage patients was lower than that of controls (median 0.14 *vs* 0.20 $x10^9$/L, p=0.01). On top of that, advanced-stage patients (n=5) had a smaller fraction of NK cells that were double-positive for NKG2D and DNAM-1 than controls (n=7) (median 71.6 *vs* 93.4%, p=0.01).
Summary/Conclusion: In addition to the tight control that HRS cells seem to have over the immune cells in their tumour microenvironment, they might also influence circulating lymphocytes. Indeed, cHL patients had reduced amounts of naïve CD8+ T cells. This, in patients with limited disease, was associated with an increase in antigen-experienced and chronically activated CD8+ T cells. Moreover, cHL patients had an increased amount of proliferating CD4+ and CD8+ T cells irrespective of disease stage. Finally, advanced-stage cHL patients also had lower numbers of NK cells which seemed to express activating receptors to a lower extent than healthy controls. Further studies are ongoing to characterize these findings in depth.

PB1995

EPSTEIN-BARR VIRUS EXPRESSION IN HODGKIN'S LYMPHOMA IN SUDAN

E. Hussein[1,2,*], A.M. EL Hassan[2], S.M. Bakhiet[2]

[1]Haematology and Immunohaematology, Faculty of Medical Laboratory Sciences, University of Khartoum, Sudan, [2]Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan

Background: Hodgkin's lymphoma (HL) is a potentially curable malignant lymphoma with distinct histology, biologic behavior, and clinical characteristics. Epstein Barr- virus (EBV) has remained the main candidate suggested as the infectious agent causing Hodgkin's lymphoma for many years. To our knowledge, in The Sudan, no previous study was performed to associate Hodgkin's lymphoma to infectious agents. In particular, no data available about the prevalence of EBV in HL, nor the variability among different HL pathological subtypes. It is important to stress that infectious agents are so common in in The Sudan as one of the developing countries.
Aims: To screen the paraffin embedded lymph nodes for the presence of Epstein Barr virus genome in Hodgkin's lymphoma cases compared to reactive lymphadenitis controls.
Methods: This is a retrospective case control study. All cases of HL were first confirmed histologically and the difficult ones were further immunohistochemically confirmed. Genomic DNA was extracted from formalin fixed paraffin embedded lymph nodes using commercial DNA extraction Kits, followed by PCR amplification of three different genes (LMP 1, EBNA1 and IR3 region), using three different sets of specific primers. Amplified DNA was then visualized after agarose gel electrophoresis.
Results: Forty-one cases were enrolled, 25 (61%) of them were males and 16 (39%) were females with 1.6/1 male to female ratio. The mean of age was 30 years for both males and females. Fifty-nine percent of patients were either children or young adults of less than thirty years old. HL cases were examined for histology and immunohistochemistry and accordingly, classified as 23 (56%) cases of mixed cellularity (MC) (**Fig.1**), 16 (39%) cases of nodular sclerosis (NS) (**Fig.2**), one case (2.4%) of each of lymphocyte predominance (LP) and lymphocyte depletion (LD). EBV genome was detected in approximately half (51%) of HL patients (P value=0.035) and 18.8% of reactive lymphadenitis controls (**Fig.3**, **Fig,4**). EBV virus was much more expressed in Mixed cellularity HL subtype compared to other subtypes as the virus was detected in 13 cases of Mixed Cellularity and 7 cases of Nodular Sclerosis (**Fig.5**).
Summary/Conclusion: EBV virus is associated with approximately half of Hodgkin's lymphoma cases in Sudanese enrolled in this study and particularly associated with the Mixed Cellularity subtype. Further perspective study is highly recommended to investigate the involvement of EBV in pathogenesis of Hodgkin's lymphoma in Sudanese and whether it can be used for future targeted therapeutics.

Hodgkin lymphoma – Clinical

PROGNOSTIC SCORES IN HODGKIN LYMPHOMA (HL): COMPARISON OF THE IPS AND THE GHSG SCORE IN AN UNIFORMLY TREATED COHORT

M. Fevereiro*, C. Gaspar, S. Gonçalves Pereira, M. Lemos, A. Botelho De Sousa

Hospital dos Capuchos, Lisboa, Portugal

Background: The International Prognostic Score (IPS), which was introduced and validated 2 decades ago by Hasenclever and Diehl for advanced stages, is the most widely used risk stratification tool in HL. However, it has been criticised for its low validity in early bulky disease and modest predictive power in unfavourable disease. In the present era, with more than 80% of patients (pts) cured by first-line treatment, we need an easy-to-apply and accurate index to help deciding risk-adapted approaches. The German Hodgkin Study Group (GHSG) proposed an alternative score, which has not yet gained broad acceptance.
Aims: We retrospectively compared the influence of the IPS and the GHSG score on overall survival (OS), event-free survival (EFS) and relapse rate (RR) in an uniformly treated cohort in our center.
Methods: From Jan/97 to Dec/16, 292 consecutive pts with classical HL (80% nodular sclerosis) were treated with Stanford V. Median age was 32 (15-72), 35% had advanced stage disease and 39% had bulky mediastinal disease (all of whom received radiotherapy). The IPS was low-risk in 56%, intermediate-risk in 33% and high-risk in 11%. By the GHSG classification, 18% were early favourable, 33% early unfavourable and 49% advanced; the differences in distribution were significant ($p<0.01$).
Results: Overall response rate was 95%. With a median follow up of 9.5 years, median OS is not yet reached. OS at 12 years varied from 89 to 47% in IPS groups, and from 87 to 54% in GHSG groups ($p<0.05$ for all comparisons). EFS varied from 74 to 34% for IPS and from 75 to 58% for GHSG ($p<0.05$). RR was similar in low and intermediate-risk IPS (23 *vs* 26%) and was 35% in high-risk IPS; in GHSG groups it was 15%, 22% and 31% respectively. The IPS was a better discriminator than the GHSG score for OS (AUC 0.69 *vs* 0.63, p=0.005) and EFS (AUC 0.61 *vs* 0.60, p=0.006).
Summary/Conclusion: The distribution of pts by IPS and GHSG score showed significant differences in our cohort, with an inversion of low and high-risk groups. This discrepancy is attributable to the high proportion (39%) of bulky mediastinal disease in our series, which is also the probable cause of a paradoxically high RR in the low-risk IPS group. The prognostic performance of the GHSG score was not superior to the IPS, reinforcing the need to evolve beyond clinical scores and to incorporate novel biomarkers into clinical practice, in order to accurately identify pts wirh the poorest risk.

PB1997

PROGNOSTIC SIGNIFICANCE OF NEUTROPHIL LYMPHOCYTE RATIO (NLR) IN NODULAR LYMPHOCYTE PREDOMINANT HODGKIN LYMPHOMA (NLPHL)

S. Paydaş[1,*], I. Barista[2], M. Dogan[3], M. Pehlivan[4], G. Seydaoglu[5], S. Lacin[6], A. Unal[7], B. Yildiz[8], O. Arslan[9], M. Ozcan[9], I. Gullu[6], S. Bilgin[4], N. Keni[7], Z. Baslar[4], N. Karadurmus[8], H. Ozsan[10], M. Yagci[11], H. Akbulut[12]

[1]Medical Oncology, Cukurova University, Adana, [2]Medical oncology, Hacettepe University, [3]Medical Oncology, Ankara Numune Hospital, Ankara, [4]Hematology, Istanbul University, Istanbul, [5]Biostatistics, Cukurova University, Adana, [6]Medical oncology, Hacettepe Univesrity, Ankara, [7]Hematology, Erciyes University, Kayseri, [8]Medical Oncology, GATA, [9]Hematology, Ankara University, Ankara, [10]Hematology, Dokuz Eylül University, Izmir, [11]Hematology, Gazi University, [12]Medical Oncology, Ankara University, Ankara, Turkey

Background: NLPHL accounts for 5% of HL cases and its biology is different from classical HL (cHL). It has an indolent course, propensity for multiple and late relapses and high grade lymphomas. For this reason prognostic parameters are very important for risk adapted treatment strategy.
Aims: The aim of this study is to determine the prognostic significance of neutrophil lymphocyte ratio (NLR) which is an important inflammation parameter beside the known prognostic parameters such as sex, age, stage IV disease, serum albümin, low hemoglobin, leukocytosis, and lymphocytopenia used in cHL.
Methods: 75 cases were retrospectively evaluated. Female/male ratio was 20/55. Albumin level<4g/dl, hemoglobin<12g/dl, high WBC >10.10^9/L and lympho-

cytopenia <1x10^9/L were evaluated as poor prognostic indicators. Eleven cases had been treated by radiation alone, 32 had been treated by chemotherapy, 27 cases had been treated by chemotherapy and radiotherapy, two cases had been treated rituximab and three cases were followed without therapy.
Results: Seventy three percent of the cases had early stage disease, B symptoms and bulky disease were seen in in 15 and 6 cases, respectively. Bone marrow involvement was detected in 6 cases. Leukocytosis was found in 14 cases, lymphocytopenia in 11 cases and NLR was >4 in 26 cases. According to the relapse status mean and median progression free survival (PFS) were longer in cases with early stage disease (p:0.101) and with bulky disease (p:0.119). Mean and median PFS were significantly shorter in cases who had B symptom, low serum albumin and hemoglobin, leukocytosis, lymphocytopenia and high NLR(>4) groups (p:0.034, p:0.0001, p:0.033, p:0.0001, p:0.014; respectively). Figure 1 shows PFS curve according to NLR groups. According to multiple Cox regression analyses, among age, hemoglobin, albumin, stage, B symptom and NLR, NLR (OR:3.3; 95%CI:1.2-8.9; p:0.017) and hemoglobin (OR:4.8; 95%CI:1.4-16.7; p:0.050) were found to be independent risk factors related with PFS.

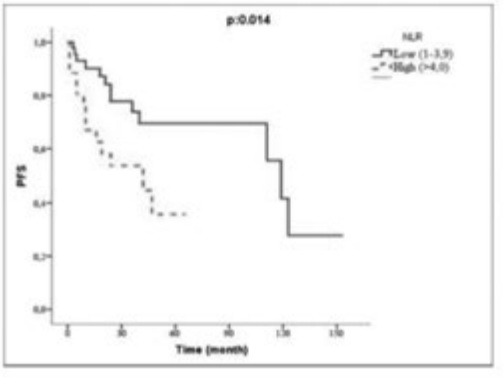

Figure 1.

Summary/Conclusion: Higher NLR (>4) was found to be an important prognostic factor in cases with NLPHL. In relapse setting, developing an alternative scoring system including B symptoms, bulky disease and NLR will be more informative in determination of risk groups and risk adapted treatments in cases with NLPHL. Note: Ethical approval has been taken from Cukurova University

PATIENT CHARACTERISTICS, TREATMENT PATTERNS, AND CLINICAL OUTCOMES IN THE FRONTLINE TREATMENT OF ADVANCED-STAGE CLASSICAL HODGKIN LYMPHOMA IN THE UNITED KINGDOM, FRANCE, AND GERMANY

T. Illidge[1], M. Hentrich[2], A. Stamatoullas-Bastard[3], E. Zagadailov[4], A. Gautam[4], N. Way[5], J. Cambron-Mellott[5], M. Dalal[4,*]

[1]University of Manchester, Christie Hospital, Manchester, United Kingdom, [2]Rotkreuzklinikum Munich, Munich, Germany, [3]Henri Becquerel Center, Rouen, France, [4]Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Ltd, Cambridge, [5]Health Outcomes Practice, Kantar Health, San Mateo, United States

Background: Classical Hodgkin lymphoma (cHL) is a hematologic malignancy with poor prognosis for advanced-stage patients who do not respond well to frontline (FL) therapy.
Aims: This study examines patient characteristics and clinical outcomes associated with FL systemic regimens used to treat advanced-stage cHL in the United Kingdom (UK), France (FRA), and Germany (DE).
Methods: Hematologists and oncologists (N=57) from the UK, FRA, and DE retrospectively identified patients diagnosed with advanced stage cHL and treated with FL systemic therapy: doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD); doxorubicin, vinblastine, and dacarbazine (AVD); dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone (BEACOPP$_{escalated}$); BEACOPP. Descriptive statistics examined patient characteristics, FL regimens, and associated adverse events (AEs). Bivariate analyses (ANOVA, chi-square, or Fisher's exact test) compared patient characteristics by regimen. Univariate analyses and bivariate analyses (chi-square or Fisher's exact test) compared clinical outcomes by regimen. Progression-free survival (PFS) was assessed with Kaplan Meier curves.
Results: Mean (SD) age at initial cHL diagnosis was 46.2 (16.2) for the aggregate sample (N=297), which was mostly male (65.0%), evenly distributed across the UK (32.3%), FRA (34.3%), and DE (33.3%), comprised of patients initially diagnosed with advanced-stage cHL (Stage IIb 19.2%, Stage III 35.1%, Stage IV 45.7%), and patients treated in FL with ABVD (57.6%), AVD (7.1%), BEACOPP (13.1%), or BEACOPP$_{escalated}$ (22.2%). Among patients who received ABVD, AVD, BEACOPP, and BEACOPP$_{escalated}$, administration of FL systemic regimen type differed by patient mean [SD] age at initial cHL diagnosis (50.1 [16.3], 60.5 [10.2], 37.2 [14.2], 36.8 [10.1], respectively), p<.001, and by country (UK 45.0%, FRA 35.1%, DE 19.9%), (UK 52.4%, FRA 9.5%, DE 38.1%), (UK 10.3%, FRA 43.6%, DE 46.2%), (UK 6.1%, FRA 34.9%, DE 59.1%), respectively, p<.001. Among patients who received ABVD, AVD, BEACOPP, and BEACOPP$_{escalated}$, AEs included, but were not limited to alopecia (46.2%, 38.1%, 48.7%, 81.8%, respectively), neutropenia (22.2%, 4.8%, 28.2%, 51.5%, respectively), infection (7.0%, 9.5%, 5.1%, 18.2%, respectively), and peripheral neuropathy (4.1%, 4.8%, 7.7%, 1.5%, respectively). Response at end of FL therapy differed within the aggregate sample (complete response [CR] 66.3%; partial response [PR] 22.2%; stable disease 7.4%; progressive disease 1.4%; "no response" [refractory] 2.7%), p<.001. Responses by FL regimen are presented in **Table 1**. Median follow-up was 8.8 months (range: 0-64 months). Unadjusted 12-month PFS by FL regimen is presented in Table 1.

Table 1.

Table 1. Clinical outcomes by FL systemic regimen

	ABVD (N=171)	AVD (N=21)	BEACOPP (N=99)	BEACOPP$_{escalated}$ (N=66)
Complete Response (CR)	70.8%	38.1%	59.0%	68.2%
Partial Response (PR)	19.3%	23.8%	35.9%	21.2%
Stable Disease	5.3%	28.6%	5.1%	7.6%
Progressive Disease	1.2%	4.8%	0.0%	1.5%
No Response (Refractory)	3.5%	4.8%	0.0%	1.5%
Mean (SD) Patient Age	50.1 (16.3)	60.5 (10.2)	37.2 (14.2)	36.8 (10.1)
Unadjusted 12-Month PFS (95% CI)	67.4% (59.3%- 75.5%)	31.9% (4.3%- 59.6%)	65.8% (48.0%- 83.6%)	53.9% (38.4%- 69.4%)

Note: responses (CR, PR, stable disease, progressive disease, no response [refractory]) were observed and recorded at the end of FL therapy; responses differed by frontline regimen, p=.02. ABVD: doxorubicin, bleomycin, vinblastine, and dacarbazine; AVD: doxorubicin, vinblastine, and dacarbazine; BEACOPP$_{escalated}$: dose-escalated bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone; BEACOPP: bleomycin, etoposide, doxorubicin, cyclophosphamide, vincristine, procarbazine, and prednisone; FL: frontline; PFS: progression-free survival; CI: confidence interval; N: sample size; SD: standard deviation.

Summary/Conclusion: ABVD and AVD were more commonly administered for older patients, whereas BEACOPP and BEACOPP$_{escalated}$ were more commonly administered for younger patients. Alopecia, neutropenia, and infection were most commonly observed in BEACOPP$_{escalated}$ patients, whereas peripheral neuropathy was most commonly observed in BEACOPP patients. CR at end of FL therapy was more common in ABVD and BEACOPP$_{escalated}$ patients than in AVD and BEACOPP patients in this retrospective analysis. These findings demonstrate that treatment outcomes in the real-world practice setting may be different than those observed in clinical trials. These findings underscore the unmet need in patients with cHL and the importance of novel treatments.

PB2000

INTERIM POSITRON EMISSION TOMOGRAPHY AND CHILDHOOD HODGKIN INTERNATIONAL PROGNOSTIC SCORE CAN PREDICT SURVIVAL OF CHILDREN WITH HODGKIN LYMPHOMA IN DEVELOPING COUNTRIES

R. Khedr[1,2,*], S. mahfouz[2], L. Shalaby[3]

[1]Pediatric Oncology, Children's cancer hospital Egypt 57357, [2]Pediatric Oncology, National Cancer Institute, Cairo University, [3]Pediatric Oncology, National Cancer Institute, Cairo, Egypt

Background: Although "interim" positron emission tomography (PET) may inform therapeutic decisions, Risk stratification at diagnosis could may allow earlier and potentially more efficacious treatment modification during treatment of HL.

Aims: In this study we aimed to identify the prognostic role of both the IPET and the CHIPS in predicting the prognosis of HL in our center.
Methods: This is a retrospective, single center study where a total of 140 patients with newly diagnosed Hodgkin lymphoma were enrolled. Only 83 patients were eligible for analysis of both IPET and CHIPS scoring. PET scan was performed at baseline and after two cycles of chemotherapy. Treatment was not changed according to the results of the interim scan. PET scans reports was used using the Deauville five-point scale, blinded to treatment outcome. Childhood Hodgkin International Prognostic Score (CHIPS),was evaluated [included age (<13), number of involved sites (<3), hemoglobin (<10.5), albumin (<3.5), and erythrocyte sedimentation rate (ESR) (<20). ESR<50].Log rank testing was used to compare EFS for each CHIPS (0–3).
Results: Eighty-three scans out of 140 patients were eligible for analysis of both IPET and CHIPS scoring. Twenty six patients were scored positive (31.3%) and 57 (68.7%) as negative. The 5- years overall survival (OS) was 94%, 83% for patients with interim positive scans and 97% for patients with interim negative scans (P<0.01). The 5-year Event-free survival (EFS) rate was 86.7% for the whole study population, 76% for patients with interim positive scans and 91% for patients with interim negative scans (P<0.04). Stage 4 disease, large mediastinal mass, albumin (<3.5), and fever were independent predictors of EFS that were each assigned one point in the CHIPS. 3-year EFS was 95.7% for patients with CHIPS=0, 84.2% for patients with CHIPS=1, 75% for patients with CHIPS=2, and 80% for patients with CHIPS=3 (mostly due to a very limited number of patients) .

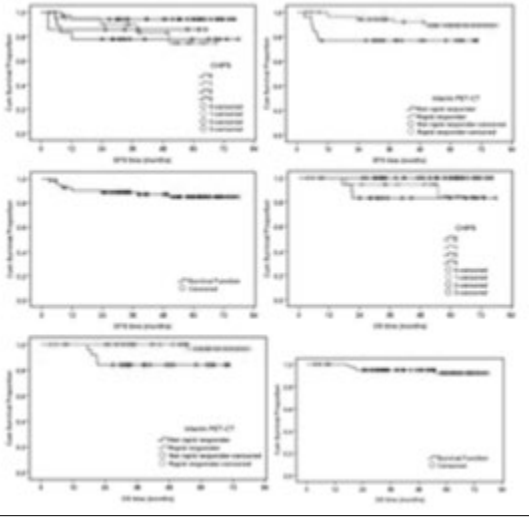

Figure 1.

Summary/Conclusion: The prognostic role and validity of using the interim PET scan response have been confirmed to be strongly related to treatment outcome by the present study. However the use of CHIPS scoring CHIPS is a good inexpensive approach to predicting risk in patients with HL that may improve ability to tailor therapy to risk factors known at diagnosis.

PET-CR +2 METABOLIC RESPONSE GUIDED TREATMENT IN PEDIATRIC HODGKIN LYMPHOMA PATIENTS

V. Papadakis[1,*], K. Antoniadi[1], C. Kelaidi[1], M. Ampatzidou[1], V. Lyra[2], I. Sevaslidou[2], J. Nikas[3], M. Gavra[3], A. Alexopoulou[4], K. Stefanaki[5], S. Polychronopoulou[1]

[1]Pediatric Hematology Oncology, [2]Nuclear Medicine, [3]Computerised and Magnetic Resonance Imaging, Agia Sofia Children's Hospital, [4]Radiation Therapy, P&A Kyriakou Children's Hospital, [5]Pathology, Agia Sofia Children's Hospital, Athens, Greece

Background: The prognostic value of post 2-3 chemotherapy blocks PET-CT scan metabolic response has established validity for adult Hodgkin Lymphoma (HL) patients (pts). The Pediatric Protocol EuroNet-PHL-C1 STUDY evaluates patients with CT/MRI imaging and PET-CT-Scan following 2 OEPA chemotherapy blocks in an effort to avoid irradiation.
Aims: To present preliminary imaging and outcome results of a Greek pediatric pt cohort.
Methods: From 2/2009-4/2017 22 pts (13 boys) with median age of 13,1 years (range 3,9-16,3) with newly-diagnosed HL were treated according to the EuroNet-PHL-C1 STUDY. PET-CT-Scan was performed at diagnosis, following 2 OEPA cycles (PET+2) and at the end of treatment. Three Therapy-Groups (TG) were are defined: TG-1: pts stage IA/B, IIA, without mases ≥200 ml, Erythrocyte Sedimentation Rate (ESR)<30mm/hr; TG-2: pts stage IEA/B, IIEA, IIB, IIIA and pts stage IA/B and IA with≥200 ml masses and/or ESR ≥30mm/hr; TG-3: pts stage IIEB, IIIEA/B, IIIB, IV A/B. Treatment plan: Initially 2 OEPA for all pts; 2 or 4 COPP or COPDAC blocks followed for TG2 and TG3 pts, respectively. Irradiation of the initially involved sites 20-30Gy was prescribed only for pts with inadequate response (MRI/CT and/or PET+2) following 2 OEPA blocks, for all TGs.
Results: A total of 22 pts stage IIA (7), III (4/ 1A) and IV (11/ 9B, 8S, 6E) diagnosed with nodular sclerosis (19) or mixed cellularity (3) were treated according to groups TG1 (3), TG2 (3) and TG3 (16). Seven pts had bulky-disease (stage II:5, stage IV:2) and 15 pts ESR≥30mm/hr (stage II:1, III:4, IV:10). Adequate overall response following 2 OEPA cycles was observed in 2/3, 2/3 and 5/16 pts group TG1, TG2 and TG3, respectively. Good metabolic response (PET+2 with Dauville-score ≤3) was documented in3/3, 3/3 and 10/16 pts, respectively. Irradiation was prescribed to 11/15 pts following appropriate TG chemotherapy (TG1:1, TG3:10), while 4 TG3 pts had disease progression (3) or no complete response following 6 chemotherapy blocks (1).All 4 received protocol-allocated second line treatment, (IEPx2-ABVDx2) and with responsive disease they underwent autologous stem cell transplantation (ASCT) with BEAM cytoreduction, without irradiation in 2/4, due to good response. Of these, only 1 pt relapsed (4,3 from diagnosis) with single pulmonary nodule; she remains in complete remission following surgical resection only, for another 4,6 years. Another 2 pts relapsed 3,8 and 0,7 years from diagnosis and were treated accordingly (IEPx2-ABVDx2 and ASCT), without irradiation.
Summary/Conclusion: PET+2 inadequate metabolic response was observed in pts who had resistant disease or subsequent relapse. To the contrary, it appeared that pts with adequate mass regression and metabolic response can be managed without irradiation, while maintaining CR. Pts with resistant or relapsed disease can be rescued with second line chemotherapy and ASCT. Good response following ASCT allows for elimination of irradiation, too. The effectiveness of intensification of chemotherapy following the initial 2 OEPA cycles, in PET+2 scan positive pts while diminishing the number of pts receiving irradiation in children, is under investigation, in an effort to improve overall outcome, while diminishing the number of pediatric pts receiving irradiation.

PB2002

EFFICACY AND SAFETY OF HIGH DOSE BENDAMUSTINE PLUS BRENTUXIMAB VEDOTIN IN REFRACTORY OR RELAPSED CLASSICAL HODGKIN LYMPHOMA: A SINGLE CENTER EXPERIENCE

M. Raimondo*, R. Della Pepa, C. Giordano, N. Pugliese, C. Cerchione, F. Trastulli, C. Mortaruolo, I. Zacheo, M. Picardi, F. Pane

Hematology, Federico II, University of Naples, Naples, Italy

Background: The management of patients with refractory or relapsed Hodgkin lymphoma (HL) remains controversial. A standard salvage therapy is DHAP chemotherapy treatment (dexamethasone, high-dose cytarabine, cisplatin) followed by autologous stem cells transplant (ASCT) which obtains an ORR of about 50%. Bendamustine has demonstrated efficacy in several lymphoproliferative disorders but limited data are available regarding the schedule in patients with HL, in particular its dosage and possible combinations. Brentuximab Vedotin is a CD30-directed antibody-drug conjugate, currently approved for the treatment of relapsed or refractory HL.
Aims: The objective of this prospective study is to evaluate the efficacy and safety of the salvage cytotoxic regimen with Bendamustine and Brentuximab association in patients with refractory and/or relapsed HL.
Methods: Patients with relapsed or refractory classical HL from September 2013 to November 2017 were enrolled in the prospective study receiving Brentuximab 1.8 mg/kg every 21 days at day 1 associated with Bendamustine 120 mg/mq every 21 days at day 1 and 2 (Bv+B schedule). Dose reductions and/or treatment delay were recorded. The treatment efficacy was evaluated according to the Revised Response Criteria for Malignant Lymphoma. The Overall Response Rate (ORR), Overall Survival (OS) and EFS (Event Free Survival) were analyzed. Any adverse event occurred was recorded and classified for type and grade using NCI-CTCAE criteria (v 4.0).
Results: Twelve consecutive patients (5 M/7 F) with a median age of 32 years (21-44) received this salvage regimen treatment (Bv+B). All patients had an advanced stage disease, with 3 patients having stage IV disease. The median number of prior therapies was 3 (range 2-6) and all patients received ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine) as upfront therapy. All patients received Bv+B schedule as salvage therapy and achieved a complete response (ORR 100%). Ten patients underwent a stem cell trans-

plant (8 autologous and 2 haploidentical), while two patients are currently in follow-up. All patients received primary prophylaxis for chemotherapy related neutropenia with G-CSF. Three patients (25%) had a grade 1 infusion reaction with fever and a skin rash, managed with corticosteroid injections and a successful antihistamine plus corticosteroid prophylaxis in the subsequent cycles of treatment; 4 patients (33%) had a citomegalovirus reactivation treated with Valganciclovir (450 mg twice a day); 2 patients had a grade 1 peripheral neuropathy. A dose reduction of 20% for bendamustine and 10% of brentuximab vedotin was required for 4 patients (33%). No patient had to delay chemotherapy treatment and all patients respected the treatment time schedule. EFS was 90% at 24 months, for a median follow up of 12 months, as one patient did not maintain the complete response and received subsequent salvage treatment. OS was 100%.

*Stage III, multiple lymph node groups on both sides of diaphragm; stage IV, multiple extranodal sites or lymph nodes and extranodal disease.
†seven factors were included: Serum albumin concentration <4 g/dL, hemoglobin concentration <10.5 g/dL, Male sex, age older than 45 years, Ann Arbor stage IV, white cell count > 15.000/µL, lymphocyte count <8% and/or absolute lymphocyte count <600 cells/ µL. Each factor gets 1 point and possible scores range from 0 to 7. A higher score indicates poorer prognosis.
‡ABVD (doxorubicin, bleomycin, vinblastine and dacarbazine), IGEV (Ifosfamide, gemcitabine, vinorelbine), DHAP(dexamethasone, high-dose cytarabine, cisplatin), BEACOPP (bleomycin, etoposide, adriamycin, procarbazine, prednisone, vincristine, cyclophosfamide);
‡RC (Remission Complete); PR (Partial Response); PD (Progressive Disease); SD (Stable Disease)

Summary/Conclusion: High-dose bendamustine plus brentuximab have shown relevant efficacy and a relatively good safety profile in a setting of heavily pretreated patients with HL. Adequate monitoring of CMV reactivation is recommended. This combination could be considered as a bridge to first or second autologous or allogenic SCT. However, these results should be validated by controlled and prospective studies involving larger number of patients.

PB2003

ABSOLUTE LYMPHOCYTE COUNT AND LYMPHOCYTE-MONOCYTE RELATIONSHIP AS A PROGNOSTIC CRITERIA IN HODGKIN'S LYMPHOMA

A. Rukavitcyn[1,*], O. Rukavitcyn[2]

[1]Hematology, [2]Gospitalnaya ploshad' III, Main Military Hospital, Moscow, Russian Federation

Background: Decline the absolute lymphocyte count in the peripheral blood of less than 8% for Hodgkin's lymphoma is an unfavorable prognostic factor, but with the development of induction chemotherapy, it lost significance in the revised IPS-3 scale. To determine the clinical significance of the absolute lymphocyte count, lymphocyte value and the ratio with monocyte we correlated this with present clinical and laboratory features and Progressive-free survival (PFS) after treatment by ABVD (adriamicyn, bleomicyn, vinblastine, dacarbazine).
Aims: Determine the clinical significance of the absolute lymphocyte count, and the ratio lymphocyte with monocyte's to the progression-free survival of patients with Hodgkin's lymphoma treated with the ABVD, according to the other prognostic criteria
Methods: The study included 124 untreated patients with classic Hodgkin's lymphoma from 2002 to 2016, and a median of 29.6 years of age. Inclusion criteria were: a histologically confirmed diagnosis of classical Hodgkin's lymphoma, the time from the onset of the first symptoms of the disease before the start of therapy was 1-2 months. The hemogram examinations till 1-2 days prior to chemotherapy, lymphocyte-monocyte ratio (LMR) was determined by dividing the absolute lymphocyte count on the absolute monocyte count. The minimum duration of follow-up after the last cycle of chemotherapy was not less than 36 months.
Results: In the population of patients (n=124), 74% (n=92) patients achieved and maintained a remission status within 36 months-favorable group. 26% (n=32) of patients did not achieve remission after induction chemotherapy or developed a relapse within 36 months-unfavorable group. In an unfavorable group, 21 patients (64%) had an LMR level less than 2, while in a favorable group in 14 patients (20%) the LMR level was below 2 and 76 patients (80%) had LMR levels in the range 2-5. The disease-free survival (DFS) during 3 years in patients with 3-4 and 4-5 LMR was 92% and only 35% and 61% in groups with LMI<1 and 1-2 respectively (p=0.038 log rank test). Using the ROC curve, the LMR-1.8 threshold level was determined which had the maximum effect on disease-free survival. With 74% specificity and 54% sensitivity, the ROC curve area was 0.73. Multivariate analysis using the Cox proportional hazard model with the inclusion of decrees level of LMR<2, age 45 and older, B-symptoms, IV stage, anemia, decreased serum albumin, increased LDH, leukocytosis, lymphocytopenia revealed that the decreased of level LMR<2 was an independent factor of poor prognosis (p=0.028; RR=1,8, CI=0.4-5.2).
Summary/Conclusion: The decreased of level lymphocyte-monocyte ratio (LMR)<2 can be an independent prognostic factor of patients with classic lymphoma Hodgkin's

PB2004

HODGKIN LYMPHOMA IN ADOLESCENTS TREATED WITH ABVD

B. Sidi Mohamed El Amine*, H. Asma, O. Fouzia, S.A. Nadjet, C. Malika, Z. Naima, Z. Zahia

Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Hodgkin lymphoma (HL) is a most common malignancy affecting adolescents and young adults, but the standard treatment of adolescent patients is not well defined, particularly in the choice between pediatric and adult protocols.
Aims: To compare risk factors and therapeutic outcomes of adolescents and young adults with HL treated with ABVD.
Methods: 98 patient patients treated in our department between 1994 and 2010 were analyzed: 33 adolescents between 15 and 21 years old, and 65 young adults between 22 and 39 years. All patients received as initial chemotherapy the ABVD protocol, followed in 65 (66.3%) by radiotherapy. We compared the patient characteristics of the two populations using Fisher's exact test. Survival was estimated using the Kaplan and Meier method, and compared by the log rank test. Cox proportional hazard regression was used to evaluate prognostic factors in adolescent patients.
Results: Histological type 2 and hypoalbuminemia were more frequent in adolescent patients (P=0.05, P=0.02 respectively). The incidence of other risk factors were without significant difference between the two populations. With a median follow-up of 67 months, overall survival (OS) and event-free survival (EFS) at 5 years were in the order of 79% and 72% for all patients. The overall rate of complete remission (CR) was 87.8% : 84.8% in adolescents and 89% in young adults (P=0.53). The log rank test showed no significant difference between the two age groups, in terms of overall survival (P=0.31) or EFS (P=0.51). At 5 years, the estimate of OS and EFS are in the order of 77% and 74% for young adults, 73% and 68% for adolescents, respectively. After cox regression analysis, two factors were crucial for the survival of adolescent patients: the presence of bulky disease (P=0.008) or an extranodal lymphoma involvement (P=0.04).
Summary/Conclusion: The prognosis and risk factors of adolescent patients and young adults with HL treated with ABVD are similar. These data suggest that adult protocols can offer a safe and effective treatment option for adolescent patients.

PB2005

LONG-TERM ENDOCRINOLOGIC SIDE EFFECTS OF CHILDHOOD HODGKIN'S LYMPHOMA TREATMENT

G. Aydogan*, M. Eltan, F. Akici, Z. Salcioglu, D. Tugcu, N. Aktay

Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Childhood Hodgkin's lymphoma has been treated successfully

for decades now. Long-term survivors of Hodgkin lymphoma (HL) are at an increased risk for a range of late complications. Raising awareness, close follow-up, and adoption of selected early-detection and risk-reduction strategies may help to reduce the adverse impact of these late effects on patients.
Aims: The aim of this study is the evaulation of long-term endocrinologic side effects on thyroid functions and bone mineral density due to childhood Hodgkin's lymphoma treatment.
Methods: This prospective study was held with 40 patients (34 male, 6 female), who had been treated between 1994-2013 in Pediatric Hematology and Oncology Department of Kanuni Sultan Suleyman Education and Research Hospital. Demographics, histopathological characteristics of tumor, stage, age at the time of radiotherapy, dose of radiations, time period after radiotherapy protocol, TSH, free T4, antithyroglobulin, anti-thyroid peroxidase, calcitonin, thyroglobulin, thyroid ultrasonography, any thyroid nodules, levels of calcium, phosphate, magnesium, ALP, 25OH-vitamine D, PTH and z-scores were all recorded for each patient on a study form. Whenever a nodule was detected in thyroid ultrasonography, sintigraphy was carried out followed by a biopsy, if indicated.
Results: The ages of patients were ranging between 4-31 years (mean 14.13±6.08). All patients were treated with chemotherapy combined with radiotherapy. Average dose of radiotherapy was 21.487± 4.487 Gy. In 72.5% of patients the primary disease was localised on head and neck. Seven patients had B symptoms. Eleveted TSH levels were detected in twelve of forty patients (30%). Thyroid hormon therapy was given to five patients, who have clinical symptoms of hypothyroidism. Nodule in thyroid gland was detected in five patients by ultrasonography. Three patients were directed to biopsy according to scintigraphic and ultrasonographic evaluations. Hypothyroidism was detected 3.10±2.02 years and nodules were detected 8.90±7.90 years after treatment. Five (12.5%) out of 40 patients had osteoporosis detected by dual-energy X-ray absorbsiometry. Mean age of patients with osteoporosis was 16.4±6.88 while mean age of patients was 13.8±6. In 25 patients 25-OH D vitamin levelswere below normal. Among 7 patients having B symptoms 3 (42.8%), 11 patients under combined chemotherapy with steroid 3 (27.5%) had osteoporosis.
Summary/Conclusion: Patients with Hodgkin lymphoma under treatment may have abnormal thyroid functions and osteoprorsis as long term complications. Their evaluation for thyroid functions and osteoporosis are needed. Timely replacement therapies diminish the appearance of these complications and improve the quality of life of the patients.

MULTICENTRE STUDY OF QUANTITATIVE PET VALUES IN PRIMARY PATIENTS WITH HODGKIN LYMPHOMA (HL): UPDATE RESULTS

I. Kriachok[1,*], O. Novosad[1], I. Pastushenko[1], T. Skrypets[1], T. Kadnikova[1], I. Tytorenko[1], K. Ulianchenko[1], O. Gorbach[1], V. Kozlov[2], L. Mykhalska[3], V. Kosinova[4], N. Kostiukova[5], O. Karnabeda[6], V. Stratienko[7], M. Novikov[4], O. Oliinichenko[8], I. Kmetyuk[9], O. Karpova[10], A. Ashykhmin[11], O. Lukjanec[12]

[1]Oncohematology, National Cancer Institute, Kiev, [2]Department of Internal Medicine #[1] with additional course of cardiovascular diseases, National Medical University, Odessa, [3]Center of Hematology, Clinical Hospital "Feofaniya", Kiev, [4]Oncology Hospital "LISOD", [5]Kyiv centre of bone marrow transplatation, [6]Oncology Hospital "Innovacia", Kyiv, [7]Regional Clinical Hospital, Kherson, [8]Center of Nuclear Medicine KMCOC, [9]Clinical Hospital «Feofaniya", [10]Clinical Hospital «Feofaniya, [11]Radiology, National Cancer Institute, Kyiv, [12]Cherkassy Regional Oncology Center, Cherkasy, Ukraine

Background: PET, combined with computed tomography (PET-CT), performed during and after therapy, has a high prognostic value for predicting first-line therapy results in Hodgkin lymphoma (HL) patients. Quantitative PET parameters (qPET) as a predictive factor for HL progression are still not well established.
Aims: The primary endpoint was to evaluate influence qPET values of event-free survival (EFS) after treatment. We analyzed absolute value of PET parameters, such as negative predictive value (negative PET scan and no treatment failure, NPV), positive predictive value (positive PET scan and treatment failure, PPV) and qPET (SUVmean, SUVmax, MTV and TLG) which might associate with EFS.
Methods: Quantitative PET parameters at the baseline (PET-1), interim (PET-2, after 2-4 cycles) and end of chemotreatment (PET-3) PET-CT scans were investigated. Metabolic PET-CT imaging were performed at participating PET centers according to routine protocols, compatible with EANM guidelines for FDG PET-CT imaging in malignant tumors. MTV was computed by using the 41% maximum standardized uptake value thresholding method, and the optimal cutoff for survival prediction was determined.
Results: In this retrospective analysis 96 patients with HL with a stage I-II (58.3%), III-IV (41.7%) who were admitted between Aug 2012 and Feb 2018 in 9 Ukrainian hematological centers were analyzed. Patients were treated with ABVD or BEACOPP-14/esc, based on risk group. The ORR of 96 patients (CR ,PR) was 85.4%. A negative PET-2 had 76% pts, while 9.4% had a positive PET-2. Patients with negative PET-2 and positive PET-2 had CR rates of 75% and 4.16%, respectively, which yielded a PPV of 11.4% and NPV of 88.6%. ROC analysis revealed that PPV is an important marker which is associated with poor EFS in primary patients with HL (Se=100%; Sp=100%; AUC=1.0, p<0.0001). 5-year EFS was 100% for NPV patients and 10% for PPV patients, which was statistically different (p<0.05). Multivariate analysis confirmed NPV and PPV significant variables on EFS (p<0.0001). In our study we found two new strong associations between qPET at PET-3 and EFS (PET-3 negative in 77% cases): SUVmax [Se=63%; Sp=100%; AUC=0.88, *p*<0.0001], SUVmean [Se=75%; Sp=90%; AUC=0.86, *p*<0.0001] at PET-3 and EFS by ROC analysis. Patients with SUVmax<1.84 had higher level of 5-year EFS *vs* SUVmax >1.84 (93% *vs* 15%, p<0.05). Also, 5-year EFS was 85% *vs* 25% in patients with SUVmean<3.19 *vs* SUVmean >3.19, respectively (p<0.05). ∑MTV [HRs1.4; 95% (CI) 1.0–2.0, *p*<0.0001 by Cox regression] and TLG [Se=75%; Sp=100%; AUC=0.97, *p*<0.0001 by ROC analyses] parameters at PET-3 were confirmed as important markers to predict survival in patients with primary HL. 5-year EFS was 85% and 20% in patients with ∑MTV<0 and ∑MTV >0, respectively (*p*<0.05). Unfortunately, qPET at PET-1 and PET-2 were not statistically significant in predicting clinical outcomes, due to the small sample size of our study.
Summary/Conclusion: Quantitative PET parameters is an important tool for clinicians in the diagnosis and management of patients with HL. The prognostic role and validity of the qPET for interpretation of PET should be confirmed prospectively.

PB2007

ANTI-PD1 INHIBITOR FOLLOWED BY ALLO STEM CELL TRANSPLANTATION IN 6 HEAVELY PRETREATED LYMPHOMA'S PATIENTS: EXPERIENCE OF JULES BORDET INSTITUTE

A. Salaroli*, P. Lewalle, S. Wittnebel, M. Maerevoet

Hematologie, Institut Jules Bordet, Brussels, Belgium

Background: Anti–programmed cell death protein 1 (PD-1) antibodies are tested in patients (pts) with advanced lymphoma. Following treatment, many of those ps are likely to be candidates for allogeneic hematopoietic stem cell transplant (HSCT). Armand and Merryman demonstrated that PD-1 blockade in relapsed Hodgkin-lymphoma (cHL) followed by allo-HSCT appears to be highly efficacious but frequently complicated (22-44%) by rapid onset of severe and treatment-severe and treatment-refractory graft *versus* host disease (GVHD). One-year overall and progression-free survival rates were 89%.
Aims: We report here the Institut Jules Bordet's experience of 5 pts, 3 Hodgkin lymphoma (cHL) and 2 primary mediastinal B cell lymphoma (PMBCL) and which achieved a complete remission (CR) after antiPD1 inhibitor and or chemotherapy consolidated with allo-HSCT. All of these patients have been heavily pretreated. A sixth pt is just admitted for this procedure.
Methods: Table 1. Pts characteristics and outcome. The data incuded the data from the sixth pt just admitted will be detailled and uptdated.
Results: The time from the last Nivolumab from allo-HSCT is of 25 to 70 days. One pt died 21 days after allo-HSCT of RSV lung infection and septicemia. This patient has been treated by radiotherapy in the lung and gemcitabine few months before HSCT and that could be explained the pulmonary failure. All pts have viral and bacterial infectious complications, mainly grade I-III in severity, Two pts developed a grade II acute and one of them pts a chronic cutaneous GVHD, managed by corticoid alone.
Summary/Conclusion: AntiPD1 therapy could be represent a new opportunity to achieve a complete remission and bridge to an Allo-HSCT and may be cure heavely pretreated cHL and PMBCL pts. In our experience, all pts have presented viral and bacterial infections, mainly grade I-III in severity, as expected for these population. Two pts have a GVHD resolved with systemic and local corticoid .Four of these 5 patients are still alive and in complete remission respectively at 21, 175, 280 and 336 days after Allo-HSCT. A sixth pt is still ongoing for Haplo-ASCT

PB2008

PREGNANCY RATE AND RISK OF RELAPSE IN PATIENTS IN COMPLETE REMISSION AFTER HODGKIN'S LYMPHOMA

F. Gaudio[1,*], C. Nardelli[2], T. Perrone[1], F.E. Laddaga[3], S. Paola[1], M.L. di Noi[1], S. Mallano[1], R. De Palo[2], G. Specchia[1]

[1]Department of Emergency and Organ Transplantation (D.E.T.O.), Hematology Section, [2]Unit of Pathophysiology of Human Reproduction and Gametes

Cryopreservation, [3]Pathology, Bari, Italy

Background: As the number of survivors of young female Hodgkin's lymphoma (HL) increases, it is becoming more common to manage the pregnancies of women who have a history of exposure to chemotherapies and radiation therapy. Little is known about the success rate of women attempting pregnancy. Many patients and clinicians are worried that pregnancy after the diagnosis of HL may increase the risk of relapse, despite a lack of empirical evidence to support such concerns
Aims: In the present study we included 61 women who received a diagnosis of HL between 2007 and 2014 and who were younger than 40 years of age and were in complete remission and alive without relapse >or=3 years after treatment.
Methods: Of these patients, 45 (74%) patients had had stage I-II, 16 (26%) patients stage III-IV; 18 (30%) patients suffered from constitutional symptoms; 35 patients (57%) had bulky disease and 12 (20%) had extranodal involvement. Before treatment, 58 (95%) patients reported a regular menstrual cycle. We determined the pregnancy rate, and time-to-pregnancy among survivors who had become pregnant, or tried to become pregnant for over 2 months following chemotherapy.
Results: Among the 61 women with HL, 29 (48%) were nulliparous throughout follow-up, 25 (41%) were parous but had no pregnancies during follow-up, and 7 (11%) had a pregnancy during follow-up. After a median follow-up of 5 years, 11 (18%) women had reached menopause before the age of 40 years (range: 19-39 years; median: 33.5 years). A regular menstrual cycle was reported by more than 90% of female survivors of early-stage HL (recovery time mostly 12 months). Ten tried to become pregnant; 3 without success; 7 women became pregnant with the birth of 6 healthy children. The median time-to-pregnancy among HL survivors was 2.0 months. The 12-month pregnancy rate was 70%. The median time from the end of the therapy to pregnancy was 40 months. No recurrence occurred. In one case, 3 months after the birth of the child acute myeloid leukemia occurred, and the patient died.
Summary/Conclusion: We found no evidence of significant impairment of the fertility of female HL long term survivors We found no evidence that a pregnancy after diagnosis increases the relapse rate among women whose HL is in remission. Survivors of HL need to consider a range of factors when deciding about future reproduction.

PB2009

TREATMENT OUTCOMES FOR HODGKIN LYMPHOMA WITH BULKY MEDIASTINAL DISEASE (2BX): HOSPITAL AMPANG'S EXPERIENCE

S. Hon*, T.S. Leong, S.M. Tan, P.K. Liew, T.C. Ong, J. Sathar, J. Tsen Chuen Tan

Haematology Unit, Hospital Ampang, Selangor, Malaysia

Background: Hodgkin Lymphoma (HL) with bulky mediastinal disease represents a unique cohort of patients which pose specific challenges in diagnosis, treatment, and prognosis.
Aims: We aim to analyse the treatment outcome of these patients in Hospital Ampang.
Methods: This is a retrospective analytical study. Data was obtained from Hospital Ampang electronic database. Recruitment started from January 2006 and December 2015.
Results: A total of 77 adult patients with HL with bulky mediastinal disease were identified. All patients were followed up from January 2006 till December 2017. The median age of diagnosis was 25 years (range 14 to 61 years), and 56% (n=43) were males. 47% (n=36) are of nodular sclerosing (NS) subtype. 95% (n=73) were treated with standard protocol, ABVD, whereas 5% (n=4) were treated with BEACOPP protocol. 51% (n=39) of them have received upfront consolidative radiotherapy. The median follow-up duration was 54 months (range 1 to 137 months). 42% (n= 32) attained complete remission whereas 30% (n= 23) had progression of disease in all patients treated with chemotherapy. Overall survival (OS) rate was 88.9% at 48 months and 83.7% at 60 months in all patients treated with chemotherapy. Progression free survival (PFS) was 75.1% at 24 months and 61.7% at 48 months. Amongst the ABVD cohort, the relapse rate was 23% (n=17), 45% (n=33) needed salvage chemotherapy and 25% (n=18) underwent stem cell transplantation. Among the patients who underwent salvage chemotherapy, 39% (n=13) eventually passed on. Amongst the transplanted patients, the mortality rate was 27% (n=5) due of progression of disease.
Summary/Conclusion: Bulky mediastinal HL is a peculiar condition with the outcome determined by the primary treatment. From our cohort, 45% of patients undergoing conventional therapy with ABVD require salvage chemotherapy. This suggest that more intensive chemotherapy should be employed as an initial treatment for better tumour load control and downgrade accordingly based on the interim PET-CT report.

PB2010

PROGNOSTIC FACTORS OF SURVIVAL IN ADOLESCENT AND YOUNG ADULT (AYA) PATIENTS WITH EARLY-STAGE CLASSICAL HODGKIN LYMPHOMA ACCORDING TO SUBTYPE: A 15-YEAR STUDY IN A PERUVIAN SINGLE CANCER CENTER

J. Vasquez*, J. Moreno, J. Bravo, L. Mas, H. Gomez

Medical Oncology, Instituto Nacional de enfermedades neoplásicas, Lima, Peru

Background: Hodgkin lymphoma is a good prognostic hematological malignancy, early disease has been evaluated in population regardless age, however prognostic factors were not evaluated in adolescents and young adults according to subtype.
Aims: To describe prognostic factors for progression-free survival and overall survival according histologic subtype in AYA population.
Methods: Retrospectively, we reviewed medical records from epidemiology department of Peruvian National Cancer Institute for all classical Hodgkin lymphoma patients aged between 15 and 39. Patients were treated from 2000 to 2014 and received at least 2 cycles of chemotherapy. Survival curves were estimated by Kaplan Meier, the difference was performed by the log-rank test, Cox proportional hazard models were used to identify prognostic factors of survival. Statistical analysis was based on IBM SPSS software version 24.

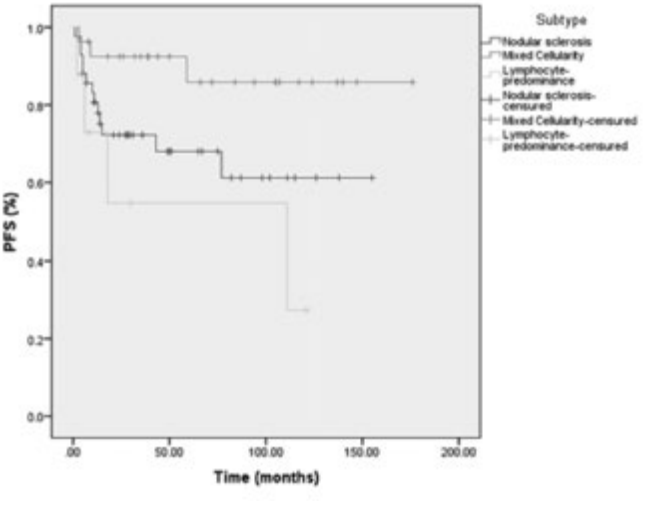

Figure 1.

Results: 1037 patients were admitted in the study period, 387 were AYAs, 77 (19.8%) m*et al.*l criteria. Median age was 25 years (15-39). 39 (50.6%) were male. Nodular sclerosis was the most common subtype with 42 (54.5%) followed by mixed cellularity with 27 (35.1%) and lymphocyte-predominance with 8 (10.4%). According to stages, II stage was more frequent with 69 (89.6%), B symptoms was present in 33 (40.3%). The primary site more common was cervical lymph node with 49 (63.65%). Erythrocyte sedimentation rate (ESR) of 1-30 was seen in 17 patients, 31-50 in 7 patients and 51 or more in 16 patients. Extra lymph node was present in 5 patients, lymph node involvement >2 in 41, bulky disease was present in 8 primary mediastinal lymphomas and in the same number for cervical lymphadenopathy. Regarding the treatment all patients received ABVD chemotherapy with a median of 6 cycles. 56 patients (72.7%) patients received radiotherapy subsequently to chemotherapy. 49 patients (63.6%) achieved complete response, 24 (31.2%) had partial response, 4 (5.2%) had progressive disease. The median progression-free survival was not reached, five-year PFS was 73.3%, univariable analysis (UA) showed statistical significance (p=0.02) for histologic subtype and not achieving a complete response with p<0.01. In the bivariable analysis (BA) the only poor prognostic factor was not achieving a complete response (Hazar ratio (HR) =4.76, 95% confidence interval (CI)=2.87-7.91, p=<0.01). The median overall survival (OS) was not reached, five-year OS was 95.7%. In the UA not achieve a complete response was the only poor prognostic factor with p=<0.01.
Summary/Conclusion: Classic Hodgkin lymphoma in early stage has a long-term overall survival. Radiotherapy do not impact neither OS nor PFS. Histologic subtype is a poor prognostic factor for PFS in UA but not in BA. The only poor prognostic factor for both PFS and for OS was not achieving a complete response.

PB2011

EXPRESSION OF CD20 DOES NOT IMPACT OUTCOME IN CLASSICAL HODGKIN LYMPHOMA IN THE CONTEMPORARY ERA OF THERAPY

R.A. Alshammari*, M. Snnallah, B. Alahmari, A. Alhejazi, A. Al Askar, M. Alzahrani, M. Damlaj

King Abdulaziz Medical City, Riyadh, Saudi Arabia, Riyadh, Saudi Arabia

Background: Prevalence of cluster of differentiation 20 (CD20) in classical Hodgkin Lymphoma (cHL) has been reported to range from 10-20%. However, the prognostic impact of such expression has been variable in the literature. Earlier reports indicated improved progression free survival (PFS) and overall survival (OS) (Tzankov *et al*., 2003) but such findings were later refuted where it was found to confer an adverse outcome (Portlock *et al*., 2004).
Aims: The primary aim of this project is to retrospectively study the prevelance of expression of CD20 in Hodgkin Lymphoma, its prognostic impact on response and overall outcome and to ascertain the role of Rituximab in managing such cases. The aim of this study is to examine the prevalence and prognostic impact of CD20 expression in cHL in a patient population from the Middle East and North Africa Region (MENA).
Methods: After due IRB approval, patients diagnosed with cHL who received frontline therapy at our institution from 2008-2016 were identified and included for further analysis. All variables were retrospectively extracted. CD20 expression of 10% or higher was considered positive. Patients with nodular lymphocyte predominant HL were excluded. Cohorts were stratified per expression of CD20 and compared using Chi-squared and Wilcoxon tests, as appropriate. PFS was defined as time from diagnosis until progression or death due to any cause. Time to end point analysis was performed with the method of Kaplan and Meier with log ranks. Statistical analysis was computed using JMP software.
Results: A total of 199 patients were identified and included for further analysis. Prevalence of CD20 expression was noted in 41 (20.6%) of patients. The cohort was subsequently stratified per CD20 expression. Baseline age, stage, chemotherapy and radiotherapy delivered was similar between the strata. The monoclonal antibody Rituximab was used more frequently in those with CD20 expression (34% *vs* 0.6%; p<0.0001). There was also a trend of significance for higher proportion of male gender in the CD20 expressing cohort (34% *vs* 0.6%; p<0.0001). The estimated 2 year PFS was 71.2% *vs* 69.5% for CD20 positive and negative, respectively (p=0.52). The estimated 2 year OS for those with or without CD20 expression was 87.4% and 90.8%, respectively (p=0.96).

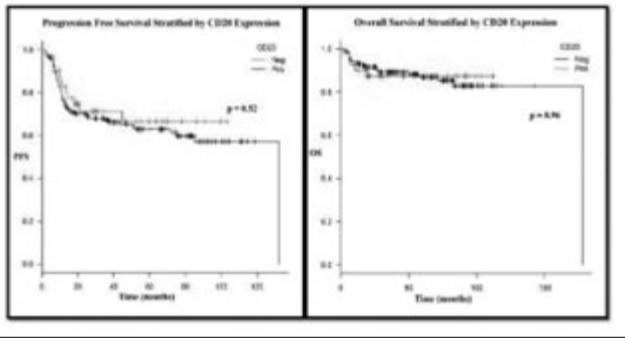

Figure 1.

Summary/Conclusion: We observed a comparable prevalence of CD20 expression in patients from the MENA region with cHL. However, in contrary to reported literature, CD20 expression did not confer an altered prognosis. It is possible that such expression is rendered insignificant in the contemporary era of therapy.

PB2012

CLASSICAL HODGKIN LYMPHOMA TREATMENT PATTERNS, MOLECULAR PROFILING, AND CLINICAL OUTCOMES IN US ONCOLOGY PRACTICES: A PROSPECTIVE OBSERVATIONAL STUDY

C. Yasenchak[1,*], P. Armand[2], S. Larson[3], D. Stevens[4], T.K. Le[5], F. De Solda[5], S. Samakoglu[5], S. Gajavelli[5], J. Svoboda[6]

[1]Willamette Valley Cancer Institute and Research Center/US Oncology Research, Eugene, [2]Dana-Farber Cancer Institute, Boston, [3]University of California, Los Angeles, Los Angeles, [4]Norton Cancer Institute, Louisville, [5]Bristol-Myers Squibb, Princeton, [6]University of Pennsylvania, Philadelphia, United States

Background: Newly diagnosed classical Hodgkin lymphoma (cHL) is highly curable with multi-agent chemotherapy (CTx) +/- radiotherapy. However, standard-of-care treatment (Tx) for relapsed/refractory (R/R) cHL fails in ~50% of patients (pts). Recent clinical trials utilizing novel agents, including the PD-1 inhibitors nivolumab and pembrolizumab and the antibody–drug conjugate brentuximab vedotin (BV), have shown efficacy in R/R cHL. However, real-world clinical practice data describing effictiveness, safety, and pt experiences are limited. Better understanding of tumor biology and pt factors may impact Tx choices in cHL.
Aims: To describe current Tx patterns, evaluate clinical and pt-reported outcomes (PROs), and characterize tumor/pt molecular profiles in cHL pts.
Methods: This is an ongoing, observational, multicenter, prospective study (NCT02856646) involving ~80 US oncology practices with a target enrollment of 500 pts and a planned follow-up of ≤5 y. Eligible pts were ≥18 y with histologically confirmed cHL. At enrollment, pts were Tx naïve or within 2 wk of beginning any line of anticancer therapy. Informed consent was obtained for all pts. Index therapy was defined as therapy received at or within 2 wk of enrollment. Data were collected from existing medical records, by pt interaction using PRO questionnaires (FACT-Lym assessment), and by physician assessment. PRO data were collected every 3 mo during the 1st y of enrollment and every 6 mo thereafter. Blood and tissue samples were collected for biomarker analysis.

Table 1.

Demographic and baseline cHL characteristics

Characteristic	All patients (N=116)
Age, median (range), years	39 (18–74)
Male	68 (59)
Disease stage at initial diagnosis	
I	7 (6)
II	53 (46)
III	32 (28)
IV	19 (16)
cHL risk class	
Early favorable	34 (29)
Early unfavorable	12 (10)
Advanced favorable	18 (16)
Advanced unfavorable	17 (15)
International Prognostic Score	
Albumin <4 g/dL	50 (43)
Hemoglobin <10.5 g/dL	15 (13)
Male	68 (59)
Age ≥45 y	43 (37)
Stage IV disease	19 (16)
Leukocytosis	10 (9)
Lymphocytopenia	7 (6)
ECOG status evaluable at study entry	105 (91)
0	42 (40)
1	50 (48)
≥2	10 (10)
≥1 prior systemic therapies	28 (24)
ABVD	25 (89)
BV	7 (25)
ICE	7 (25)

Data reported as n (%) unless specified otherwise. Unknown or missing data are not presented; therefore, percentages in each category may not sum to 100%
ECOG, Eastern Cooperative Oncology Group

Results: At data cut-off (Sept 2017), 116 pts were enrolled; 59% were male, median (range) age was 39 (18–74) y, and 46% had stage II disease at initial diagnosis (**Table**). At enrollment, 76% were Tx naïve and 24% had received prior therapy; index therapies were immunotherapy (3%) and CTx (94%). The most common index CTx were doxorubicin, bleomycin, vinblastine, and dacarbazine (ABVD; 73%); ifosfamide, carboplatin, and etoposide (ICE; 9%); and BV (9%). In total, 78%, 8%, and 3% of index therapies were induction, consolidation/intensification, and maintenance regimens, respectively. Complete response was achieved in 73% of pts who had completed index therapy. Of pts who discontinued index therapy, 33% and 17% discontinued due to relapse/progression and toxicity, respectively. Among pts with Tx-related adverse events (TRAEs), the most common were nausea (41%), fatigue (34%), neutropenia (31%), and constipation (25%). The most common concomitant medications received for TRAEs were ondansetron, filgrastim, and levofloxacin. At baseline, FACT-Lym v4 well-being assessments were available for 115 (99%) pts, (mean) scores were: physical (13.2), social (25.2), emotional (13.3), functional (19.8) and other concerns (25.9). Further PRO analyses will focus on differences between pt groups, stratifying by line of Tx and clinical characteristics over time. Biomarker analyses (9p24.1 amplification, PD-L1 and CD68 expression, Epstein-Barr virus status) for current pts are in process.
Summary/Conclusion: Initial data from the largest prospective observational study in cHL to date suggest that most pts receive multi-agent CTx as 1st-line Tx, consistent with the current Tx paradigm. Effectiveness, safety, and PRO analyses by pt subgroup and Tx line will continue as more pts are

enrolled to identify any tumor biomarkers and pt factors which may correlate with clinical outcomes. Pt recruitment is ongoing.
Study support: BMS.

RISK FACTORS FOR SECOND MALIGNANCES IN HODGKIN LYMPHOMA TREATED WITH ABVD: A SINGLE CENTER EXPERIENCE

I. Herraez[1,*], R. Del Campo[1], A. Cladera[1], M. Mascaró[1], J.M. Guerra[1], D. Gómez[1], E. Gónzalez[1], N. Amer[1], J.B. Borrás[1], A. Gutierrez[2], S. Franco[1], J. Bargay[1]

[1]Hematology, Hospital Son Llatzer, [2]Hematology, Hospital Universitario Son Espases, Palma de Mallorca, Spain

Background: Hodgkin lymphoma (HL) is a lymphoproliferative malignancy that represents approximately 10% of all cases of lymphoma. More than 90% of patients with favorable disease and 70-80% of patients with unfavorable disease are cured with an initial therapy that consists, above all, in two to four cicles of Doxorubicin, Bleomicin, Vinblastine and Dacarbazine (ABVD) for favorable disease or four to six cycles of ABVD for unfavorable disease, with or without radiotherapy. Late therapy-related effects in HL survivors include hypothyroidism, fertility issues, secondary cancers and vascular disease. Second malignancy was first recognized as a problem in the early 1970s. Increasing attention has focused on the more common individual tumor types, including lung cancer and breast cancer. The risk of secondary breast cancers is associated with young age in woman (particularly<30 years) and young age at the time of radiation. In the other hand, it is described that lung cancer risk is increased in who received mediastinal radiation and particularly in smokers.
Aims: We aim to evaluate the risk factors that increase the incidence of secondary malignances in patients con HL treated with ABVD +/- radiotherapy.
Methods: We retrospectively selected from the pathology registries of Son Llatzer Hospital (HSLL) patients with HL treated with ABVD +/- RT. Kaplan–Meier was used for time-to-event variables and the log-rank test was used to compare groups as well as Cox Regression for multivariate survival analysis.

Table 1.

	Incidence of 2nd malignacy	p
Age: <14-65 >65	1 (2%) 9 (19%)	0.001
Sex: -Male -Female	7 (15%) 3 (6%)	0.51
B symptoms: <no <sp	6 (14%) 4 (9%)	0.9
Bulky: <no <sp	0 (0%) 10 (13%)	0.99
ECOG: <0-1 <2-4	7 (9%) 3 (15%)	0.12
Smoker: <no <no	2 (4%) 8 (18%)	0.019
IPS3: <0-3 >3	3 (5%) 6 (17%)	0.002
Albumin: <normal <low	2 (6%) 7 (18%)	0.29
Lymphocytes (/mm3 or %): <0-1000 >1010	7 (26%) 3 (5%)	0.008
BT: <no <sp	1 (5%) 9 (12%)	0.68
Hemoglobin (g/dl): >10.5 <10.5	4 (6%) 6 (19%)	0.01
AA stage: <II III-IV	1 (2%) 9 (17%)	0.039
Number of treatments: <1 <More than 1	9 (11%) 1 (10%)	1

Table 1

Results: From 2001 to 2017, 94 patients fulfilled inclusion criteria. Median age was 42 years (14-84), 41% with >45 years, 58% males, 53% AA (Ann Arbor stage II-IV), 13% with ECOG performance status >1, 20% with IPS >3, 13% with low lymphocytes (<8% or<600/mm^3. Response was as follows: 77 (82%) achieved complete response (CR), 5 (5%) partial response and 8 (8%) progression. 86% of global survival at 5 years and 82% of progression free survival at 5 years. With a median follow-up of 65 months, 10 second cancers and one concomitant malignancy were diagnosed in 94 patients: 7 respiratory tract malignancies, 2 gynecological cancers and 1 digestive tract cancer. The concomitant cancer was a breast cancer. Different factors at the time of diagnosis were associated in our patients with an increased incidence of secondary malignances. Univariate analysis showed that age >45 years, being smoker, IPS>3, low lymphocytes and advanced stage (III-IV) increased significantly the risk of secondary neoplasms (Table I). Multivariate analysis showed that only having >45 years (relative risk 14; 95 percent confidence interval, 1.6-125.9), lymphocytes <1010/mm^3 (relative risk 6.4; 95 percent confidence interval, 1.3-31.7) and being smoker (relative risk 4.1; 95 percent confidence interval, 0.7-24.2) retained independent significance. The number of cycles of ABVD received and the radiotherapy were not related with an increased incidence of secondary malignancies.
Summary/Conclusion: Patients with risk factors at diagnosis such as: smoking history, low lymphocytes and<45 years had an increased incidence of secondary neoplasms during the next years after ABVD. We conclude that it is important to emphasize, in this type of patients, the establishment of optimal prophylactic and screening strategies.

PB2014

PD-1 INHIBITORS IN THE TREATMENT OF RELAPSED AND REFRACTORY CLASSICAL HODGKIN'S LYMPHOMA

M. Kichigina*, G. Tumyan, E. Demina, Z. Pervin, I. Monin, O. Yakimovich, D. Tupitsina, Z. Shikhabova

Hematology, National Medical Research center of oncology named after N.N. Blochina, Moscow, Russian Federation

Background: The main problems in the modern treatment of classical Hodgkin's lymphoma (cHL) are patients with refractory disease and relapses after ASCT. The most promising for this category of patients seems to be the use of a new class of monoclonal antibodies-PD-1 (nivolumab, pembrolizumab)/ They block the interaction between the receptor of PD-1 on activated T-lymphocytes and its ligands (PD-L1, PD-L2) on tumor cells, simulate the antitumor immune response.
Aims: evaluate the effectiveness and safety of therapy of a new class of monoclonal antibodies-PD-1 (nivolumab).
Methods: According to the NPP program" in N.N. Blokhin National Cancer Research Center 12.2015 to 09.2017 treatment with Nivolumab was given to 18 patients with relapses\refractory cHL. The median ages are 35 years. The median line of the therapy before the nivolumab was 4 (2-8): 13 (72%) patients underwent ASCT, 4 were not candidates for autograft, 3 received treatment brentuximab vedotin (1 with autograft, 2-only BV). ECOG was predominantly 2, in 3 patients-3. Nivolumab was administered at a dose of 3 mg/kg every 2 weeks before the progression or realization of adverse events (AEs). The median number of treatment courses is 25 (1-44). The effect of therapy was assessed in 17 patients, 1 patient was excluded from the evaluation due to the development of serious AE after the first administration.
Results: Treatment was effective in 53% of patients (9 patients), of whom full remissions (PR) were achieved in 29% (5 patients). Stabilization with a median duration of the effect of 15 months was found in 7, and in 1 patient-progression after 9 injections of nivolumab. By 09.2017 16 out of 17 patients are alive, in whom the effect is estimated, 9 of them remain without progression, including all 5 patients with PR. From the progression of LH died 1 patient. With median follow-up of 18 months (from 1 to 27 months), the median survival to progression was 16 months, overall survival was 94%. It should be noted that all but the patient with progression and the patient withdrawn from treatment in connection with the development of AE, noted a significant clinical improvement and an increase in general status to ECOG 0-1. Of the complications of treatment, Herpes zoster (1), community-acquired pneumonia (3), transient elevation of transaminase levels>4 norms (1) were noted. One patient had a serious immune-mediated reaction (demyelination) after the first administration of nivolumab, which caused the drug to be discontinued.
Summary/Conclusion: Immunotherapy with PD-1 inhibitors (nivolumab) is highly effective in relapses and refractory cHL, it has moderate toxicity, however, the possibility of developing immune-mediated reactions requires further accumulation of material and additional attention of the physician.

PB2015

A CLINICAL CASE OF IMMUNE THROMBOCYTOPENIA ASSOCIATED WITH PD-1 INHIBITOR (NIVOLUMAB) TREATMENT IN A PATIENT WITH RECURRING HODGKIN'S LYMPHOMA

M. Platonov[1,*], S. Moiseev[1], N. Michailova[2]

[1]Hematology, ARCERM EMERCOM of Russia, [2]Hematology, Raisa Gorbacheva Memorial Institute of Children's Hematology and Transplantation, Sankt-Petersburg, Russian Federation

Background: PD-1 ligand inhibitors are widely used nowadays for treating melanoma, non-small cells lung cancer, head and neck cancer, Hodgkin's

lymphoma. Severe hematological side effects of treatment with PD-1 inhibitors (Nivolumab, Pembrolizumab) have only been described in the form of third or fourth degree neutropenia. No cases of isolated thrombocytopenia in connection with PD-1 inhibitor therapy have been reported before. Presented here is the clinical case of a Hodgkin's lymphoma patient successfully treated with Nivolumab while having developed isolated reversible immune thrombocytopenia.
Aims: The case traces the dynamics of severe immune thrombocytopenia in a female patient with Hodgkin's lymphoma who, despite having developed fourth degree thrombocytopenia, was continually treated with Nivolumab undergoing dose adjustment and Cyclosporine therapy.
Methods: Blood cells count assessment was used to evaluate a single patient's clinical case within a sixteen-month period of consecutive Nivolumab treatment.
Results: A thirty-eight year-old female diagnosed with stage IIB chemoresistant Hodgkin's lymphoma received PD-1 inhibitor Nivolumab starting September 2016 as immune therapy for her primary condition, at a dose of 3 mg/kg every two weeks. In January 2017, fourth degree thrombocytopenia at count of $3x10^9$/l was detected after 10^{th} injection, accompanied by petechial skin rash on lower extremities. No anemia or leukopenia was found. Prednisolone pulse therapy with continued administration at a dose of 2 mg/kg per day had no effect within a month. After that, the therapy was supplemented with Cyclosporine at a dose of 3 mg/kg per day, which, at the end of March 2017, was followed by the Nivolumab injection renewal at a dose of 1 mg/kg at the same interval. Cyclosporine was used as an immune suppressor with ability to prevent cytokine gene transcription in activated T-cells. Further on, the patient demonstrated thrombocyte count increasing to normal and subnormal levels despite continuous treatment with Nivolumab. By the end of September 2017, baseline thrombocyte value was restored, and in accordance with that, the Cyclosporine dose was gradually reduced to a total withdrawal and the Nivolumab dose elevated up to 2 mg/kg per day. To this date (January 22, 2018) the patient remains in full PET-negative remission of Hodgkin's lymphoma. Her thrombocyte count is $167x10^9$/l.
Summary/Conclusion: From that clinical case of Hodgkin's lymphoma patient, we saw that isolated immune thrombocytopenia could not be a sole reason to stop PD-1 inhibitor therapy if adequate measures to mitigate autoimmune activity were taken. Addition of Cyclosporine for our patient suppressed activated T-lymphocytes without reducing the clinical effect of Nivolumab therapy.

PB2016

REAL WORLD DATA ON THE EFFICACY AND SAFETY OF BRENTUXIMAB VEDOTIN IN RELAPSED/REFRACTORY HODGIN LYMPHOMA IN SLOVAKIA

M. Ladicka[1,*], L. Sopko[2], J. Chudej[3]

[1]Hematooncology, National Cancer Institute, [2]Hematology, University Hospital, Bratislava, [3]Hematology, University Hospital, Martin, Slovakia

Background: Brentuximab vedotin (BV) is an antibody-drug conjugate (ADC) that selectively delivers monomethyl auristatin E, an antimicrotubule agent, into CD30-expressing cells. A phase I and II studies with BV demonstrated significant activity with favourable safety profile in patients with relapsed and refractory (R/R) CD30 positive lymphomas.
Aims: To evaluate epidemiological data and the impact of BV on survival in R/R Hodgkin lymphoma (HL) patients.
Methods: This is a retrospective analysis of 51 patients with R/R HL treated at three Slovak centers from 1/2014 to 12/2016. Fifty one patients received BV treatment in the period from 07/2012 to 02/2017. Bretuximab vedotin was administrated intravenously in the dose of 1.8 mg/kg every 3 weeks.
Results: In brief, the median age at the time of diagnosis was 33 years. In addition, the median age of participants at the time of initiation of our study was 38.8 years. Median time from the first-line therapy to BV treatment was 28 months. In total, 35 patients (70.0%) had R/R HL within 1 year after the end of last treatment. Based on clinical judgment, the treating physician categorized participants as eligible (n=39) or ineligible (n=11) for autologous stem cell transplantation (ASCT). The median number of previous lines of the therapy was 5 in ASCT-eligible patients and 3 in ASCT-ineligible patients. The progression free survival (PFS) was 7.0 months for 32 patients who did not undergo SCT. In patients (n=8) who achieved complete (CR) or partial remission (PR), the PFS was 34 months. On the other hand, 24 patients with stable disease (SD) or disease progression had PFS only 4.9 months. The median PFS for patients (n=13) treated with BV therapy and immediately followed by allogeneic stem cell transplant (aloSCT) has not been reached. In patients (n=5) who had undergone chemotherapy followed by aloSCT, PFS was only 5.8 months (Figure 1). We have identified 29 patients who underwent ASCT with at least one risk factor for relapse or disease progression. The most common risk factor was early progression after first-line treatment. The patients underwent BV treatment with a median of 8 cycles, and 4 patients (8%) completed 16 cycles of the treatment. BV dose was reduced in 16% of patients; most common reasons were anemia, neutropenia and thrombocytopenia existing prior to initiating BV treatment, toxicity during the treatment was reason for reduction only in one patient.

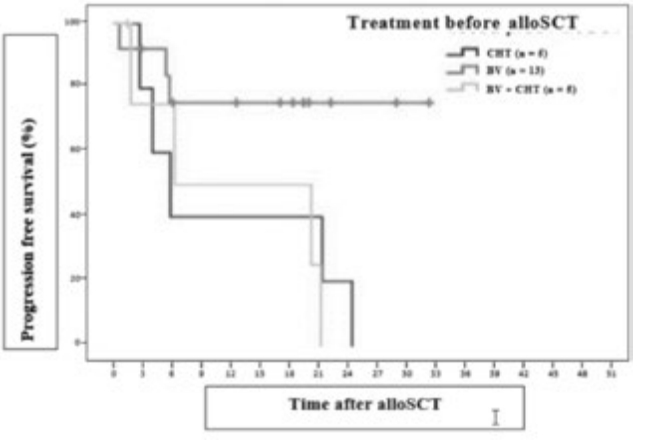

Figure 1.

Summary/Conclusion: Our study included patients in second or further line of therapy. Overall, 70% of patients had documented R/R HL within 1 year after the end of last treatment. No severe toxicity related to BV regimen was observed. Improved outcomes were observed in patients who achieved a complete remission on BV. BV use pre-allogeneic SCT is associated with a rapid response in a majority of patients with R/R HL compared with standard chemotherapy. Therefore, BV may represent also an optimal therapeutic option as a bridge to aloSCT in R/R HL patients. Our analysis confirmed BV efficacy in heavily pretreated R/R HL patients in real clinical practice.

PB2017

EFFECT OF THE INITIAL TREATMENT ON THE MUSCLE MASS AND RESPONSE TO THERAPY IN HODGKIN'S LYMPHOMA

S. Kucukyurt Kaya[1,*], B. Bilgin[2], M. Metin Rusen[3], A. Yikilmaz Senturk[1], S. Dogan[1], M. Gunduz[4], S. Akinci[4], S.M. Bakanay[1], I. Dilek[1]

[1]Department of Hematology, [2]Department of Oncology, Ankara Yildirim Beyazit University, [3]Department of Radiology, [4]Department of Hematology, Ankara Ataturk Training and Research Hospital, Ankara, Turkey

Background: Loss of muscle mass has been reported to be an independent predictor of clinical outcome in multiple gastrointestinal cancers.
Aims: The decrease in the muscle mass may have an effect on the response to treatment in Hodgkin's lymphoma(HL). We aimed to investigate the effect of chemotherapy on muscle mass in HL patients.
Methods: This study included 37 newly diagnosed HL patients who were referred to our clinic between 2010 and 2017. Patients were diagnosed after lymph node biopsy and initial evaluation was done by either PET-CT or computarized tomography (CT) and were staged according to Ann-Arbor Staging System and Cotswolds modification. Body surface areas were calculated. All patients received Adriamycin 25 mg/m2, Bleomycin 10 mg/m2, Vinblastine 6 mg/m2, Dacarbazine 375 mg/m2 (ABVD) chemotherapy administered intravenously on Day 1 and Day 15. Following 4 courses of the ABVD, an interim evaluation was carried out with CT. The computed tomographic scans of the patients before the treatment and after 4 courses of ABVD were available in the Picture Archive and Communication System (PACS) of the hospital. The L3 vertebra was identified on the axial CT and the posterior paravertebral muscle was manually contoured bilaterally to determine the skeletal muscle index. L3 skeletal muscle index and fat-free mass were calculated. The decrease in the muscle mass was defined by the presence of the posterior paravertebral area less than the median of the cohort.
Results: The median age of the patients was 41 (19-76) and Male/Female =26/11. There were 18 early-stage (stage I-II) and 19 advanced-stage (stage III-IV) patients. Partial and complete responses were observed in 24 and 10 patients, respectively. Three patients progressed despite treatment. When the treatment-based change of the paravertebral muscle area was examined, there

was a statistically significant decrease in muscle area after 4 courses of treatment in both early and advanced stage disease (Table 1). There was no statistically significant difference between the early and advanced stage patients in terms of the pre-treatment paravertebral muscle area (p=0.46). When the subgroups were examined in terms of response to the treatment, there was no statistically significant difference in the basal muscle measurements of the patients with complete and partial responses and progression (p=0.44). However, a statistically significant decrease was determined in the paravertebral muscle area following the chemotherapy in patients with complete and partial response to the treatment; while there was a distinct but statistically insignificant decrease in the muscle mass in patients with progression (p values 0.028, 0.002 and 0.18, respectively). The ratio of decrease in the paravertebral muscle area are shown in Figure 1.

Table 1.

Table 1: Difference in paravertebral muscle area with 4 cycle chemotherapy

	Pre-treatment Paravertebral Muscle Area (cm^2)	Post-treatment Paravertebral Muscle Area (cm^2)	P
Entire Group	48.38	46.92	< 0.001
Early Stage (I-II)	49.55	48.08	0.002
Advance Stage (III-IV)	46.51	43.74	0.011

Summary/Conclusion: There was a significant decrease in the muscle mass after the chemotherapy for HL. However, more data is required to determine its association with response to treatment.

PB2018

HODGKIN LYMPHOMA: THE MOFFITT CANCER CENTER EXPERIENCE

A. Rose[1,*], A. Lim[1], A. Tungesvik[1], L. Isenalumhe[2], L. Sokol[2]

[1]Internal Medicine, University of South Florida, [2]Hematology/Oncology, H. Lee Moffitt Cancer Center, Tampa, United States

Background: Hodgkin lymphoma (HL) is a clonal disease of B-cell origin comprising about 10% of all malignant lymphomas. Classical HL (cHL) includes 4 histological subtypes: lymphocyte rich, nodular sclerosis, mixed cellularity and lymphocyte depleted. Nodular lymphocyte predominant (NLPHL) type is currently a separate entity. Greater than 75% of patients (pts) are cured with current treatment modalities. Prognosis is based on clinical stage, presence of systemic symptoms, presence of bulky disease and treatment rendered.
Aims: In this large single institution database of HL pts, we analyzed demographics, prognostic features, and survival over a 27 year period.
Methods: We evaluated 761 pts with Hodgkin Lymphoma diagnosed between 1990-2017 at Moffitt Cancer Center in this retrospective study. We estimated overall survival (OS) and various clinical and laboratory factors with a potential impact on survival by using the Kaplan Meier curve as well as Cox Proportional Hazards regression. The relationship between clinical features and prognosis was tested using frequencies and either the Chi-square test, Fisher's Exact test or the Cochran-Armitage trend.
Results: Among all patients, 55.3% were male and the majority were Caucasians (79.2%). Mean age at diagnosis was 38.5 years. 60% of pts were<39 years of age, 31% were 40-64 years old and 9% were 65 and older. Histological subtypes include nodular sclerosis 72.2%, mixed cellularity 19%, lymphocyte rich 3%, lymphocyte depleted 0.7%, and nodular lymphocyte predominant 5.1%. Stage at diagnosis; I-6.9%, II- 47.5%, III 22.7%, IV 22.9%. B-symptoms were present in 50.4% of pts, and 22.6% had bulky disease. 67.2% of pts with advanced stage disease (≥stage III) presented with B symptoms compared to 36.6% with early stage disease (≤stage II). Bulky disease revealed no correlation with the stage. There was a significant difference in mean age at diagnosis according histological subtypes; with nodular sclerosis more prominent at younger ages (35.7yrs) compared to lymphocyte depleted (50yrs) (p-value<0.05). The mean time of follow-up was 7.2 years and median survival was 17.8 years with a 5-year OS of 83.1% (CI: 80, 85.6%) and 10-year OS of 70.9% (CI: 66.4, 74.8%). Survival was significantly different among the age cohorts<39yrs, 40-65 and >65 years with 10-year OS survival of 73.4%, 71.7% and 47.3% respectively (p-value<0.001). Survival was longer in pts with NLPHL histology in comparison to the cHL subtypes. NLPHL had a median survival of 37.4 years with a 5-year OS of 96.9% (CI: 79.8, 99.6%) compared to cHL histology with a median survival of 16.8 years and a 5-year OS of 82.8% (CI: 79.4% *vs* 85.9%).
Summary/Conclusion: Our data suggests that pts with Hodgkin's lymphoma have very good long-term outcomes. Significant indicators of poor prognosis include classical histology type, advanced stage at diagnosis, presence of B symptoms, and advanced age. Outcomes based on treatment regimen are in progress.

PB2019

HODGKIN LYMPHOMA OF THE GASTROINTESTINAL TRACT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

M. Barzilai[1,*], I. Avivi[1], Y. Herishanu[1], C. Perry[1], R. Ram[1], Y. Ron[2], N. Sarid[1]

[1]Hematology, [2]Gastroenterology, Sourasky medical center, Tel Aviv, Israel

Background: Patients with inflammatory bowel disease (IBD) on immunosuppression are at risk of developing lymphoma, particularly primary gastrointestinal (GI) Non-Hodgkin lymphoma. Primary GI Hodgkin lymphoma (HL) in this setting is a rare and poorly defined clinical entity.
Aims: We report on a patient with Crohn disease (CD) who developed GI HL and review the available literature.
Methods: An electronic search of Medline, updated to December 2017, was performed .Each paper was reviewed and duplicate reports describing the same patients were included just once.
Results: Ten single-case studies and 6 case-series, published between 1978-2016, involving 23 patients ,were identified. Twenty-one (91%) patients had CD, whilst two others had ulcerative colitis. Eighteen (79%) patients were male, with a median age of 39 at lymphoma diagnosis. Diagnosis of HL occurred at a median of 8 and 4.4 years after the detection of IBD and commencing immunosuppression, respectively. HL had a predilection (80%) to involve the inflamed GI site. The histological subtype was mixed cellularity in 65% of cases and in-situ hybridization for EBV-encoded RNA, when documented, was positive in all cases. Thirty-five, 20%, 5% and 40% of patients were diagnosed in stage 1 to 4, respectively. Interestingly, 66% of patients with advanced disease had liver involvement. Immunosuppression was stopped in most (70%) patients upon lymphoma diagnosis. HL treatment consisted of chemotherapy only, surgery followed by chemotherapy or surgery only in 50%, 33% and 16% of cases, respectively. Four patients had IBD flare during HL remission.
Summary/Conclusion: Patients with IBD who develop HL with GI involvement have distinct characteristics: male predominance, a predilection for inflamed GI sites, mixed cellularity histological subtype, EBV positivity, and a unique pattern of spread to the liver.

PB2020

LONG-TERM FOLLOW-UP OF 2 PATIENTS TREATED WITH 90Y-RITUXIMAB RADIOIMMUNOTHERAPY FOR RELAPSE OF PREDOMINANTLY LYMPHOCYTIC NODULAR HODGKIN'S LYMPHOMA

S. Golstein[1,*], K. Muylle[2], M. Vaes[1], M. Vercruyssen[1], C. Spilleboudt[1], A. de Wind[3], D. Bron[1]

[1]Hematology, [2]Nuclear Medicine, [3]Anatomo-Pathology, Institut Jules Bordet, ULB, Brussels, Belgium

Background: Predominant lymphocytic nodular Hodgkin's lymphoma (NLPHL) is a rare lymphoma.
Aims: Life expectancy being more than 10 years, short term and long term life-threatening toxicities should be avoided. However, there are no evidence-based guidelines for initial treatment or relapse.
Methods: Two patients relapsing 12 and 17 months after initial treatment with rituximab were included in a prospective phase II trial of radioimmunotherapy (RIT). Yttrium 90 was coupled to rituximab (^{90}Y-rituximab) and administered according to the following protocol : a first infusion of rituximab 250mg/m^2, repeated one week later and directly followed by the injection of ^{90}Y-rituximab (14,8 MBq/kg). The rational of using unlabeled ("cold") antibodies before injecting ^{90}Y-rituximab is to reduce tissue toxicity of RIT by providing a more favorable biodistribution profile of the radiolabeled antibody (Vaes M. *et al.* J Cancer Sci Ther 2012).
Results: Case # 1: A 27 years old Mediterranean man noticed in April 2008 a bulky right axillary mass, CS IA.A biopsy was performed and the diagnosis of NLPHL, CD20+ was established. The first line treatment consisted in radiation therapy (RT) and 4 weekly administrations of Rituximab. The ^{18}FDG-PET/CT performed 6 months after the treatment showed a complete metabolic response but after 18 months a moderate hypermetabolic activity in infracarinal lymphadenopathies and beside the spleen is described. In June 2010, the relapse is confirmed showing lymph node involvement in the right pelvic region, the splenic hilus and the left axillar region. The patient accepted to be enrolled in a RIT protocol in October 2010. This treatment induced a complete remission which is still ongoing after 7 years. No adverse events were reported. **Case #2:** A 38-year-old Caucasian man

presented with small bilateral cervical and supraclavicular lymphadenopathies. A biopsy was performed and showed a NLPHL (CD30 +, CD20 +) stage IIIA. ^{18}FDG-PET/CT confirmed cervical but also juxta-centimetric retroperitoneal lymph nodes and rituximab treatment (4 weekly courses) was started in August 2007. Response assessment by^{18}FDG-PET/CT, performed 4 months after the end of the treatment, showed a complete metabolic response. Eleven months after the end of treatment, ^{18}FDG-PET/CT revealed a 2cm diameter retroperitoneal lymph node which increased to 5 cm in diameter at 21 months concomitantly with hypermetabolic retroperitoneal lymph nodes. RIT was started in September 2009, according to our study protocol. No side effects were reported during and after treatment. Six months after RIT, ^{18}FDG-PET/CT showed a complete metabolic remission, persisting until today, 8 years later.
Summary/Conclusion: There are no prospective randomized studies to guide the therapy in NLPHL. Radiotherapy plays an essential role in early stages and chemotherapy combined with anti-CD20 antibody is very effective in advanced diseases. We opted for salvage treatment with RIT to treat two young patients with early relapsed NLPHL. A complete response was maintained for 7+ years compared to less than 2 years after rituximab alone. To our knowledge, RIT has never been reported for this indication.

PB2021

SUCCESSFUL TREATMENT WITH NIVOLUMAB OF HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS SECONDARY TO REFRACTORY HODGKIN LYMPHOMA. A CASE REPORT

C. Cantò*, E. Finolezzi, S. Luciani, E. Ranucci, F. Angrilli

Dipartimento di Ematologia, Biotecnologie e Medicina Trasfusionale, PO "Spirito Santo", Pescara, Italy

Background: Hemophagocytic lymphohistiocytosis (HLH) is an infrequent but potentially life-threatening hyperinflammatory syndrome that occurs in about 6% of patients affected by Hodgkin Lymphoma. Treatment of secondary HLH includes corticosteroids, cyclosporine A, etoposide and/ or malignancy-directed therapies. Anecdotal cases report successful results with Alemtuzumab, Infliximab, Daclizumab, Blinatumomab and Ruxolitinib.
Aims: We describe a case of HLH complicating refractory classical Hodgkin lymphoma (cHL) that resolved only after treatment with Nivolumab. At our knowledge, this is the first case reported.
Methods: A 21-year-old man was diagnosed with cHL, CS IIIB, in September 2014. He was refractory to five lines of treatment (ABVD, IGEV, Brentuximab Vedotin, Bendamustine and Beacopp). In April 2016 he developed fever, marked splenomegaly and grade 4 pancytopenia. Other laboratory findings showed hypoalbuminemia, hypertransaminasemia and hyperbilirubinemia; antibody tests for HCV, HBV, HIV, HSV, CMV and EBV infections were negative. The bone marrow biopsy showed the presence of numerous macrophages embedding hematopoietic elements, without lymphoma infiltration. Consequently, HLH was diagnosed. Treatment with corticosteroids and etoposide was ineffective. In May 2016 he started treatment with Nivolumab (in the setting of the Italian Extented Access Program) at the dose of 3 mg/kg every 14 days.
Results: Until Nivolumab treatment was started the patient required transfusion support with 14 PRBC Units and 19 Plt Units. After the first administration of Nivolumab he developed an episode of respiratory insufficiency infusion related that resolved with mild corticosteroid therapy. The patient became transfusion independent after the third dose of Nivolumab. After 32 doses of Nivolumab, in November 2017 treatment was stopped because of a severe pancreatitis treatment related. Unfortunately in February 2018 the patient died in complete remission in a road accident.
Summary/Conclusion: HLH is a potentially fatal hyperinflammatory disease induced by a pathologic immune activation, with proliferation of well-differentiated macrophages/histiocytes and increased phagocytic activity. The tumor in cHL is mainly composed of inflammatory cells providing a protective niche to the sparse CD30-positive malignant HRS cells. Intriguingly, an increased number of tumor-associated macrophages (TAM) was strongly associated with treatment failure and shortened survival in patients with cHL. TAM can express PD-1 and this suggests that anti-PD-1 therapies may also function through a direct effect on macrophages. Left untreated, the prognosis of HLH is poor and generally fatal. Therefore, prompt recognition and timely treatment are critical. Usually, in patients who present with secondary HLH, treatment of the underlying cause can lead to control and resolution of HLH. At the onset of HLH, our patient had a chemorefractory cHL and conventional treatment of HLH was totally ineffective. The anti-PD1 antibody nivolumab induce a high overall response rate in relapsed/ refractory cHL. In our patient nivolumab induced a prompt control of HLH and a subsequent complete remission of cHL. More knowledge is warranted about interactions between macrophages and PD-1/PDL-1 inhibitors.

THE PERIPHERAL BLOOD ILC, AND TH-17 RELATED CYTOKINE PRODUCTION ARE IMPAIRED IN A CHILD WITH A NOVEL MUTATION IN ITK WHO PRESENTED WITH RELAPSED HODGKIN LYMPHOMA

M. Cansever[1], A. Eken[2], I. Somekh[3], N. Zietara[3], A. Ozcan[4], M. Karakukcu[5], M. Rohlfs[3], E. Unal[4], C. Klein[3], T. Patiroglu[4,*]

[1]Department of Pediatrics, Division of Pediatric Immunology, [2]Department of Medical Biology, Erciyes University, Faculty of Medicine, Kayseri, Turkey, [3]Dr von Hauner Children's Hospital, University Hospital, Ludwig Maximilians University, Munich, Germany, [4]Erciyes University, Faculty of Medicine, [5]Erciyes University, Faculty of Medicine,, Department of Pediatrics, Division of Pediatric Hematology-Oncology, Kayseri, Turkey

Background: Common immunological features in patients with interleukin-2-inducible T-cell kinase (ITK) deficiency include: CD4 + T cell loss along with absolute lymphopenia and progressive hypogammaglobulinemia. *iNKT* cells are severely reduced in the peripheral blood of ITK deficient patients; hence a critical role has been postulated for *iNKT* cells in the response to EBV infection.
Aims: Herein we report a child with a novel ITK mutation who showed impaired peripheral blood innate lymphoid cells, and Th-17 related IL-17A, IL-22, and GM-CSF cytokine production.
Methods: A Previously healthy (5 year old ?) patient, from a consanguineous family was admitted to the hospital with complaints of unilateral swelling on of the neck. Biopsy was compatible with Hodgkin lymphoma and she was treated with ABVD/COPP protocol, but she experienced an early relapse just one year after completing chemotherapy. ICE regimen followed by autologous transplantation was performed. After transplantation she had hypogammaglobulinemia and persistent and fatal EBV infection. Next generation sequencing returned a homozygous frame-shift variant in ITK (LRG_189t1: c.328delA: p. Thr110Argfs Ter1551.) The variant was confirmed by Sanger sequencing and segregated with the disease. This variant has not been previously described. but variants in ITK are described to cause lymphoproliferative syndrome with splenomegaly and hepatomegaly, as well as anemia, thrombocytopenia and pancytopenia. We report impaired CD3/CD28 induced proliferation by T cells. Itk mutant cells were more apoptotic without or upon TCR activation. Additionally, T cells produced less IL-17A, IL-22, and GM-CSF. Conversely, IFN-γ production was increased. Lastly, we analyzed peripheral ILC populations and observed reduced ILC3.
Results: Although it has previously been reported that TH-17 cytokine levels are impaired in ITK deficient mice, we report for the first time that peripheral blood innate lymphoid cells, and Th-17 related cytokine production are impaired in a child with a novel ITK mutation.

PB2023

THE PROGNOSTIC SIGNIFICANCE OF EXTRANODAL DISEASE IN HODGKIN'S LYMPHOMA

B. Sidi Mohamed El Amine*, H. Asma, O. Fouzia, S.A. Najet, B. Soraya, Z. Zahia

Universitary hospital of Sidi Bel Abbés, Sidi Bel Abbes, Algeria

Background: Hodgkin's lymphoma (HL) is a highly curable disease. Usually confined to the lymph nodes, extranodal involvement can occur and has an independent prognosis value.
Aims: To analyze the presenting features and the prognostic significance of extranodal disease in HL.
Methods: We performed a retrospective single institution study of 155 HL cases; from January 1992 to December 2010. The median age was 27 years (range, 15-80 years), Stages III-IV were present in 85 (54.8%) patients. Combined radio-chemotherapy was administered to 95 (61, 2%) patients and chemotherapy alone to 60 (38.8%). We analyzed the prognostic relevance of extranodal involvements and their significance was tested according to response rate an overall survival (OS).
Results: Extranodal disease was documented in 52 patients (33.5%) and 49 (44%) had bulky disease. Extranodal sites included the liver in 21 (13.5%), bone marrow in 11 (7%), pleura in 5 (3%), pharynx in 5 (3%), bone in 10 (6%), lung in 4 (1, 7%) and eye in 1 (0, 6%). The 52 patients with extranodal disease had poor prognosis compared with the nodal group (5 year OS, 51% *versus* 75%; p<0.001). Compared with the nodal subset, the extranodal patients presented more frequently with advanced stage disease (92% *vs* 08%; p<0.0001), B symptoms (90% *vs* 10%; p=0.002), a significantly low serum albumin (63.4% *vs* 24%; p<0.001) and a higher ESR (77% *vs* 23% p=0.005). Complete remission rates in the extranodal and the nodal subsets of patients were 65% *vs* 84% (p<0.001).

Summary/Conclusion: In our study, extranodal disease in patients with HL is frequent, especially in advanced stages, associated with a poor outcome and might be eligible for more effective treatment approach.

PB2024

A FAMILIAL REPORT OF MIXED CELLULARITY HODGKIN'S DISEASE(HD): THE SAME SUBTYPE HD, EBV NEGATIVE, WITH DIFFERENT OUTCOME

M. Moschovi*, A. Lagos, C. Tsipou, N. Tourkantoni

Hematology-Oncology Unit, [1]st Department of Pediatrics, National and Kapodistrian University of Athens, Athens, Greece

Background: Mixed cellularity Hodgkin's disease(HD) is a subtype of classic HD constituting the second most common type and 15-30% of all cases of HD. It is mostly observed in patients with either Epstein-Barr virus (EBV) or Human Immunodeficiency Virus (HIV) infection, having less inheritance rate comparing to other subtypes.
Aims: Presentation of two identical cases among siblings with different outcome.
Methods: Two siblings, a girl and a boy, were presented with mixed cellularity Hodgkin disease. Both, had the same histological subtype, the same stage(IIIs), the same location of the disease and both, at the biopsy specimen, where negative for EBV infection. The only apparent difference between the two cases was the presenting age. The girl was diagnosed at the age of 15 years old and the boy at the age of 25 years old. Both of them received chemotherapy. The girl achieved remission with chemotherapy only. The boy received initially only chemotherapy. Due to the relapsed disease during chemotherapy, radiotherapy was added but he succumbed from refractory disease.
Results: The two cases were siblings. They had the same histological subtype of the disease, the same location, different age of onset but eventually different outcome. The girl received chemotherapy according to the SIOP HD protocol, and till now she is in first remission, 10 years after the diagnosis. By contrast, the boy had a poor outcome.
Summary/Conclusion: Considering that both cases where identical on their anatomical and histological characteristics and also both of them where negative for EBV infection, we conclude that the different age of onset of this subtype of HD, and the different gender, play a crucial role on the outcome. Local genetic predisposing factors may contributed to these familial HD cases.

Indolent Non-Hodgkin lymphoma – Clinical

PB2025

RISK FOR REACTIVATION OF HEPATITIS B INFECTION-IMPROVING TESTING PRE-IMMUNOCHEMOTHERAPY

C.L. Neoh*, M. Rogers

Haematology, Royal Surrey County Hospital, Guildford, United Kingdom

Background: Immunochemotherapy is an important treatment modality in haematological malignancies and hepatitis B virus (HBV) reactivation is known to occur following this. Although it is more commonly seen in patients with positive hepatitis B surface antigen (HBsAg), it can also occur in patients who are negative HBsAg but have detectable anti-HBV core antibody (anti-HBcAb), indicating past 'resolved' infection. Hence, patients should be screened for both HBsAg and anti-HBcAb prior to commencing immunochemotherapy that are known to increase risk for HBV reactivation. Patients with positive anti-HBcAb can often still be treated with immunochemotherapy but require antiviral prophylaxis, joint-care with a gastroenterologist and close monitoring of viral blood tests. An audit was initially conducted to assess the rates of HBV screening among patients being commenced on rituximab-containing regimens in the haematology department at Royal Surrey County Hospital (RSCH). This audit demonstrated that significant numbers of patients were not being screened fully and remedial measures were put in place. Following that, a re-audit was conducted to assess compliance rates post-intervention. Some studies have also shown HBV reactivation during treatments with ibrutinib, lenalidomide and obinituzumab, therefore we have included this cohort of patients in the re-audit. This re-audit showed that haemato-oncologists' practice on appropriate HBV screening can be improved to minimise risk of HBV reactivation.
Aims: To assess compliance with full HBV screening (HBsAg and anti-HBcAb) in patients receiving rituximab, ibrutinib, lenalidomide or obinutuzumab containing regimens at Royal Surrey County Hospital following remedial measures after the previous audit.
Methods: Patients who had been commenced on regimens including rituximab, ibrutinib, lenalidomide or obinutuzumab under the haemato-oncology unit were identified from the ARIA chemotherapy e-prescribing system. This included patients on regimens commencing 01/01/2017 to 24/11/2017. Winpath system was used to check for HBV testing over the last 10 years.
Results: 64 patients were identified; of which 54 patients on rituximab-containing regimens, 6 on ibrutinib, 3 on lenalidomide and 1 on obinutuzumab. This re-audit has clearly shown that there has been an improvement in rates of full HBV testing prior to treatment with immunochemotherapy. This was evidenced by an improvement from 7% to 56%. However, there were still a quarter of patients who did not have any HBV testing at all (only showing a modest improvement from 29% to 25%).

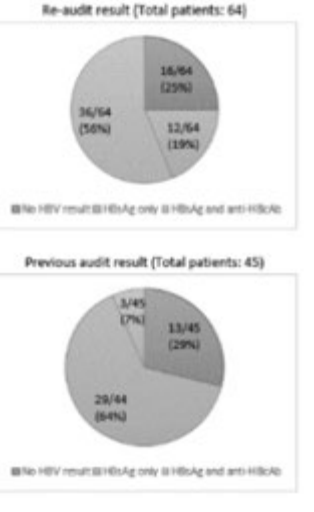

Figure 1.

Summary/Conclusion: This result has clearly shown that there is a need to assess haemato-oncologists' practice in ensuring a full HBV testing is done prior to commencing immunochemotherapy agents which are recognised as risks for HBV reactivation. Appropriate remedial measures have shown

to improve compliance rates. In our cohort, of all the patients who had a complete screening of both HBsAg and anti-HBcAb, 2 were found to be positive anti-HBcAb and received appropriate viral prophylaxis and regular HBV DNA viral load monitoring. This highlighted the importance of a proper screening prior to subjecting the patients to reactivation risks. In conclusion, a significant improvement in HBV testing rates has been achieved. However, ongoing efforts are required to bring about further improvement to ensure patient risks are minimised.

PB2026

CASTLEMAN DISEASE WITH THE EXPERIENCE OVER 17 YEARS

F.D. Atilla[1], N. Soyer[2], M. Tombuloglu[1], F. Vural[2], F. Sahin[2], M. Tobu[2], D. Demir[3], N. Ozsan[3], M. Hekimgil[3], G. Saydam[1,*]

[1]Hematology, [2]EGE University, Izmir, Turkey, [3]Pathology, Ege University, Izmir, Turkey

Background: Castleman disease (CD) is a non-clonal lymphoproliferative disorder as a common cause of non-neoplastic lymphadenopathy. CD encompasses several distinct clinicopathological disorders at the intersection of haematology, immunology, oncology, rheumatology and virology that share a spectrum of histopathological features. An international collaborative working group has reached consensus definitions and classification, defining diagnostic criteria for CD which enables to clinicians reaching the proper diagnose.
Aims: The aim of this study is to review our CD patients from a single centre according to newly established diagnostic criterias.
Methods: All patients with a biopsy proven histopathological characteristics of CD diagnosed at Ege University Hospital between 2000-2017 years were reviewed for analysis. Clinical and laboratory datas were collected retrospectively. The patients were divided into two main groups based on the anatomical distribution of the disease: Unicentric CD (UCD) and multicentric CD (MCD). Also MCD were divided into two groups: HHV8 positive MCD and idiopathic MCD.
Results: A total of 64 patients were reviewed. Among the study group; 34 patients were excluded because two were diagnosed with synchronous Hodgkin lymphoma, one was diagnosed with POEMS, and the rest were unable to access all data. Detailed clinical and laboratory datas were summarized in Table 1. The mean age at diagnosis of 30 patients with adequate data was 48.8 (26-82). After histopathological evaluation, majority had hyaline vascular type (n=19), followed by mixed type (n=8) and plasma cell type (n=3). There were 16 patients in UCH group, none of them had HHV-8 and HIV positivity. After a median follow up of 54 months, the estimated 2-year OS was 87.7% [95% confidence interval (CI): 72.1–103.3]. There were 7 patients in the HHV-8+MCH group and two of them had Kaposi sarcoma. All of whom received chemotherapy and/or immunotherapy treatments. Clinical manifestations in the HHV-8+MCH group were; fever, splenomegaly, skin lesions, acute renal failure, oedema, effusion, respiratory symptoms, CRP/ferritin and LDH elevation. After a median follow up of 38.2 months, the estimated 2-year OS was 46% [95% confidence interval (CI): 17.1–74.9]. There are 7 patients in the iMCH group with HHV-8 negative and the clinical findings are very similar to the HHV-8+MCH group. Two-year overall survival in iMCH group was higher than HHV-8+MCH with 82.7% [95% confidence interval (CI): 58.6–106.8].
Summary/Conclusion: CH is a very rare lymphoproliferative disease which should be kept in mind in the differential diagnosis with asymptomatic and localized lymphadenopathies or widespread lymphadenopathies with severe systemic symptoms. Future studies should be multicentred and collaborative in order to evaluate significant numbers of patients and to establish up to date and effective treatment protocols for this rare but potentially life-threatening disorder.

PB2027

RITUXIMAB MAINTENANCE IMPROVES SURVIVAL IN FOLLICULAR LYMPHOMA: A RETROSPECTIVE NATIONWIDE REAL-WORLD ANALYSIS FROM TAIWAN CANCER REGISTRY

H.-H. Huang[1,*], Y.-C. Wen[2], H.-M. Chen[2], F.-Y. Hsiao[2,3,4], B.-S. Ko[1]

[1]Division of Hematology, Department of Internal Medicine, National Taiwan University Hospital, [2]Graduate Institute of Clinical Pharmacy, [3]Health Data Research Center, [4]School of Pharmacy, National Taiwan University, Taipei City, Taiwan, Republic of China

Background: Follicular lymphoma (FL) is the most frequent type of indolent lymphoma in western countries, but it is less frequent in Asia. Several trials have demonstrated the progression-free benefit of rituximab maintenance (R-maintenance) in FL in western countries. However, the overall-survival benefits of R-maintenance in Asian FL patients remain uncertain.
Aims: We utilized the Taiwan Cancer Registry Database (TCRD), the National Death Registry Database (NDRD), and the National Health Insurance Research Database (NHIRD) to investigate the clinical importance of R-maintenance for newly diagnosed FL patients in Taiwan.
Methods: From TCRD, we identified 836 patients with newly diagnosed FL during 2009 to 2012. We retrieved the clinical information from NHIRD, and the survival status from NDRD. We enrolled patients with stage II-IV diseases and receiving 4-8 cycles of rituximab containing frontline chemotherapies. We excluded those who died or received chemotherapies again within 180 days after the end date of the frontline therapies. Total 396 patients were included. Their demographics, clinical parameters, overall survival (OS), and time to next treatment (TTNT) were subjected for analysis.
Results: Among the 396 patients, 260 underwent R-maintenance, and 136 served as the observation group. Compared with the observation group, the R-maintenance group had similar distribution in age, gender, Ann Arbor stages, Charlson Comorbidity scores and the sites of the practice setting. However, those with R-maintenance underwent less intensive frontline chemotherapies (less R-CHOP receiving rate; 53.5% in R-maintenance, *versus* 66.2% in observation; *p* value 0.0150) and less cycles of rituximab-containing frontline therapies (the rate of receiving 7-8 cycles frontline therapies, 25.8% in R-maintenance, *versus* 41.9% in observation; *p* value 0.0010). The patients receiving R-maintenance had a significantly better OS in univariate analysis (hazard ratio (HR), 0.43; 95% confidence interval (CI), 0.20-0.91), and even in multivariate analysis (HR, 0.42; 95% CI, 0.19-0.91). In the multi-variate analysis, age older more than 60 years and stage IV disease also showed negative impacts on OS. On the other hand, the TTNT was similar in the R-maintenance and observation groups (multivariate analysis, HR, 0.96; 95% CI, 0.65-1.42).

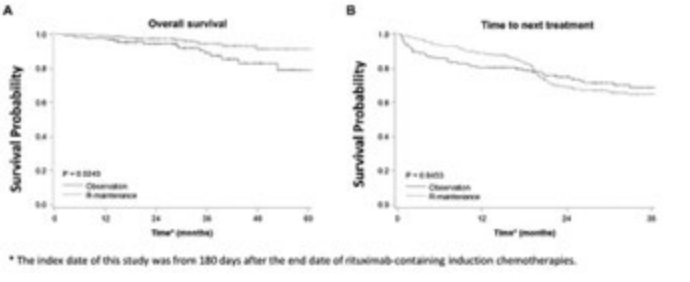

Figure 1.

Summary/Conclusion: Our study is the first real-world study to demonstrate the OS benefit of R-maintenance after the frontline therapies in newly diagnosed FL patients of Asian population.

PB2028

Abstract withdrawn.

PB2029

THE IMPACT OF FIRST COMPLETE REMISSION BY PET-CT AND TIME TO NEXT TREATMENT ON OVERALL SURVIVAL OF FOLLICULAR LYMPHOMA PATIENTS

T.-D. Tan[1,*], L.-W. Chiou[1], J.-S. Wu[2], M.-Y. Lee[3], Y.-Y. Huang[4], S.-S. Chen[5], J.-W. Lee[6], P.-Y. Chen[1], M.-T. Sung[1]

[1]Hematology and Medical Oncology, [2]Radiation Oncology, [3]Pathology, [4]Nuclear Medicine, [5]Radiology, [6]Epidemiology and Biostatistics, Koo Foundation Sun Yat-Sen Cancer Center, Taipei City, Taiwan, Republic of China

Background: Rituximab alone or combined with chemotherapy is the treatment of choice for follicular lymphoma and we retrospectively analyzed the impact of PET-CT complete remission (CR) and time to next treatment (TTNT) on outcome of follicular lymphoma patients.
Aims: To investigate the importance of PET-CT CR and TTNT on overall survival.
Methods: Between 2002 and 2014, we have 174 follicular patients treated at our institute and 150 patients can be evaluated the treatment response and long-term outcome.
Results: The CR after first line treatment with either R-COP or R-CHOP is 89% and PR 7% and 10-year overall survival is 62.6%. Eleven percent of patients died of lymphoma and 3% died of other causes. Forty seven patients

(31%) underwent second line of treatment with 19 (40%) TTNT shorter than 24 months and 28 (60%) longer than 24 months. There is no difference of overall survival between R-COP (86%) *versus* R-CHOP (77%) in 5 years, but there is trend to have more next treatment event in R-COP group as compared with R-CHOP group (60% *vs* 35% on 8-year follow up). There is no difference of overall survival between with or without rituximab maintenance. For PET-CT response, there is significant overall survival difference between CR and PR patients (88% *vs* 70%, p<0.001), and longer TTNT is seen in initial CR patients. TTNT longer than 24 months have better overall survival as compared with shorter than 24 months patients (93% *vs* 54% on 5-year).

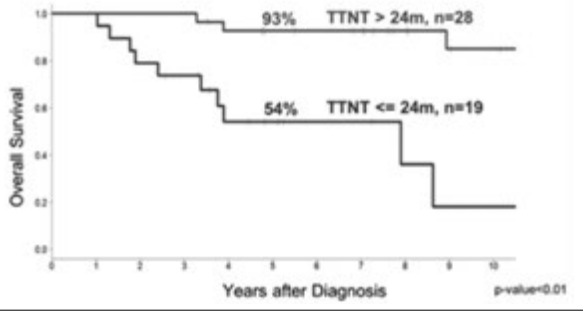

Figure 1.

Summary/Conclusion: Initial PET-CT CR patients have better overall survival as compared with PR patients and PET-CT CR should be the treatment goal on initial treatment. Besides, TTNT longer than 24 months patients have better outcome as well.

PB2030

EFFICACY OF RITUXIMAB PLUS BENDAMUSTINE REGIMEN AS FIRST OR SECOND LINE TREATMENT IN WALDENSTRÖM'S MACROGLOBULINAEMIA

L. Poetsch[1], F.-X. Gros[2,*], M.-S. Dilhuydy[2], C. Gary[3], N. Milpied[2], K. Bouabdallah[2]

[1]Hematology, F-3000, CHU Bordeaux, [2]Hematology, [3]Pharmacy, F-33000, Bordeaux, Bordeaux, France

Background: Waldenström's macroglobulinaemia (WM) is a rare lymphoid disorder that represents 1-2% of hematological neoplasms. There is no standard frontline therapy for WM although Rituximab and an alkylating agent are recommended (*Buske, Ann Oncol 2013*). Bendamustine plus Rituximab (BR) is an effective regimen for relapsed WM (*Tedeschi, Leukemia Lymphoma 2015* ; *Rummel, Lancet 2013*) and is routinely used in our center since 2010.
Aims: To evaluate the efficacy of BR regimen in Wladentrom's Macroglubulinemia compared to RCD.
Methods: We conducted a retrospective, monocentric study from January 2010 to January 2018 to assess the efficacy and safety of the BR regimen. Twenty-six patients (pts) ≥18 years were analyzed and 23 of them had previously been treated including 13 pts who received the RCD regimen (Rituximab+Cyclophosphomide+Dexamethasone). BR regimen consisted in 375 mg/m2 of rituximab on day 1 and 90 mg/m2 of Bendamustine on days 1 and 2 every 4 weeks, with a maximum of 6 cycles. All patients were considered for response as well as short and long-term complications. Only pts who received BR as salvage treatment were analyzed for survival.
Results: Median age at initiation of BR was 68 (54-84) and 16 pts (62%) were male. At BR initiation, patients were classified according to the IPSS-WM score as low (16%) intermediate (42%) and high risk (42%). Treatment criteria for BR therapy were anemia (42%), high tumor burden (30%), thrombocytopenia (19%), B-symptoms (11%), hyper viscosity (7%), neuropathy (3%), and renal failure (3%). Twenty two (84%) patients completed the planned 6 courses and 89% of them received the full doses. Four patients had to stop for progressive disease (n=1), toxicity (n=2) and death from multi-organ failure 45 days after the first cycle (n=1). Among patients evaluable for response (n=25), the overall response rate (ORR) was 61% including complete response (CR, 19%) and partial response (PR, 42%). When focusing only on patients who received BR as salvage therapy (n=23), 22 pts were evaluable for response with an ORR of 56% (CR=22%, PR=34%). With a median follow-up of 32 months, median progression free survival (PFS) was 40 months (Fig. 1). Apart from the patient who died early after the first cycle, 3 patients died from progressive disease after 3, 7 and 8 months after the end of treatment. Among patients who received previously RCD, median PFS was 31, 5 months and 23 months for BR and RCD respectively (not statistically significant). Hematologic and gastrointestinal (mainly nausea) toxicities were the most frequent adverse events with 23% grade 3-4 neutropenia, 22% grade 2 febrile neutropenia, 11% grade 3-4 thrombocytopenia and 3% grade 3-4 anemia. Six patients (23%) had grade 1 nausea. Twenty six percent of pts had prolonged lymphopenia and 15% had hypogammaglobulinemia with infectious complications leading to gammaglobulin infusions. Only 1 pts had prolonged neutropenia 6 months after the completion of BR regimen.

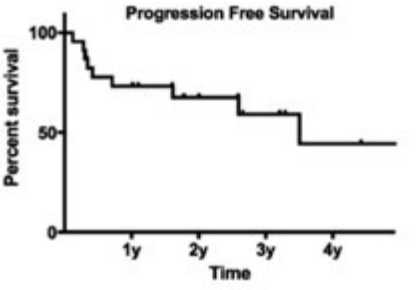

Figure 1.

Summary/Conclusion: BR regimen is efficient in patients previously treated for WM. Although not significant, there is a trend for longer PFS among patients who received previously RCD. BR regimen is well-tolerated even in elderly patients but frequently involved in long-lasting cytopenias which increases the risk of infection and supports prophylactic measures.

PB2031

THE ROLE OF 18F-FDG PET/CT IN THE DIAGNOSIS AND FOLLOW-UP OF GASTRIC LYMPHOMA: A MONOCENTER EXPERIENCE

F. Cacace[1,*], S. Leone[1], M. Memoli[1], C. Mortaruolo[1], N. Pugliese[1], C.G. Mainolfi[2], S. Del Vecchio[2], A. Cuocolo[2], G. Ciancia[2], A. De Renzo[1], M. Picardi[1], F. Pane[1]

[1]Dipartimento ad Attività Integrata di Ematologia, Oncologia, Anatomia Patologica e Diagnostica per Immagini, [2]Dipartimento di Scienze Biomediche Avanzate, AOU Federico II Naples, Naples, Italy

Background: The role of 18F-FDG PET/CT in the diagnosis and follow-up of gastric lymphomas is still controversial. As 18F-FDG PET/CT staging role in gastric DBLC is well established, several studies haven't still clarified the detection rate of PET/CT imaging in gastric MALT lymphomas.
Aims: The aim of our retrospective study is to evaluate the role of 18F-FDG PET/CT in the diagnosis and follow-up of gastric lymphoma.
Methods: Thirty-two patients with histological confirmed gastric lymphoma (MALT: 19; DLBCL: 13) underwent a 18F-FDG PET/CT for initial staging and post therapy evaluation. The PET images were analyzed visually and semi-quantitatively by measuring the maximum standardized uptake value (SUV MAX) and compared with Ann Arbor stage, Lugano staging system for gastrointestinal lymphomas, epidemiological (age, sex), histological /morphological (presence of gastritis, ulcers, H. pylori infection, tumor size, superficial lesions or mass-forming) characteristics.
Results: From January 2007 to November 2016, in our institution, we analyzed 32 gastric lymphoma: 19 patients had histological diagnosis of MALT lymphoma, whereas 13 patients received histological diagnosis of DLBCL. At diagnosis, 15 patients with MALT lymphoma had positive PET/CT-mean lesion SUV max of 6.14 (4.0-18.2) at the corresponding gastric lesion, the remaining 4 were not 18F-FDG avid. Nine patients were H. pylori positive. On the other hand, all 13 patients with DLBCL had positive PET/CT, as expected, with mean lesion SUV max of 17.1 (4-17.1). At post-treatment evaluation, all the patients had histological and radiological complete remission. The overall sensitivity of 18F-FDG PET/CT was 87% (CI 95%: 71-96.5) and specificity 100% (CI 95%: 89.1-100) (p value<0.0001) in our cohort. In MALT lymphoma PET sensitivity was 78% (CI 95%: 54.4-93.5) and specificity 100% (CI 95%: 82.3-100) (p value<0.0001), whereas in DLBCL the sensitivity (CI 95%: 75.3-100) and specificity (CI 95%: 75.3-100) were 100% (p value<0.0001).
Summary/Conclusion: Based on our data, 18F-FDG PET/CT appears to be accurate for initial staging and post treatment follow up in patients with MALT lymphoma and DLBCL. According to our observations, 18F-FDG PET/CT might be used to detect early relapse together with the histological evaluation. Our results should be considered as a preliminary study, limited at our cohort of 32 patients, which will be enlarged with new data.

PB2032

FC RECEPTOR SNP CAN BE A PREDICTOR OF EFFICIENCY OF TARGET THERAPY OF NON-HODGKIN'S MALIGNANT LYMPHOMAS IN RUSSIAN POPULATION

O. Berezina[1,2], T. Pospelova[1,2], F. Maksim[3], V. Ovchinnikov[2,*]

[1]Therapy, hematology and transfusiology, Novosibirsk state medical university, [2]Hematological department, City Clinical Hospital №2, [3]Laboratory of Pharmacogenomics, Institute of Chemical Biology and Fundamental Medicine Siberian Branch of the Russian Academy of Sciences, Novosibirsk, Russian Federation

Background: The effectiveness of targeted therapy of non-Hodgkin's malignant lymphomas with monoclonal antibody (MCA) rituximab has been showed in many randomized clinical trials. Nevertheless, a number of patients have resistance to this class of drugs, which may be associated with the inherent characteristics of the receptor of immune cells. Therefore, it seems relevant to study the genetic polymorphism of Fc -receptors, whose carriage affects this mechanism of action of MCA as an antibody-dependent cellular cytotoxicity.
Aims: To study the impact of Fc receptor SNP (Fc IIIRa) on the results of rituximab therapy in patients with B-cell non-Hodgkin's malignant lymphomas (NHL).
Methods: 191 patients from the City Hematology Center of Novosibirsk with a diagnosis of B-cell NHL were examined. Aggressive lymphomas were verified in 118 patients (61.8%), indolent lymphomas were diagnosed in 73 patients (38.2%). All patients received from 6 to 12 courses of polychemotherapy comprising rituximab. Genotyping of Fc receptor SNP was performed using Taq-man PCR. The significance of the differences was assessed using the $\chi 2$ criterion, the differences at $p<0.05$ were considered statistically significant.
Results: The distribution of the genotypes of the FcIIIRa gene in the aggressive lymphoma group was as follows: 53 patients (45%) have the wild T/T genotype, 57 persons (48.3%) have the T/G genotype, 8 (6.7%) patients have rare G/G genotype. In this group of NHL a complete or partial response to therapy was achieved in 78.6% of patients, relapse or progression of the disease was observed in 21.4% of the patients. During the statistical analysis the effect of this polymorphic locus on the results of therapy with aggressive lymphomas was not detected. In the group with indolent NHL 25 (35.6%) patients have the wild T/T genotype, 34 (46.6%) persons have the T/G genotype, 13 (17,8%) patients have the rare G/G genotype. In this group of NHL complete or partial response to therapy was achieved in 76.7% of patients, relapse or progression of the disease was noted in 23.3% of patients. It was revealed that the "rare" genotype FcγRIIIa was statistically significantly associated with an unfavorable outcome of the disease ($p<0.05$) in patients with indolent variants of NHL. The literature data on the effect of the FcγRIIIa polymorphic locus on the therapy effectiveness of indolent lymphomas are inconsistent, which may be due to genetic heterogeneity of populations and require a meta-analysis in which the results of this study may be included.
Summary/Conclusion: The correlation between the "rare" genotype of the Fc IIIRa polymorphic loci and the treatment failure in the group of patients with indolent lymphomas is shown, which allows considering this SNP as a potential marker of effeciency of treatment with rituximab.

Background: Limited stage (Ann Arbor stage 1 or 2) mantle cell lymphoma (MCL) is an extremely rare disease. Thus, there are little data about the clinical feature and treatment outcomes of patients with early stage mantle cell lymphoma.
Aims: The clinical features were reviewed, and the treatment outcomes were analyzed.
Methods: We consecutively collected stage 1 or 2 MCL cases diagnosed between 2000 and 2016 in 16 institutions in CISL group. All patients were pathologically confirmed and received systemic evaluation for staging work-up.
Results: The median age of patients was 66 years (range: 18-85 years), male (n=31, 75.6%) was predominant compared to female. The majority of patients (n=28, 68.3%) had stage 2 disease, 29 patients (70.7%) were symptomatic. The elevation of LDH (n=2, 4.9%) was not common, thus, 39 patients (95.1%) had low risk (0 or 1 score) of the International Prognostic Index (IPI), and 28 patients (68.3%) had low risk (1-3 score) of the MIPI. As the first therapeutic strategy, most patients (n=37, 90.1%) received chemotherapy, radiotherapy (n=2), surgical resection (n=1), and no treatment (n=1). Of patients who received chemotherapy, 23 patients (56.9%) were administered with rituximab containing regimen, and R-CHOP (n=17) and R-bendamustine (n=4) was commonly used. The best response rate was 97.4% (n=38) including 32 complete response (78%). In aspect of sites of relapse (n=16), local relapse rate was 31.3% (n=5), distant relapse rate 43.8% (n=7), and local & distant relapse rate 25% (n=4). With the median follow-up duration of 40.6 months, the median relapse free survival was 56.1 months, and the 5-year overall survival rate was 80.4%.
Summary/Conclusion: Limited state MCL showed indolent clinical and low risk prognostic features. Chemotherapy could be effective for controlling localized MCL lesion with high complete response rate. Less intensive chemotherapy may be preferred.

PB2034

DUODENAL-TYPE FOLLICULAR LYMPHOMA: WHICH IS THE BEST THERAPEUTIC OPTION?

F. Saraiva[1,*], A. Figueiredo[2], A. Botelho de Sousa[1]

[1]Hematology, HSAC-CHLC, [2]Patology, HCC-CHLC, Lisboa, Portugal

Background: Duodenal-type follicular lymphoma was firstly recognized as a distinct entity in the 2016 revision of the WHO classification. Most cases are asymptomatic, confined to the duodenum, dissemination being very rare and limited to the small bowel. Currently, the best therapeutic approach is unknown, due to its rarity and to the lack of large series. In the few cases that do present symptoms or are at risk of local complications intrinsic to the localization of the tumour (obstruction, haemorrhage, perforation), the option *watch and wait* is unsuitable and the difficulty increases of having to choose among the various options: surgery, radiotherapy, immunotherapy or immunochemotherapy.
Aims: Evaluate if Rituximab in monotherapy is an adequate treatment for patients with duodenal-type follicular lymphoma with symptoms or complications.
Methods: We report 3 cases (patients aged 57, 68 and 74) which were diagnosed due to dyspeptic complaints (2) and by chance (1). All of the patients mentioned were followed from the diagnosis and after treatment until the present day.
Results: Duodenal lesions were described as nodular in 2 cases and extensively ulcerated in the third, measuring from 3.6 to 6 cm. Histologically, all were low-grade (1/2). Two cases presented as isolated duodenal disease and one had biopsy-confirmed ileal involvement. No extra-intestinal involvement was documented. The *watch and wait* approach was deemed inadequate due to the extension and ulceration in one case and the presence of symptoms in the other two. Patients were treated with rituximab in monotherapy. All became asymptomatic (sustained after a 12-month period), and the 6-month endoscopic evaluation showed complete regression of the lesions in 2 of the patients and partial regression in the other (40% reduction).
Summary/Conclusion: Duodenal-type follicular lymphoma is very rare and data regarding treatment options are limited due to the small number of reported cases. Concerning the therapeutic approach, it seems to be a remarkably indolent variant of follicular lymphoma, which may have a *watch and wait* approach in most cases. Nonetheless, although randomized studies are difficult in this rare disorder, when the presentation implies treatment, whether due to the existence of symptoms or to a risk of local complications, immunotherapy with an anti-CD20 antibody is an appropriate option.

PB2035

A RETROSPECTIVE REVIEW OF EXPERIENCE IN DELIVERING MAINTENANCE RITUXIMAB FOR FOLLICULAR LYMPHOMA IN A DISTRICT GENERAL HOSPITAL

A. Pryce*, M. Shah, A. Babb

Haematology Department, West Middlesex University Hospital, London, United Kingdom

Background: The PRIMA study findings support the benefit of 2-years of Rituximab maintenance in patients with follicular lymphoma (FL) responding to immuno-chemotherapy treatment, with maintenance Rituximab delivering a sustained and persistent benefit with improved progression free survival without an unacceptable increase in long term toxicity. Therefore it is now routine practice to offer 2 years of maintenance Rituximab to this group of patients.
Aims: We reviewed our experience of rituximab maintenance in a district general hospital looking particularly at rate of infections and development of complications and toxicities.
Methods: Between January 2011 and January 2018 52 patients completed 2 years of Rituximab maintenance for Follicular lymphoma. We conducted a retrospective case note review, accessing clinical notes, laboratory results and radiological imaging to review for development of immunodeficiency, infection rates, and respiratory complications.
Results: The primary immuno-chemotherapy most frequently used prior to commencing maintenance was R-CHOP (42.3%). Maintenance Rituximab was planned for 24 months. Infective complications were common with patients receiving on average 2 courses of antibiotics during the maintenance period. Admissions were relatively frequent with 59.6% of patients requiring at least one admission, and 9.6% requiring three of more admissions, with infection being the most common reason for admission. During the maintenance Rituximab period 30.8% of the patients developed neutropenia and 28.8% developed significant hypogammaglobulinemia. 50% reported chest symptoms and 30.8% had new radiological findings of lung disease on CT compared with their end of treatment CT chest before commencing the Rituximab maintenance. Most common changes were atelectasis, but 11.5% developed new ground glass opacities or interlobular thickening, and 2% developed new diagnosis of bronchiectasis. One patient reactivated pulmonary tuberculosis. 3.8% of patients needed to discontinue treatment due to the frequency of respiratory tract symptoms.
Summary/Conclusion: This experience from treating patients at a district general hospital highlights that as maintenance Rituximab is increasing being offered due to it's beneficial affect on progression free survival, we need to be vigilant to the infective and respiratory complications that can develop. Therefore it is imperative that in order to reduce these complications and not adversely impact on the patients quality of life steps should be taken to monitor carefully for development of neutropenia, hypogammoglobulinemia, or chest symptoms or signs in order to take early interventions such as administration of G-CSF or monthly IVIg, and consideration of early imaging to prevent infectious and respiratory complications.

PB2036

HAIRY CELL LEUKAEMIA-SURVIVAL ANALYSIS AND PROGNOSTIC FACTORS-UNICENTRIC EXPERIENCE

D. Mota*, A. Roque, M. Santos, J.P. Carda, M.L. Ribeiro

Hematology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Hairy cell leukaemia (HCL) is a rare condition characterized by pancytopenia and markedly susceptibility to infections. This lymphoproliferative disease presents high rates of response and survival. Nevertheless, treatment may not be curative, and there may be a need for re-treatment at the time of relapse. Thus, the identification of patients at risk of treatment failure remains an important question.
Aims: Characterization of the population with HCL diagnosed in a tertiary hospital. To identify in this group of patients factors predictors of survival.
Methods: Retrospective analysis of patients diagnosed with HCL at our institution between January, 1988 and December, 2017.
Results: Were included 51 patients; male gender 80.4% (n=41); median age at diagnosis 57 years (35-83). Had comorbidities 56.9% (n=29). Splenomegaly was present in 68% (n=34) and B symptoms in 33.3% (n=17). Had haemoglobin <11 g/dL 39.2% (n=20), platelets <100 G/L 58.8% (n=30), neutrophils<1G/L 58% (n=29). Median follow-up was 78.8 months (0.6-290.8). First line treatment was cladribine in 77.6% (n=38), pentostatin in 4% (n=2) and IFNα in 18.4% (n=9), remission (CR+PR) was obtained in 87.8% (n=43). Use of cladribine was associated with greater achievement of complete response (79.0 *vs* 22.2%, OR 0.28; p=0.004). Were re-treated 22 patients-72.7% of them with purine analogues (PA) –, 81.8% obtaining remission (CR+PR). Median overall survival (OS) was 232.8 months (232.7 with cladribine, 287.3 with IFNα). Median progression free survival (PFS) was 71.2 months (102.7 with cladribine, 67 with IFNα). Although there were no differences in OS between cladribine and IFNα (p=0.6892), in PFS there were significative differences (p=0.045). Seven patients presented second neoplasia, all of them treated with PA. Of the 51 patients, 27.5% died, 28.6% of them of infection. OS was inferior in age>65 years (p<0.001), ECOG >0 (p=0.0053) and serious infection at diagnosis (p=0.012). After multivariate analysis, age>65 years (HR 41.95; p=0.002) and ECOG>0 (HR 6.19; p=0.008) were independent predictors of lower survival at diagnosis.
Summary/Conclusion: Although the PA contributed to increase of complete response rate and PFS, there is still a need to optimize therapeutic strategies in order to increase OS, as decreasing adverse events and relapse / refractoriness in patients with HCL. Factors such as age at diagnosis >65 years and ECOG >0 are predictors of lower survival, however, more robust studies are needed to validate and identify other potential prognostic factors.

PB2037

SINGLE-CENTER EXPERIENCE WITH BENDAMUSTINE-BASED IMMUNOCHEMOTERAPY REGIMENS IN INDOLENT LYMPHOID MALIGNANCIES AND MANTLE-CELL LYMPHOMA

B. Dreta[1,*], S. Bašić-Kinda[1], D. Dujmović[2], I. Radman[1], M. Vodanović[1], P. Rončević[1], S. Dotlić[3], K. Dubravčić[4], M. Kralik[5], I. Aurer[1]

[1]Division of Hematology, Department of Internal Medicine, University Hospital Centre Zagreb, [2]Medical School, University of Zagreb, [3]Department of Pathology and Cytology, [4]Department of Laboratory Diagnostics, [5]Department of Radiology, University Hospital Centre Zagreb, Zagreb, Croatia

Background: Bendamustine-based regimens belong to most effective treatments for indolent lymphoid malignancies but reports on its toxicities vary.
Aims: To compare efficacy and toxicity of bendamustine-based regimens in a real-world situation to those reported in the literature and to identify possible risk factors for development of complications.
Methods: We performed a retrospective chart review of all our patients with CLL, indolent NHLs (iNHL) and mantle cell lymphoma (MCL) treated with bendamustine-based regimens between 2013 and 2017.
Results: 123 patients, 36-88 (median 67) years old, were included in this analysis. 65 were male and 58 female. 51 were younger than 65 y and 19 older than 75 y. 35 had chronic lymphocytic leukemia (CLL), 35 follicular lymphoma (FL), 19 marginal zone lymphoma (MZL), 14 lymphoplasmocytic lymphoma (LPL) and 20 MCL. 63 were treated in 1st, 42 in 2nd and 18 patients in subsequent lines of treatment. 103 patients received BR or similar, 19 R-BAC and 1 bendamustine monotherapy. Median follow-up was 14 mo. Response rates (RR), progression-free survival (PFS) and overall survival were similar to those reported in seminal studies. RR in 1 st line was 87% for CLL, 93% for indolent NHL (iNHL) and 80% for MCL. In later lines RR was 85%, 72% and 67% respectively. 18-mo PFS was 83% in 1st line CLL and 91% in iNHL, and 77% and 68% respectively in 2nd line. Hematological toxicity was also similar to that reported; in 1st line gr 3-4 neutropenia occurred in 20%, thrombocytopenia in 8% and anemia in 8% of patients. In later treatment lines gr 3-4 neutropenia occurred in 30%, thrombocytopenia in 11% and anemia in 10% of patients. Skin changes were mild, serious gastrointestinal toxicity occurred in 3% of patients. Infections were substantially more frequent than reported in the NHL1 and NHL2 studies, but not in CLL10. In 1st line of treatment gr 1-2 infections occurred in 38% and gr 3-4 in 22% of patients, and in later treatment lines in 30% and 30% respectively. Risk of serious infections was significantly higher in pts. previously treated with ≥2 lines (50% *vs* 23%, p=0,02) and those with reduced IgG levels at end of treatment (36% *vs* 14%, p=0.015). Risk of infections of all grades was higher in those with IgG<4 g/L (82% *vs* 59%, p=0.018); there was a trend in pts older than 75 (79% *vs* 57%, p=0.076). Sex, disease type, initial IgG levels and antimicrobial prophylaxis did not significantly influence infection risk. 5 1st line pts died of toxicity and 2 of lymphoma in comparison to 7 and 6 in later treatment lines. Infections clustered during first two cycles and after end of therapy. Four pts. developed secondary malignancies.
Summary/Conclusion: Efficacy of bendamustine-based regimens in routine clinical practice is similar to that reported in randomized studies, but infections are more frequent. Low IgG levels, advanced age and having received more than 2 lines of therapy increase the risk. Increased risk persists after end of therapy.

PB2038

HAIRY CELL LEUKEMIA: 20-YEAR SINGLE CENTER EXPERIENCE

M. Criscuolo*, L. Fianchi, E. Galli, C. Rotolo, F. D'Alò, L. Laurenti, A. Bacigalupo, L. Pagano

Hematology, Catholic University of Sacred Heart Fondazione Policlinico Universitario A. Gemelli, Rome, Italy

Background: Hairy cell leukemia (HCL) is a rare indolent disease which is curable in most cases. However, a small number of patients is still expected to relapse, or die, mainly due to infective complications.
Aims: The aim of the study is to analyze the course of the disease in a population of uniformly treated patients and identify early and late adverse events during a 20-year follow-up.
Methods: We retrospectively reviewed the charts and collected clinical and laboratory data of 37 patients diagnosed with HCL from October 1997 through May 2017. They were all treated with one course of Cladribine as first line therapy at our Hematology Department. Particularly, we focused on infective events, allergy, secondary neoplasms and relapse during the follow-up.
Results: Most patients sought medical evaluation because of constitutional symptoms and emerging abdominal discomfort. At disease onset, two-third of patients presented with white blood cells count lower than $4x10^9$/L and platelets count lower than $100x10^9$/L; massive splenomegaly was detected in 50% of patients. The median time to treatment was 1.4 months (range 0.2-20.6 months): cladribine were administered as a 7-day continue infusion in 89% of patients. The overall response rate was 97%, with 92% complete and 5% partial remissions. During neutropenia, 16 out of 23 patients (69.5%) experienced at least one infectious episode: one patients died, probably due to invasive aspergillosis, 2.7 months after treatment with no sign of hematologic recovery. Median time to recovery of neutropenia was 23 days (range: 5-720 days). Eight patients (22%) reported a diffuse cutaneous allergic reaction: all recovered after few days of antihistamine and steroid administration. Seven patients (19%) experienced a relapse, after a median time of 51.2 months (range: 17.3-146.1 months): 4 were retreated with Cladribine, 1 with Cladribine and Rituximab, 1 with Interferon α and 1 refused treatment. The overall response rate was 57.1% (4 patients, 2 complete and 2 partial responses); 1 patient died two weeks after treatment due to sepsis and 1 was treated with Pentostatin after failure of Interferon α. This patient experienced another relapse 2 years later, and died of septic shock 14 days after starting a BRAF inhibitor. After a median follow-up of 50.6 months (range: 3-219.5 months), overall mortality was 13%: 3 patients died from infection during neutropenia related to chemotherapy, and 2 patients died of causes unrelated to treatment (1 following a myocardial infarction and 1 from senescence). Overall survival and disease-free survival at 20 years were 78% and 81% respectively. Incidence of secondary neoplasms was 2.7%: one patient developed breast cancer 5 years after HCL onset. Age, white blood cells count, bone marrow fibrosis, splenomegaly, infections, allergy, duration of neutropenia and time to best response did not show any statistical significance for mortality at univariate analysis.
Summary/Conclusion: Due to the rarity of disease, multicentric survey is needed to identify factors predictive of response to treatment and ultimately survival. The patients who experienced a fatal infection during prolonged grade 4 neutropenia are of concern: reducing the duration of neutropenia using lower grade immunosuppressive and myelotoxic drugs, should be tested in order to improve the life expectancy of these patients.

PB2039

GASTRIC MALT LYMPHOMA : A MONOCENTRIC STUDY

M. Medhaffar[1,*], L. chtourou[2], I. Frikha[1], A. Amouri[2], M. Elloumi[1], N. Tahri[2]

[1]Clinical Hematology, [2]Gastro Enterology, Hedi Cahker hospital Sfax University, Sfax, Tunisia

Background: Gastric MALT lymphoma is one of low grade B lymphoma that can be cured in many cases by antibiotics targeting HP infection.
Aims: We report a study of 35 patients diagnosed and treated for Gastric MALT lymphoma.
Methods: This study concern all patients followed for Gastric MALT lymphoma between 2001 and 2016 at Sfax Hedi Chaker Hospital in the south of Tunisia. Upper endoscopy was performed for all patients, multiple biopsies served to Histo-pathologic analysis and HP detection. Physical examination, LDH dosage, echo-endoscopy, chest and abdominal scan and bone marrow biopsy were performed to Musshoff (Ann-Arbor modified) staging of lymphoma.First line treatment consists on HP eradication therapy (patrician choice: three therapy, sequential therapy or quadri-therapy Bismuth). A double endoscopic control was performed initially to verify HP eradication, and secondary to evaluate lymphoma response according to the GELA-Lysa criteria.Stomach Radiotherapy was proposed for HP negative localized lymphoma, HP resistant to two different eradication schemas or no responded lymphoma.
Results: A total of 35 patients had Gastric MALT lymphoma. Median of age was 51 years. Sex ratio=0.94. Pseudo-gastritis, ulcers, and pseudotumoral aspects were found in respectively 40%, 35% and 25%. HP was found in 32 patients (91%). Lymphoma had localized stage in all patients (stage IE= 80%, stage IIE=20%). 32 HP positive and 2 HP negative patients received first line eradication therapy. Eradication was obtained in 68% of cases and in all HP positive cases (100%) after two switched schemas. According to GELA-Lysa criteria: complete response was obtained in 27 cases (CR=25, pMRD=2), partial response in three cases, AND no change response in four cases. Five patients (2HP negative and 3 HP positive) underwent Radiotherapy achieving a CR. During follow up, no patient have lymphoma relapse, two cases with NC response showed a progression to diffuse B large cell lymphoma.
Summary/Conclusion: In our region, Gastric MALT lymphoma is frequently associated to HP (more than 90%) and presenting in localized stage. Eradication schemas therapy leads to the disappearance of HP in 100% of cases and regression of lymphoma in 80% of cases even in HP negative patients. Radiotherapy stills a second arm for non responded patients.

PB2040

CONTRIBUTION OF FLOW CYTOMETRY BY FINE NEEDLE ASPIRATION COUPLED WITH CYTOLOGY IN THE DIAGNOSIS AND CLASSIFICATION OF SMALL-CELL NHL B AND ITS CORRELATION WITH HISTOLOGY AND IMMUNOHISTOCHEMISTRY

A. Mohamed Rafik*, A. Fatima Zohra, B. Salah Eddine

Hématology, HCA, Dr Mohamed Seghir Nekkache, Alger, Algeria

Background: In the new WHO 2016 classification of lymphomas, the relative importance of each of the morphological, immunophenotypic, genetic and clinical criteria varies from one lymphoma to another, but the morphological and immunophenotypic criteria remain the cornerstone of the diagnosis. As a result, cytology and CMF coupling by fine needle aspiration puncture are easy and valuable tools for the diagnosis and follow-up of lymphoproliferative disorders, especially small-cell NHL-B-cells.
Aims: To demonstrate the value of fine needle aspiration coupled with CMF for rapid outpatient diagnosis and follow-up of small-cell NHL B.
Methods: Retrospective and descriptive study over a period of 6 years (from January 2010 to December 2015). We collected 180 samples including 134 evaluable. The diagnosis of small cell lymphoma was made in 38 patients (28%), 33 lymphadenopathies (by fine needle aspiration (23 G)), 3 ascites fluid, 1 pleural fluid and 1 subcutaneous mass. skin. A cytological study (MGG) was performed on the various samples. Labeling with more than 10 Antibodies on average for each sample. Then we proceed to the acquisition and analysis by flow cytometry (FACS CALIBUR 3 colors of Becton Dickinson). The histological study with immunohistochemistry was performed in 33 patients: 21 biopsies of adenopathy (14 biopsies of ADP alone, 6 with PBO, 1 cutaneous biopsy), 2 PBO alone, 1 tonsillectomy, 1 transparietal biopsy associated with a PBO, 1 exeresis biopsy of a hepatic mass and 1 gastrectomy. The 5 unexplained biopsies for the following reasons: 3 cases of ascites whose biopsy is difficult and 2 cases of relapse.
Results: In our series, the average age of patients was 61 years (22-83 years), with a clear male predominance (26 men and 12 women, sex ratio 2.5). At the CMF, several diagnoses and types of NHL could be made: follicular NHL 10 cases (26%), NHL with small cell without being able to specify the exact type 9 cases (24%), lymphocytic NHL 8 cases (21%), NHL to coat cells 7 cases (18%), NHL marginal area 2 cases (5%), lymphoplasmocytic NHL 2 cases (5%). In the histology, the diagnostics performed in 33 patients are as follows: 3 cases of LGCDB (41%), small cell NHL 5 cases (8%), follicular NHL 8 cases (7%), NHL with mantle cells 6 case (5%), marginal zone NHL 1 case (5%), lymphocytic NHL 7 cases (2%), angioimmunoblastic NHL 1 case (4%), inflammatory (reactive) 2 cases (5%). After these results, the overall correlation between CMF and histology is 94% in the diagnosis of NHL B: 70% the CMF allowed to make the diagnosis and to type the NHL, in 24% one finds a concordance in the diagnosis without being able to specify the morphological type and 6% of discordance (2 false positives in CMF).
Summary/Conclusion: when the fine needle aspiration coupled with CMF is performed by experienced operators and for the correct indications, it is one of the safest technique of small cell NHL B diagnostic and less massive, more profitable and more accurate.

Infectious diseases, supportive care

IMATINIB MESYLATE ON PREVALENCE OF FALCIPARUM MALARIA: A CASE CONTROL STUDY FROM A TERTIARY CARE CENTRE IN KOLKATA

A. Iqbal[1,*], J. Chakraborty[1], S. Choudhuri[1], A. Naik[2], M. Bhattacharyya[1]

[1]Clinical Hematology, Institute of Haematology and Transfusion Medicine, [2]Transfusion Medicine, Medical College and Hospital, Kolkata, India

Background: Rising evidence of artemisin resistant malaria in Indian subcontinent and South America has prompted researchers to search for alternative antimalarials. In the last few decades, few reports and subsequent *in vitro* results have emerged showing dependence of malarial parasites, particularly Pl. falciparum on RBC tyrosine kinases for its maturation and egress. As there were no clinical data to support the hypothesis, we conducted a case control study with patients of CML-CP on fixed dose Imatinib as cases and a representative healthy population as control.
Aims: To find the prevalence of asymptomatic malarial parasitemia in patients of CML-CP on Imatinib and compare with the prevalence in healthy blood donors. To internally validate the results of positive RDT samples with PCR in both cases and controls.
Methods: A standard questionnaire and Rapid Diagnostic Test (RDT) for plasmodium antigens from the blood of cases attending CML clinic were used as study tools. 191 CML patients on Imatinib 400mg/d for a minimum period of 1 year were analysed.
Results: Out of 54 febrile episodes during the study period, one patient had vivax malaria. RDT testing on non-febrile participants revealed two samples positive for dual vivax-falciparum antigens and the other two for vivax antigen. All positive results were internally validated with PCR using two species-specific forward primers which showed three cases positive for vivax and one positive for both vivax and falciparum. Among 205 controls selected from healthy voluntary blood donors, three had vivax infections, three had falciparum infections and four were found to have infections with both parasites. The prevalence of malarial infections in cases and controls were found to be 2.05% and 4.87% respectively while falciparum parasitemia in cases and controls were found to be 0.51% and 3.41% respectively. When analysed, the difference was found to be statistically significant.
Summary/Conclusion: In a malaria endemic region where asymptomatic parasitemia rates are high, imatinib mesylate given as a fixed daily dose provided protection to patients of CML-CP from falciparum malaria. However the association between the occurrence of vivax malaria and exposure to Imatinib was not statistically significant. The internal validation of positive samples by PCR showed a high, acceptable correlation.

PB2042

RESISTANCE OF THE HEPATITIS B VIRUS IN PATIENTS WITH LYMPHOMAS

S. Lepkov[1,*], I. Subortceva[2], E. Demina[3], G. Tumian[3], J. Ribuchina[3], O. Kolomeitsev[3], P. Zeynalova[3], I. Komarov[3], A. Semenova[3], N. Kokosadze[3], S. Borisovskay[4], T. Padjeva[4], R. [1]Therapy, National Research Medical University named by N.I. Pirogov, [2]Haematology, National Medical Research Center for Hematology, [3]Oncology, N.N. Blokhin National Cancer Research Center, [4]Therapy, [5]Radiology, City Clinical Hospital. V.M. Buyanova, [6]Haematology, Hematologic Moscow City Center at the State Clinical Hospital named by S. Botkin., moscow, Russian Federation

Background: Reactivation of the hepatitis B virus (HBV) is a serious, and in some cases life-threatening, complication that occurs in patients receiving chemotherapy. Conducting target therapy (rituximab) in mono-regime or in combination with polychemotherapy (PCT) is a factor of high risk of reactivation of HBV. Patients with resolved HBV infection who have a hepatitis B surface antigen (HBsAg) in their blood have a HBV reactivity in more then 80%, and fatal liver failure is not unusual for this category of patients.
Aims: In study included 53 patients with malignant lymphomas who had reactivated HBV from 2002 to 2016 during the treatment of lymphoma. Male: female ratio was 1: 1. The age of the patients ranged from 19 to 82 years (median 35 years). Among patients there were 11 with Hodgkin's lymphoma(HL) and 42 non-Hodgkin's lymphoma(NHL) (18 with indolent and 24 with aggressive). Reactivation of HBV in 89% (47) patients developed after 4-6 courses. In 6 patients, the reactivation of HBV developed after the end of PCT for 3 months. In patients who had reactivation HBV the ALT level was from 90 to 600 IU/L, AST-70 to 560 UD/L, alkaline phosphatase ranged from 120 to 1700 UD/L, GGTP-from 88 to 960 IU/L. The level of HBV DNA was from $1x10^5$ to $1.6x10^9$ copies/ml.
Methods: All patients with HBV reactivation were prescribed antiviral therapy: 37 patients received lamivudine for 100 mg/day and 15-entecavir for 1 mg/day. In 70% (37) patients on antiviral therapy, complete remission of HBV was achieved. In 30% (15) patients, the level of enzymes decreased and was not higher than 2xUIN. However, the level of HBV DNA was from $3x10^3$ to $1x10^5$ copies/ml. Antiviral therapy changed to tenofavir 300 mg per day in all 15 patients. Complete remission was achieved in 11 patients. 4 patients (3 with NHL and 1 with HL) had a short period (3-5 month) of decreasing HBV DNA, then HBV DNA began to rise again. The level of HBV DNA was $1x10^5$- $1.4x10^7$copies/ml. The resistance of HBV to the therapy of tenofavir was verify.
Results: 3 patients with NHL received the therapy with alpha interferon. The remission was achieved in 2 patients on therapy with tenofavir+interferon. In 1 patient, the level of HBV DNA was $1x10^2$ copies/ml. In patient with HL and resistant HBV infection developed the relapse of the HL. The patient, according to vital indications, started PCT. After 2 courses of PCT complications with multi-organ disturbances developed and the patient died.
Summary/Conclusion: Therapy of reactivation of HBV in patients with lymphomas is very complex. This problem has not been resolved. We surmise new mutant forms of HBV infection. Chemotherapy may leads the mutations in the genome of the hepatitis B virus. Therapy of new identified mutant forms requires the creation of new molecules. At present, when a multiple resistance of virus B occurs to atypical nucleosides, the main drug in the treatment of this hepatitis B is only alpha interferon

PB2043

PRIMARY PROPHYLAXIS OF INVASIVE FUNGAL INFECTIONS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA: RESULTS FROM A SINGLE-CENTRE STUDY

N.S. Fracchiolla[1,*], M. Sciumè[1], F. Cavalca[1], N. Orofino[1], F. Guidotti[1], A. Grancini[2], A. Freyrie[1], M.C. Goldaniga[1], D. Consonni[3], A. Cortelezzi[1]

[1]Oncohematology Division, IRCCS Ca' Granda-Maggiore Policlinico Hospital Foundation and University of Milan, [2]UOS Microbiology, Central Laboratory, I.R.C.C.S. Foundation, Cà Granda Ospedale Maggiore Policlinico, [3]Unit of Epidemiology, Fondazione IRCCS Ca' Granda-Ospedale Maggiore Policlinico, Milan, Italy

Background: Immunocompromised patients (pts) are at high risk of invasive fungal infections (IFIs), in particular those affected by acute myeloid leukemia (AML) undergoing remission-induction chemotherapy. Posaconazole (PSZ) is now available in different formulations and its use as antifungal prophylaxis in this high-risk hematological pts is strongly recommended.
Aims: Our aim was to describe the efficacy of primary prophylaxis of IFIs with PSZ in a real-life cohort of AML pts during induction chemotherapy.
Methods: AML pts consecutively treated with remission-induction chemotherapy (up to 3rd line treatment) between January 2010 and July 2017 were selected from institutional database. We excluded acute promyelocytic leukemia, re-induction therapy performed for relapse after transplantation and patients treated with hypomethylating agent. Diagnosis of IFIs was carried out according to the revised European Organization for Research and Treatment of Cancer/Mycoses Study Group (EORTC/MSG) definitions published in 2008.
Results: We identified 123 AML pts who received 171 remission-induction treatments. Primary prophylaxis of IFIs with PSZ was made in 110 cases, while the remaining 61 cases did not received any systemic antifungal prophylaxis. Among patients who received PSZ, median age was 61 years (male/female ratio 64/34%), in the remaining population median age was 64 years (male/female ratio 49/51%). Seventy cases were first-line induction therapies, while 40 were re-induction treatments. PSZ was given as oral suspension in 104 cases; the tablet formulation has been introduced since 2017 and it was used in 6 cases. Over 90% of analysed cases developed a febrile event. An antifungal treatment was administered in 28 of 61 cases (46%) which did not received prophylaxis and in 26 (23%) cases which received PSZ (p=0.003). Thirty-five (57%) cases in no prophylaxis group and 45 (41%) among PSZ group underwent a chest CT scan (p=0.039). CT alterations suggestive for IFIs were found in 71% of no PSZ cases and in 42% of PSZ cases with a statistically significant difference (p<0,01). Serum galactomannan antigen was positive in 3% of the tested cases: 1 of 106 PSZ tested cases and 4 out of 58 no PSZ tested cases (p<0,01). Yeasts and moulds were identified respectively in 5 (8%) of patients who didn't

received an antifungal prophylaxis; all microorganisms were isolated from the respiratory tract, except for one liver mould and one yeast positivity on rectal swab. Seven (6%) PSZ patients had a positivity for yeasts, in the same group 3 (3%) patients were positive for moulds (p=0.04). The latter were isolated from the respiratory tract, while almost the whole yeasts from blood samples. Seven (4%) cases were classified as proven (2 no PSZ group, 5 PSZ group), 12 (7%) as probable (9 no PSZ group, 3 PSZ group) and 24 (15 no PSZ group, 9 PSZ group) as possible IFIs. Eleven (6%) cases could not be classified (2 no PSZ, 9 PSZ). The total number of death was 14 (8%). Among patients who received an antifungal treatment, 9 deaths were observed (3 PSZ group, 6 no PSZ group). In the prophylaxed group, the most used antifungal treatment was liposomal amphotericin B (77%), followed by voriconazole (15%); while among no PSZ cases voriconazole was used in about 50% of patients (p<0.001). Twenty-one cases received a sequential or a combination regimen.
Summary/Conclusion: This monocentric survey underlined the feasibility and efficacy of PSZ prophylaxis in clinical practice; PSZ use confirm to be associated to lower incidence of IFIs, less need for antifungal treatment and lower IFIs attributable mortality.

PB2044

LOW FREQUENCY OF PRIMARY PROPHYLACTIC USE OF G-CSF IN THE JSMO FEBRILE NEUTROPENIA GUIDELINES BY JAPANESE ONCOLOGISTS TREATING PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA USING R-CHOP THERAPY

I. Yoshida[1,*], K. Tamura[2], S.-I. Kimura[3], H. Fujita[4], H. Iwasaki[5], S. Yano[6], H. Kusaba[7], K. Takahashi[8], T. Okamura[9], M. Yoshida[10]

[1]Hematologic oncology, National Hospital Organization Shikoku Cancer Center, Matsuyama, [2]General Medical Research Center, Fukuoka University, Fukuoka, [3]Hematology, Saitama Medical Center, Saitama, [4]Hematology, Saiseikai Yokohama Nanbu Hospital, Yokohama, [5]Infection Control and Prevention, University of Fukui, Faculty of Medical Sciences, Fukui, [6]Clinical Oncology and Hematology, Jikei University School of Medicine, Tokyo, [7]Medicine and Biosystemic Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, [8]Respiratory Medicine, Aichi Cancer Center Aichi Hospital, Okazaki, [9] Breast and Endocrine Surgery, Tokai University School of Medicine, Isehara, [10]Fourth Department of Internal Medicine, Teikyo University School of Medicine, Kawasaki, Japan

Background: Maintenance of dose intensity in patients with a potentially curable disease, such as diffuse large B-cell lymphoma (DLBCL), who are treated with chemotherapy, such as R-CHOP (rituximab, doxorubicin, cyclophosphamide, vincristine, prednisolone), is very important. We conducted a nationwide questionnaire survey to see how DLBCL patients are treated by Japanese oncologists, and reported a part of the findings at the 15th Japanese Society of Medical Oncology (JSMO) annual meeting (Kobe, 2017), showing that the dose of R-CHOP therapy was easily reduced (<65 years old: 16.4%; ≥65 years old: 44.3%). One of the reasons for dose reduction was bone marrow suppression and febrile neutropenia (FN). The results of further analysis of FN are reported here in detail.
Aims: To survey Japanese real-world FN treatment and the prophylactic use of granulocyte-colony stimulating factor (G-CSF), oral anti-bacterials, anti-fungals, drugs against herpes simplex, and sulfamethoxazole-trimethoprim during curative treatment using R-CHOP therapy for patients with DLBCL.
Methods: The FN Study Group of the Japanese Association of Supportive Care in Cancer (JASCC) designed a questionnaire on FN during R-CHOP therapy, which consists of 65 questions addressing the management of DLBCL in different practice settings. The survey was conducted from July 25 to August 22, 2016. JSMO members were requested to answer the questions on an online survey (SurveyMonkey.com), and the results were collected and analyzed.
Results: The survey was answered by 336 (4%) of the 8,158 JSMO members. Accordingly, 93.1% and 54.7% of respondents said they would take blood cultures before the start of anti-bacterial agents for inpatients and outpatients, respectively. Primary G-CSF prophylaxis among the non-elderly (<65 years old) is used by 23.6% of respondents to prevent FN in inpatients and by 26.8% for outpatients. It is routinely used for elderly (≥65 years old) patients by 39.9% of respondents for inpatients and by 45.3% for outpatients. The most commonly used antimicrobials for FN at outpatient clinics are oral new quinolones (66.8%), while inpatient FN is treated using intravenous infusion of 3rd generation or 4th generation cephalosporins (76.8%). Prophylactic use of oral anti-bacterials, anti-fungals, drugs against herpes simplex, and sulfamethoxazole-trimethoprim to prevent development of FN, herpes simplex infection, and Pneumocystis jirovecii pneumonia was reported by 12.2%, 18.2%, 3.7%, and 67.7% of the respondents, respectively. Only 10.2% of respondents use Multinational Association of Supportive Care in Cancer score as a reference to estimate FN risk, while 93.7% of them are fully aware of JSMO FN guidelines and 73.2% of them treat FN patients accordingly.
Summary/Conclusion: Although the respondents' rate of adherence to the JSMO FN guidelines for treatment of FN is relatively high, primary prophylactic use of G-CSF is low, especially for elderly (≥65 years old) patients. It is suggested that appropriate G-CSF use would substantially reduce FN further, allowing maintenance of relative dose intensity of R-CHOP therapy and improving the treatment outcomes of patients with DLBCL.

PB2045

PURPLE URINE BAG SYNDROME IN TWO ELDERLY WOMEN WITH ACUTE MYELOID LEUKAEMIA

C. Moret[1,*], R. Coll[1], D. Cruz[1], C. Babià[2], R. Guàrdia[1], J.N. Kelleher[1], M. Sagüés[1], Y. Gonzalez[1], J.M. Roncero[1], N.Y. Santos[1], D. Gallardo[1]

[1]Hematology and hemotherapy, ICO Girona, [2]Palliative Care Unit, Hospital de Santa Caterina, GIRONA, Spain

Background: Purple urine bag syndrome (PUBS) is a rare disorder characterized by purple discoloration of urine inside the urine collection bag and tube. It's usually seen in elderly women with a history of chronic or acute renal failure and constipation during longterm urinary catheterisation. Recognition of this entity is important to minimize concern and distress for patients and their relatives and also to avoid overmanagement.
Aims: CASE 1. An 86 year old woman was hospitalized because of anorexia, fever and asthenia. Her past medical history included arterial hypertension and chronic constipation. Basic investigations were done Hb 91 g/L, platelet count $18x10^9$/L and leucocytes 41.6 K/mcL. The bone marrow smear was compatible with Acute Myelomonocytic Leukaemia (AML) with negative cytogenetic and molecular biology. Due to the elderly conditions of the patient, palliative support treatment was decided.After 72 hours she presented lower abdominal pain with acute urinary retention and a urinary catheter was introduced. During the hospitalization, a purple discoloration of the urine bag and tube was noted. Urine examination showed urine leucocytes without RBC's with multi sensitive *E.Coli* on the urine culture. She was started on parenteral Ciprofloxacin and the catheter was changed, the purple urine returned to its normal colour but she died 48 hours later. **CASE 2.** An 88 year old woman was admitted to the Palliative Care Unit because of fever and dysuria in the context of neutropenia grade IV and severe constipation during the preceding days. Her past medical history included AML with normal karyotype and high rated FLT3-ITD diagnosed 6 months apreviously. She was receiving palliative support due to her age. On admission, she was found to have bleeding diathesis and acute urinary retention. Pansensitive *E.Coli* was isolated from blood and urine cultures. She was treated with intravenous Ciprofloxacin, urine catheterisation and laxatives. 48 hours later, she developed severe sepsis with hemodynamic instability and refractory hypotension. The urine in the bag was strikingly purple in colour. Because of the refractory sepsis condition and a terminal AML diagnosis,finally died 72 hrs after admission.
Methods: PUBS is a rare phenomenon where urine in catheter bags and tubing turns purple. The prevalence is unknown, range estimate between 8.3% and 42.1%.

Figure 1.

Results: PUBS occurs when the pigments indigo and indirubin, products of bacterial sulphatase and phosphatase mediated tryptophan metabolism,

accumulate in the urine and cross react with the PVC of catheter tubing to produce a purple hue. These bacteria include *Providencia spp, Citrobacter spp, Klebsiella pneumoniae,Proteus spp, Escherichia coli, Enterococcus spp, Morganella morganii, Pseudomonas aeruginosa* and B Streptococci. The principal PUBS risk factors include elderly patients, renal disease, chronic catheterisation, dehydratation, severe constipation, increased dietary thryptophan, high urinary bacterial load and urine alkalinity. There are several causes that change the urine colour:food dyes, drugs,haematuria, myoglobinuria, nephrolithiasis and poisons so it's important to consider some details from history to avoid unnecessary diagnostic tests. PUBS presentation is generally benign, but is associated with high morbidity and mortality due to the backgrounds of the patients. The management involve regular changing of urinary catheters,antibiotics if UTI is demonstrated and laxatives.
Summary/Conclusion: In the two cases described,the diagnosis was not controversial because urinalysis,urine and blood culture were positive.

PB2046

HHV6 REACTIVATION AFTER AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION IS MANAGEABLE WITH IMMUNO GLOBULIN TREATMENT A SINGLE CENTER STUDY

S. Desilets, L. Gilis, S. Assaad, Y. Guillermin, P. Rey, M. Michallet, A. Belhabri, A.-S. Michallet*, L. Lebras, E. Nicolas-Virelizier

Hematology, Centre Léon Bérard, Lyon, France

Background: HHV6 reactivation is a well characterized phenomenon occurring after allogeneic hematopoietic cell transplantation (HCT). Recently, it has been more often reported after autologous HCT (auto-HCT) and the optimal management is not well established.
Aims: Our objective was to characterize the clinical and biological setting associated with HHV6 reactivation and describe its management.
Methods: We describe here a total of 18 cases of HHV6 reactivations that occurred in patients who received auto-HCT between years 2015 and 2017. There was X (%) males and Y (%) females, the median age at transplantation was 59 years (range: 39-67), diagnosis was lymphoma in majority of cases (N=15, 83%, 6 diffuse large B cell, 3 follicular, 4 mantle cell and 2 T cell), while 3 patients had multiple myeloma (MM). Conditioning regimen was melphalan 200 mg/m² in MM patients and for lymphoma patients it was thiotepa, etoposide, cytarabine melphalan (TEAM), (N=7), BCNU-EAM (BEAM) (N=3), Bendamustin-EAM (N=3) and BCNU-AM (N=2). After transplantation, the median time to neutrophils recovery (neutrophils >0.5 x 10^9/L) was 11 days (range: 9-13).
Results: The predominant symptom that justified the detection of HHV6 was the apparition of fever. (in 14 patients, 78%). The other symptoms were isolated pancytopenia for 3 patients (17%), and one patient had an isolated erythema. The symptoms associated with fever were diarrhea for 3 patients, pneumopathy for 2 patients; erythema for 3 and 1 macrophagic activation syndrome. Sixteen patients received intravenous immunoglobulin after HHV6 reactivation. The other 2 patients had a spontaneous resolution of their symptoms. None of the patients required antiviral therapy for the treatment of the HHV6 reactivation. The HHV6 reactivation did not have an impact on engraftment and hematological recovery.
Summary/Conclusion: We report a retrospective analysis of 18 cases of HHV6 reactivation following autologous stem cell transplant. The majority of the patients was successfully managed with intravenous immunoglobulin, avoiding therefore the possible toxicities of antiviral therapies.

PB2047

CLINICAL AND LABORATORY FEATURES OF INVASIVE ASPERGILLOSIS IN PATIENTS WITH B-CELL LYMPHOMA

J. Chudinovskikh[1], T. Semiglazova[1], O. Shadrivova[2], S. Ignatieva[2], S. Alekseev[1], I. Zuzgin[1], N. Klimko[2,*]

[1]N.N. Petrov National Medical Research Center of Oncology, [2]I.I. Mechnikov North-Western State Medical University, Saint-Petersburg, Russian Federation

Background: Invasive aspergillosis is the predominant invasive fungal infection in patients with haematological malignancies, including patients with B-cell lymphoma.
Aims: To study clinical and laboratory features of invasive aspergillosis (IA) in patients with B-cell lymphoma.
Methods: The study included 57 patients with Hodgkin lymphoma (HL), age from 16 to 65 years (median-33), and 51 patients with non-Hodgkin lymphoma (NHL), age from 19 to 74 years (median-50). For the IA diagnosis criteria EORTS/MSG 2008 were used.
Results: Before the development of IA all patients in both groups received cytostatic chemotherapy, the average number of courses-6. The main risk factors for IA in patients with HL and NHL were: prolonged lymphocytopenia (70% *vs* 48%), neutropenia (64% *vs* 71%), glucocorticosteroids use (61% *vs* 85%), and B-symptoms (63% *vs* 48%). In most cases nosocomial IA was diagnosed in both groups (65% *vs* 83%). The main etiological agents were: A. fumigatus (50% *vs* 39%), A. niger (43% *vs* 33%), and A. flavus (7% *vs* 8%). The lungs were involved in 100% cases, 6% NHL patients had ≥2 organs involvement. Galactomannan test was positive in BAL fluid in 75% patients with HL and in 78% patients with NHL. The presence of septated mycelium was observed at microscopy of BAL in 13% *vs* 22% patients with IA. Aspergillus spp. in BAL culture was obtained in 27% *vs* 47% patients with IA. Clinical manifestation of IA was nonspecific in both groups: fever (83% *vs* 76%), cough (75% *vs* 59%), dyspnea (50% *vs* 40%), bronchial obstruction (4% *vs* 9%), and hemoptysis (2% *vs* 10%). "Probable" IA was diagnosed in 98% of cases, "proven"-in 2% in HL patients, 88% and 12% in NHL patients. Antifungal therapy received 100% patients. The main antifungal drug was voriconazole-88% *vs* 98% cases. Overall 12-weeks survival in patients with Hodgkin lymphoma was 84%, in patients with non-Hodgkin lymphoma-81%.
Summary/Conclusion: The main risk factors for IA in patients with HL and NHL were prolonged lymphocytopenia (70% *vs* 48%), neutropenia (64% *vs* 71%), steroids use (61% *vs* 85%), and B-symptoms (63% *vs* 48%). Etiology agents were A. fumigatus (50% *vs* 39%), A. niger (43% *vs* 33%), and A. flavus (7% *vs* 8%). Clinical symptoms were nonspecific. The overall 12-weeks survival rate in patients with HL was 84%, in patients with NHL-81%.

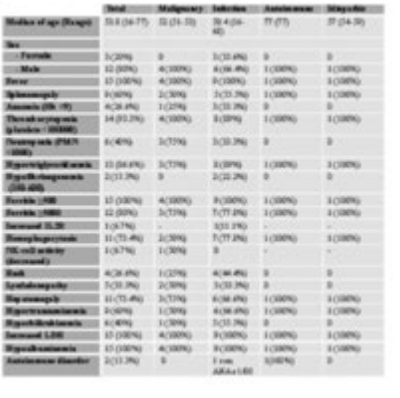
HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS IN THE HEMATOLOGY SERVICE OF A TERTIARY HOSPITAL. RETROSPECTIVE STUDY OF A SERIES OF CASES

R.M. Rodriguez Nuñez*, S. Suárez Ordóñez, A. Nieto Vázquez, C. Insua Vilas, M.D.C. Albo López

Hematology, Hospital Alvaro Cunqueiro, Vigo, Spain

Background: Hemophagocytic lymphohistiocytosis (HLH) is a serious, uncommon and underdiagnosed disease, characterized by an exaggerated inflammatory response due to the activation of macrophages and T lymphocytes; and it requires early diagnosis and treatment. HLH can occur as a family/genetic or sporadic/secondary disorder. It can appear spontaneously or triggered by neoplasms, inflammatory disorders or infections, with Epstein Barr virus (EBV) being the most frequent. Clinical manifestations are not specific, presenting these different signs and symptoms, the most common being high temperature, cytopenia and hepatosplenomegaly.
Aims: The aim of the study was to describe the clinical profile of HLH in a tertiary hospital, from 2011 to the present. We analyzed its etiology, clinical and laboratory characteristics, as well as its evolution and treatment.

Table 1.



Methods: Data were collected from patients diagnosed with HLH at the University Hospital of Vigo from October 2011 to the present. Patients who met the diagnostic criteria proposed by the International Hystiocyte Society in 2004 were included, and those treated for HLH who did not meet the criteria previously mentioned were excluded.
Results: We included 15 cases of HLH, corresponding to 10 patients of which 7 were male and 3 were female, with an overage age of 53.8 years

old (range, 16-77). 9 cases were secondary to infections, 4 to hematological diseases, 1 to autoimmune disorder and 1 was idiopathic. All of the patients were attended to with high temperature and high ferritin. Hemophagocytosis was evident in 11 of the 15 cases (in 2 of them a biopsy of the bone marrow was not performed and in 2 others it was inconclusive). NK-cell activity was studied twice being low in one case. Determination of IL-2R was only carried out in one of the cases being abnormal. In the majority, high temperature disappeared before 10 days, except in four cases in which it remained 12, 14, 16 and 33 days. 5 of them died: 2 cases were secondary to hematological disease, 2 to infection and 1 secondary to autoimmune disorder. Among the received treatments we find: HLH-2004 and HLH-1994 Protocols; conventional chemotherapy in cases related to hemopathy, and treatment of causal infection.
Summary/Conclusion: In our series, as in the literature, the most frequent cause of secondary HLH is EBV infection; being also the most prevalent diagnostic criteria high temperature and high ferritin. In most cases a diagnostic delay is observed, since in the initial moment they did not fulfill enough criteria, due in part to the fact that only in some episodes the determination of NK-cell activity and IL-R2 is done, because of the inaccessibility of the studies. Including HLH in the diagnostic algorithm of persistent febrile syndrome with cytopenias and elevation of acute phase reactants; it would allow an early diagnosis and an early treatment that would improve the prognosis. Likewise, correct etiology and microbiological identification would imply, in our experience, an adaptation of the treatment, avoiding the possible pharmacological toxicity.

PB2049

RISK FACTORS ASSOCIATED TO MORTALITY IN PATIENTS WITH HEMOPATHIES REQUIRING ENTRY IN THE INTENSIVE CARE UNIT

E. Morente Constantin[1,*], A.B. Rivera Gines[1], P. Romero Garcia[2], P.A. Gonzalez Sierra[1], F. Manzano Manzano[3], A. Garcia Ruiz[1], M. Jurado Chacon[1]

[1]Servicio de Hematología y Hemoterapia, Hospital Universitario Virgen de las Nieves, Granada, [2]UCI, Hospital De Santa Barbara, Soria, [3]UCI, Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: Patients who present oncohematological pathology require admission to the ICU at times. Generally this is due to two situations that can sometimes overlap. First, to treat pathologies secondary to their underlying disease, and second, due to complications of the treatment they receive.
Aims: The main objective is to analyze the prognosis of hematological patients who have required admission to the ICU, as well as to study the factors that can modify this prognosis.
Methods: This is a descriptive study of 90 oncohematological patients admitted to the ICU of our center between 2010 and 2015. The following data have been collected: sex, age, date of admission to the ICU, reason for admission to the ICU, baseline homeopathy and if it was active at the time of admission, necessity of mechanical invasive ventilation (MIV) and the number of days, death during admission, haematopoietic progenitor cell transplantation and type, existence of GVHD and neutropenia.
Results: Out of the total of 90 patients, 62 men (68%) and 28 women (32%) were registered. The average age of the patients was 53 years, with an age range of 20 to 83. The overall mortality at admission was 67% (60 patients), and if we divide it by sex we observed that the mortality in men was 69% and in women of 64%. The most frequent hematological pathologies were: 32 patients had non-Hodgkin's lymphoma (35.5%); 19 acute myeloid leukemia, (21.1%); 9 Hodgkin's lymphoma (10%); 6 acute lymphoid leukemia (6.67%); 6 multiple myeloma (6.67%); 4 myelodysplastic syndrome (4.4%); 4 chronic lymphoid leukemia (4.4%); 2 chronic myeloid leukemia (2.2%); 2 polycythemia vera (2.2%). Finally, 1 patient with aplastic anemia, 1 with cardiac amyloidosis and 1 with intracranial plasmacytoma. There are 2 cases with unknown diagnosis. The most frequent causes that triggered the admission are (only or associated): acute respiratory failure, this pathology being the most frequent, since it is presented in 51 patients (56.67%), followed by infections in their different modalities corresponding to 26 patients (28.89%) and finally, heart failure, 9 patients (10%). The fact of requiring MIV was associated with a mortality of 71% (69 patients), a figure that rises to 74% if it is needed for a period of 7 or more days. Of the 26 patients who underwent transplantation of hematopoietic progenitors, 23 died, accounting for 88% of deaths (83% in autologous patients and 90% in allogeneic patients). Of the 61 patients who had their active homeopathy at the time of admission, 37 (60%) died, a figure that reaches 93% (14 out of 15) when they had a GVHD. A total of 34 patients presented neutropenia on admission to the ICU, and 82% died (28).
Summary/Conclusion: Patients with oncohematological diseases have a higher risk of presenting complications that require admission to the ICU. They also represent a type of patient with a high mortality after admission (overall mortality of 67%). According to our study, the situations that are linked to a higher mortality are: active GVHD (93% mortality), being a transplant recipient (88%), neutropenia (82%) and requiring MIV (71%).

PB2050

THROMBIN GENERATION MAY BE A PROGNOSTIC MARKER IN CHILDREN WITH FEBRILE NEUTROPENIA

A. Koca Yozgat[1], I. Eker[2,*], O. Gursel[3], M.F. Kılınckaya[4], D. Ozyoruk[1], A. Kara[5], N. Yaralı[5], N.Y. Ozbek[5]

[1]Pediatric Hematology and Oncolgy, Pediatrics Hematology Oncology Training and Research Hospital of Ankara Health Sciences University, Ankara, [2]Pediatric Hematology, Afyon Kocatepe University, Afyonkarahisar, [3]Pediatric Hematology, Gulhane Training and Research Hospital of Ankara Health Sciences University, [4]Biochemistry, Numune Training and Research Hospital, [5]Pediatric Hematology and Oncology, Pediatrics Hematology Oncology Training and Research Hospital of Ankara Health Sciences University, Ankara, Turkey

Background: Febrile neutropenia is a common occurrence in pediatric hematology patients due to myelosuppressive chemotherapy. Sepsis, which is an amplified, body-wide inflammatory response to an infection, is observed in 50% of patients with febril neutropenia. Effective management of sepsis during neutropenia stage could reduce the mortalities of cancer treatments. In addition to its direct role in promoting and regulating clot formation, it is documented in recent years that thrombin is a key component of inflammatory response also. It both regulates and enhances inflammatory responses against infections and tissue damage.
Aims: In our study, we aimed to observe the changes in thrombin formation in febrile neutropenia patients. Also we evaluate whether the amount of thrombin formation could be implified as a prognostic marker in febrile neutropenia.
Methods: Recruitment of patients took place at the Pediatric Hematology and Oncology Department of Pediatrics Hematology Oncology Training and Research Hospital of Ankara Health Sciences University between January to August 2016. Thrombin levels were measured by Thrombin Generation Test (TGT) by flourogenic method. Endogenous thrombin potentials (ETP; Total Thrombin Level in Samples) of 35 patients were evaluated. Results of patients were compared to results of 50 healthy children. Platelet Poor Plasma Samples of febrile neutropenia group were collected at initial admission, at 48.th hour and after recovery from neutropenia.
Results: Patient's mean day of recovery from neutropenia was 19.8±11.7 (min-max: 7-49). Mean ETP value at the 48th hour (1998±1037 nanomol x minute) was statistically higher than the mean ETP value of the initial admission (1471,8±582 nanomol x minute) (p:0.007), mean ETP value of control group (1260±267 nanomol x minute) (p:0.001) and mean ETP value of the time when neutropenia resolved (1492±530 nanomol x minute) (p: 0.008). Mean peak value of thrombin at the 48th hour (386±239 nmol/L) was statistically higher than the mean peak value of the initial admission (271±112 nmol/L) and the mean peak value of the time when neutropenia diminished (297±123 nmol/L) (p:0.02).
Summary/Conclusion: Thrombin is a multifunctional protein involves in coagulation, anticoagulation, platelet activation, endothelial activation, production of growth factors and proliferation of both smooth muscle cells and fibroblasts. Sepsis; is the main cause of mortality in the neutropenic phase following the treatment of malignancies. Our results support that thrombin formation may be used as a prognostic marker in pediatric patients with febrile neutropenia associated with chemotherapy, there is a need for further studies in larger subject groups.

PB2051

FACTORS CONTRIBUTING TO SEVERE PNEUMONIA IN PATIENTS AGAINST HEMOTOLOGICAL MALIGNACIES

Borisova*

Department of Medical and Social Expertise and Rehabilitation, State Establishment "Dnepropetrovsk Medical Academy of Health Ministry of Ukraine", Dnipro, Ukraine

Background: According to the World Health Organization, for the period from 2000 to 2012 among the 10 leading causes of death in the world, lower respiratory tract infections took 4th place. In patients with hemoblastomas, the problem of diagnosis and treatment of pneumonia is due to the high incidence, lack of clinical manifestations, severe course, frequent complications and rapid development of fatal consequences.

Aims: To determine the factors which cause the severity of pneumonia based on the study of a complex of clinical and laboratory, anamnestic and immunological parameters of patients with severe immunity disorders on a background of oncohematological diseases.
Methods: To solve this problem, a computer database was created from the results studies of retrospectively analyzed archival data of 605 cases of hospitalizations and the results of a prospective study of 276 cases of hospitalization of patients with oncohematological diseases in "City Multidisciplinary Clinical Hospital No. 4", Dnipro, Ukraine, 2010-2015.
Results: The results of the study proved that the severity of pneumonia and the unfavorable prognosis of the disease were most influenced by factors that can be conventionally grouped into groups: indicators characterizing oncohematological disease (age of the patient (p=-0.25, p<0.001), the form of oncohematological disease (p=0,29, p<0,001); the number of courses of HT (from 8) (p=0,33; p<0,001); anemia (p=0,61; p<0,001); presence of neutropenia (p=0, 46, p & lt; 0.001); indicators characterizing the inflammatory process in the lungs (Gp - pathogens (p=0.48, p<0.001); presence of complications: hemoptysis (p=0.36, p<0.001), pleurisy (p=0.58, p<0,001), respiratory failure (p=0,32, p<0,001); presence of cough (p=0,30; p<0,001); wet wheezes (p=0,48; p<0,001); ESR (p=0.38; p<0.001) and indicators of immune reactivity, characterizing the degree of immunodeficiency.
Summary/Conclusion: When the overall variance was determined, which determines the factors that cause the severity of pneumonia and the occurrence of an unfavorable prognosis in patients with oncohematological diseases, the contribution of the degree of immunodeficiency was about 52%.

PB2052

THE DYNAMICS OF PROTEIN C IN AN INFECTIVE CHRONIC SYSTEMIC INFLAMMATORY CONDITION: HUMAN IMMUNO DEFICIENCY VIRUS INFECTION

E. Chukwuka[1,2,*], O. Awodu[1]

[1]Haematology and Blood Transfusion, University of Benin Teaching Hospital, Benin, Nigeria, [2]Laboratory Department, Maternity and Children Hospital, Al Mubaraz, Saudi Arabia

Background: Human Immunodeficiency Viral (HIV) infection is a chronic systemic inflammatory and thrombogenic condition. Protein C has well defined anticoagulant functions, however, its anti-inflammatory functions which act distinctively from the 'anticoagulants', with regards to structure, receptor, signaling pathway and effect, is an exploit of current active research. Understanding the dynamics of this protein in a condition like HIV infection may give some insight to the functionality of this unique molecule particularly in the Nigerian setting.
Aims: To determine the levels of protein C, some inflammatory markers; Erythrocyte Sedimentation Rate (ESR) and C-reactive Protein (CRP) and d-dimer (a marker of ongoing coagulation) in HIV infected patients and evaluate the relationship between protein C and these parameters.
Methods: This is a cross-sectional study that assessed the activity of Protein C using chromogenic methods (Technochrom), ESR using Westergreen method, CRP and D-dimer using ELISA test kits (Agappe and Immunoclon respectively) in a total of 210 participants comprising of three groups; HIV seronegative participants (n=70), HIV seropositive therapy naive participants (n=70) and HIV seropositive participants on HAART (n=70). Informed consent from each participant and an approval from the medical ethical committee of the institution where study was conducted were obtained.
Results: The mean protein C level in the seronegative, HAART naïve and HAART experienced participants were 0.618±0.446 IU/ml, 0.548±0.473 IU/ml and 0.340±0.226 IU/ml respectively. There was a significant difference between the mean of the HAART naïve and HAART experienced participants (p<0.001). The mean ESR and CRP in the seronegative, HAART naïve and HAART experienced participants were 21.1±14.3mm/hr and 18.77±17.51mg/dl; 71.2±41.1mm/hr and 39.92±27.28mg/dl; and 40.8±35.3mm/hr and 27.99±21.54mg/dl respectively. There was a significant difference across the three groups of participants (p<0.001). The mean d-dimer levels for therapy naïve was 168.0±41.0 mg/L and 168.0±17.0 mg/L for the HAART experienced, the mean difference was statistically significant when compared with the seronegative participants (92.0±11.0 mg/L) p<0.001. The correlation between protein C and other parameters assessed only showed a significant correlation with ESR (r=0.36, p<0.001).
Summary/Conclusion: ESR and CRP levels were significantly higher in HIV infected participants, though participant on HAART were associated with a much lower level of inflammatory markers. D-dimer levels were significantly higher with HIV infection and the elevations persisted despite HAART. Protein C levels were significantly lower with HAART when compared with the other groups of participants. Hemostasis is grossly altered in HIV infection despite an associated reduced inflammatory state with HAART.

PB2053

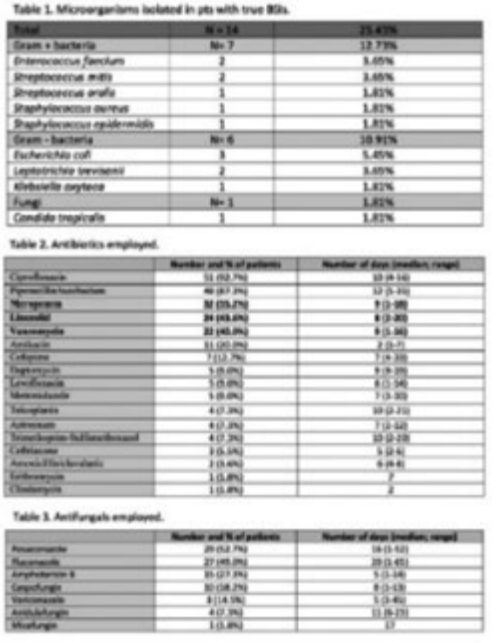
ANALYSIS OF INFECTIONS AND USE OF ANTIMICROBIALS IN PATIENTS UNDER-GOING INTENSIVE INDUCTION CHEMOTHERAPY FOR NEWLY DIAGNOSED ACUTE MYELOGENOUS LEUKEMIA

A. Aranbarri Larrañaga*, C. Lombardi Iglesias, L. Ondarra Segurola, I. Otero Longo, A.N. Bizjak Gómez, M. Araiz Ramirez, J.C. Vallejo LLamas

Hematology, University Hospital Donostia, San Sebastian, Spain

Background: It is known that patients undergoing intensive induction chemotherapy (IIC) for acute myeloid leukemia (AML) have a high risk for developing infectious complications.
Aims: To describe microbiologically documented infectious episodes, the use of antimicrobials and the outcome of all consecutive patients undergoing IIC for newly diagnosed AML during the last 4 years.
Methods: A total of 111 adult patients were diagnosed with AML at the Donostia University Hospital from 2014 to 2017. Patients with AML-M3 (8 pts) and those who did not receive IIC (48 pts) were excluded for this analysis. In total, 55 pts were treated with IIC: 50 with Ida + Ara-C (3 + 7) and 5 with Flag-Ida. The median age was 61 years (23-78). 30 were men and 25 women. Most of the pts (88%) stayed in HEPA-filtered rooms.
Results: Median hospital admission was 30 days (22-77). Five pts (9.1%) died during admission. Thirty one pts (56.4%) achieved complete remission after the IIC. A total of 336 blood cultures (BC) were performed (average: 6.11 BC/pt, range: 1-17). 21 BC (6.25%) were positive (false positives were excluded). Fourteen pts (25.45%) had at least 1 true bloodstream infection (BSI), whose characteristics are shown in Table 1. Other cultures performed were: urine (136), stool (98) and others (38). The antimicrobials used are shown in Tables 2 and 3. Only one of the 5 pts who died was due to infectious mortality (1.81%) (sepsis due to *Candida tropicalis*). No other IFI cases were documented.

Table 1.



Summary/Conclusion: 1) fungal BSIs, in general, and IFI incidence, in particular, were very low in this group of high risk pts (1.81%). This fact could be attributed to the combination of several factors: a) the majority of the pts stayed in HEPA-filtered rooms; b) the antifungal prophylaxis used; c) the use of empirical antifungal therapy for prolonged neutropenic fever. 2) Bacterial BSIs were relatively frequent (23.64%) among patients undergoing IIC for newly diagnosed AML. Gram + bacteria (12.73%) were slightly predominant over Gram - bacteria (10.91%). There was no mortality due to a bacterial infection. Our analysis shows, however, a high consumption of carbapenems (55.2% of pts), vancomycin (43.6% of pts) and linezolid

(22% of pts). Due to the growing concern and awareness of the problems of antibiotic resistance around the world, we recently implemented a new protocol for the management of fever, more conservative and restrictive, with the hope of reducing the use of unnecessary antibiotics, maintaining the low rate of infectious mortality.

PB2054

MOLECULAR DETECTION OF CYTOMEGALOVIRUS DNA IN ADULT EGYPTIAN PATIENTS WITH ACUTE LEUKEMIA RECEIVING CHEMOTHERAPY

M. Halaby[1,*], A. Nazir[1], N. Zaki[1], G. Helaly[2], F. Elsayed[1], S. Shawky[2]

[1]Internal Medicine Hematology unit, alexandria university faculty of medicine, [2]Microbiology, medical research institute, alexanderia, Egypt

Background: There are abundant data on the pattern and time course of CMV reactivation or primary infection in allogeneic stem cell transplant (allo-SCT) recipients, and well-defined strategies have been developed for prophylaxis, screening and preemptive treatment.(1) However, there is a remarkable paucity of data regarding CMV reactivation in adult patients with acute leukemia (AL) receiving chemotherapy. Re-activation can lead to prolonged cytopenias, fever and other manifestations, which are often misdiagnosed and treated empirically with antimicrobials.(2)
Aims: To investigate the prevalence of CMV DNA and its possible re-activation in adult Egyptian patients with AL receiving chemotherapy.
Methods: The study was on conducted on 63 Egyptian adult patients with newly diagnosed AL,admitted to the Hematology Unit,Internal Medicine Department, Alexandria Main University Hospital. The patients included 36 AML and 27 ALL cases. CBC, bone marrow aspiration and immunophenotyping were done at presentation. Patients were treated according to 3+7 standard protocol for AML and Larson protocol for ALL and were followed up clinically and by microbiological investigations on days 0, 14, 28 and 100 from the start of induction chemotherapy. CMV DNA was detected by real-time PCR on day 0 and day 100.
Results: AML patients included 16 males and 20 females with an age ranging from 18 to 57 years with a mean of 38.36±11.98 years. ALL patients were 17 males and 10 females and included 21 B-ALL and 6 T-ALL cases. Their ages ranged from 18 to 59 years with a mean of 26.19±10.24 years for B-ALL and from 19.0 to 43.0 years with a mean of 26.83±9.20 years for T-ALL. 100% of enrolled patients were neutropenic and febrile on day 14. Positive blood cultures for bacteria were obtained in 72.2% of AMLs and 76.9% of ALLs. Invasive sino-pulmonary fungal infection was diagnosed in 25% of AMLs, 30% of B-ALLs and 66.7% of T-ALL patients. By day 28, complete remission (CR) was achieved in 70.8% of AML and 80% of ALL patients, partial remission in 8.3% of AMLs and 5% of ALLs, while 20.8% of AML and 22.2% of ALL patients were refractory to induction chemotherapy. Mortality at day 28 was 33.3% and 22.2% in AML and ALL patients; respectively. None of the studied patients exhibited symptoms or signs related to CMV during the whole follow-up period. No CMV DNA was detected by real-time PCR neither on day 0 nor on day 100 among all AL patients enrolled in the study. Six out of patients in CR underwent allo-SCT from an HLA-related sibling and all of them were seropositive for CMV IgG and negative for CMV IgM throughoutand for 6 months following the transplant procedure.
Summary/Conclusion: Although CMV infection or re-activation is a serious problem in immunocompromised patients, yet it seems from ourresults that adult patients with de-novo AL do not have the same risk as neither they manifest nor CMV DNA was detected by PCR on days 0 and 100 from the initiation of standard induction chemotherapy. However,we recommend further studies with larger samples, different chemotherapy protocols and for longer follow-up period to confirm the status of CMV infection/re-activation in adult AL patients especially among those who are candidates for allo-SCT.

PB2055

ACUTE HEPATITIS E OCCURRING IN ONCOHEMATOLOGIC PATIENTS: A SINGLE CENTRE EXPERIENCE

N.S. Fracchiolla[1,*], V. Mattiello[1], L. Pettine[1], A. Freyrie[1], M.C. Goldaniga[1], L. Baldini[1], F.G. Rossi[1], A. I. Gregorini[1], V. Ferla[1], M. Sciumè[1], G. Lunghi[2], S. Piconi[3], A. Cortelezzi

[1]Oncohematology Division, IRCCS Ca' Granda - Maggiore Policlinico Hospital Foundation and University of Milan, [2]U.O.S Virology, IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico di Milano, [3]Division of Infectious Diseases Unit, University of Milano, Ospedale L. Sacco, Milan, Italy

Background: Hepatitis E virus (HEV) is a zoonosis mainly transmitted via oral-fecal route. Recent reports confirmed that HEV infection can be also transmitted through the transfusion of blood products in immunocompromised patients. HEV infection varies from a simple acute hepatitis with spontaneous recovery to acute liver failure and to chronic infection in immunosuppressed patients.
Aims: To describe two cases of acute HEV infection occurring in two patients with hematologic malignancies.
Methods: Adult patients with Non-Hodgkin lymphoma who developed HEV infection were selected from the institutional database.
Results: A 67-year-old man (pt 1) diagnosed with advanced stage peripheral T-cell lymphoma underwent multiple cycles of chemotherapy (6 CHOEP and 4 GDP) and autologous stem cell transplantation (ASCT) in partial remission. At transplantation the patient was negative for anti-HEV immunoglobulins. Three months after ASCT abrupt onset of diarrhea, weight loss, jaundice and rising in liver tests, prompted evaluation and hospital admission. Laboratory studies revealed AST 832 UI/L, ALT 1128 UI/L, and raised cholestatic liver enzymes (gGT 456 UI/L, total bilirubin 9.4mg/dl, direct bilirubin 8,4mg/dl). A 65-year-old man (pt 2) diagnosed with IV-B stage DLBCL started HyperCVAD. Viral serology before chemotherapy was negative. The first cycle of therapy was complicated by the increase of transaminases and cholestasis levels: AST 347 UI/L, ALT 365 UI/L, gGT 407 UI/L, total bilirubin 4.9mg/dl, direct bilirubin 3.5mg/dl. Both pts underwent RBCs and platelets transfusions. Hepatitis A, B, C, EBV and CMV infections were ruled out, autoimmunity tests were negative. Abdomen ultrasound did not reveal biliary ducts dilation, nor focal hepatic lesions. In pt 1, anti-HEV IgM and HEV RNA in the serum were positive, while pt 2 was positive only for HEV-RNA ($1.3x10^6$ genomes/ml) but tested negative for IgM and IgG. Diagnosis of acute HEV infection was confirmed. No immunosuppressive therapy was ongoing. Possible routes of infection were investigated: no contact with animals, no travels to endemic countries and no additional cases of HEV infections were reported at our unit during their hospitalization. Close monitoring of RNA-titer of the first patient showed progressive decrease of serum copies (36720 copies/ml à 1538 copies/ml); HEV-RNA was no longer quantifiable during serological controls after one month. Symptoms and liver function tests improved during admission with the sole supportive care. Excluding virus persistence, no antiviral treatment with ribavirin was started. To pt 2 was given ribavirine therapy, 600 mg for six months, for prolonged detection of serum HEV-RNA. Progressive reduction of HEV-RNA titer together with decrease of hepatic enzymes was observed with close monitoring, and clearance after four months from diagnosis was detected.
Summary/Conclusion: Acute hepatitis E case reports have increased in recent years in developed countries. Systematic HEV RNA screening of all blood donation is under consideration and already implemented in some Western countries as the risk and importance of transfusion-transmitted HEV infections by contaminated blood products is currently a controversial topic in transfusion medicine. A model estimates that receiving blood components from 13 donors carries a similar risk to one year of dietary exposure. The present report suggests that patients with hepatitis who have received blood products should be screened for HEV, especially if immunosuppressed.

PB2056

INFECTIOUS COMPLICATIONS IN FIRST THREE CYCLES OF AZACITIDINE DID NOT NEGATIVELY IMPACT OVERALL SURVIVAL OF MYELODYSPLASTIC SYNDROME PATIENTS

Z.X. Ng[1,*], B.M.H. Keng[1], Z.Y. Myint[2], G.C. Wong[3]

[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [2]Singapore General Hospital, Singapore, Singapore, [3]Department of Haematology, Singapore General Hospital, Singapore, Singapore

Background: It is well known that infectious complications (ICs) may occur frequently in patients with myelodysplastic syndrome (MDS) on azacitidine treatment. These ICs may reduce the success rate of therapy. We retrospectively examined the clinical course of 49 patients treated with azacitidine at a large tertiary hospital in Singapore between 2010 and 2016, and evaluated if ICs affected their survival.
Aims: This paper aims to evaluate the incidence and mortality of infectious events in patients with MDS who receive azacitidine treatment, predisposing risk factors for infections, the value of antimicrobial and antifungal prophylaxis, and clinical parameters affecting survival.
Methods: Clinical data of MDS patients were obtained from our Institution Review Board-approved database. These included severity of MDS using the IPSS-R score, number of cycles and responses to azacitidine, number of days of hospitalisation, type of ICs, presence of comorbidities, absolute neutrophil count (ANC) at diagnosis, and overall survival (OS).

Results: A total of 307 cycles of azacitidine were administered to 49 patients (mean age 64.5±12.3 years). All patients received antibacterial prophylaxis, and all but 5 received antifungal prophylaxis. The median number of cycles was 5 (range 1-42). Thirty-two patients had at least one IC. In patients who received at least 6 cycles of azacitidine, IC rates were not higher in the first three cycles of treatment compared to the next three cycles. ICs in the first three cycles of treatment were not associated with lower OS as compared to no ICs within the first three cycles (p=0.069). IC rates were correlated with number of days hospitalised (p<0.001), but not correlated with age, response to treatment, IPSS-R score, or ANC at diagnosis. Median OS from date of diagnosis was 12 months (range 1-113 months). OS was correlated with age (p=0.007), IPSS-R score (p=0.01), number of cycles (p=0.027), and response to treatment (p=0.024), but not ANC at diagnosis. Infections were predominantly bacterial, with none of our patients experiencing any fungal infection.
Summary/Conclusion: The presence of infectious complications in the first three cycles of azacitidine therapy did not negatively impact overall survival. Age, response to treatment, IPSS-R score, and ANC at diagnosis did not predict for infectious complications. Antibacterial and antifungal prophylaxis may have beneficial effects.

PB2057

INFECTIONS IN PATIENTS WITH LYMPHOMA: AN ANALYSIS OF INCIDENCE, RELATIONSHIP AND RISK FACTORS

A. Yildiz[1,*], M. Albayrak[1], Ç. Pala Öztürk[1], O. Şahin[1], H.B. Afacan Öztürk[1], G. Güneş[1], S. Maral[1], H. Okutan[2]

[1]Hematology, University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, [2]Hematology, Lösante's Children and Adult Hospital, Ankara, Turkey

Background: Bacterial infections and febrile neutropenia are major causes of morbidity and mortality in patients with hematological malignancy.
Aims: The aim of this study was to investigate the incidence and risk factors of infections in lymphoma patients.
Methods: This retrospective study was conducted on 200 lymphoma patients diagnosed and treated between January 2009 and December 2017 in Diskapi Yildirim Beyazit Training and Research Hospital, a tertiary referral hospital in Ankara, Turkey. A total of 65 patients developed at least one infection episode (IE) while 37 patients developed febrile neutropenia (FN).
Results: The mean follow-up period was 20.09±19.81 months. The incidence of IE was 32.5% (65/200) and FN was 18.5% (37/200). Analysis of the data revealed that the patients with IE had significantly higher diagnosis of central nervous system lymphoma (CNSL), lower baseline hemoglobin, lower baseline hematocrit, higher baseline lactate dehydrogenase levels, higher usage of central cathater, and a higher number of chemotherapy lines compared to patients with no IE. In logistic regression analysis, disease subtype of CNSL, usage of central catheter and LDH were found to increase the risk of infection. The OR for CNSL was 37.866 (p=0.003), 2.679 for central catheter (p=0.008) and 1.001 for LDH (p=0.011).
Summary/Conclusion: The risk of infection in patients with lymphoma was associated with central catheter usage, higher LDH levels and a diagnosis of CNSL. Baseline hematological parameters were not determined to have any impact on the occurrence of infection. Clinicians must be aware of these data soon after diagnosis as they will be required for the management of lymphoma patients through the whole period.

PB2058

INVASIVE SCEDOSPORIOSIS AND LOMENTOSPORIOSIS IN PATIENTS WITH HEMATOLOGICAL DISEASES IDENTIFIED IN THE LITERATURE AND THE FUNGISCOPE™ REGISTRY

D. Seidel[1,*], A. Meißner[1], M. Lackner[2], M. Stecher[1], S. Mellinghoff[1], L.A. Durán Graeff[1], J. Salmanton Garcia[1], A. Hamprecht[1], M.J. Vehreschild[1], P. Köhler[1], H. Wisplinghoff[3], J.J. Vehreschild[1], O.A. Cornely[1]

[1]University Hospital Cologne, Cologne, Germany, [2]Medical University of Innsbruck, Innsbruck, Austria, [3]Laboratory Wisplinghoff, Cologne, Germany

Background: Hematological malignancies and their treatment are main risk factors for invasive fungal infections (IFD). Less frequent IFD such as scedosporiosis and lomentosporiosis (IS/IL) are emerging complications in such patients, with mortality rates up to 90%. Efficient diagnostic and treatment approaches for IS/IL are not known or validated yet. Furthermore, intrinsic resistance to almost all available antifungals hamper appropriate treatment decisions.
Aims: Clinical data were collected, to describe clinical presentation and management of IS/IL in hematological patients and to identify effective treatment strategies.
Methods: Data of probable and proven IS/IL cases collected from the literature and FungiScope™, an international web-based registry, were analysed. Data collected include demographics, underlying conditions, sites of infection, antifungal treatment, susceptibility to antifungals and outcome.
Results: Clinical data of 29 patients with infections caused by *Scedosporium* spp. and 28 by *Lomentospora prolificans*) with a hematologic disease were collected. Most patients had acute leukaemia (52.6%), lymphoma (15.8%) or chronic leukaemia (8.8%); 29.8% received allogeneic HSCT. Blood stream infection was confirmed in 21 (75%) IL patients and 1 (3.4%) IS patient. Other most frequently affected organs were lung, eye and CNS (49.1%, 24.6%, 19.3%). All patients received antifungal drugs for treatment (median 22 days, IQR 5-92 days) and 28.1% patients were surgically treated in addition. *L. prolificans* isolates had MICs of 1 mg/L and higher for amphotericin B, voriconazole, posaconazole, and caspofungin. *Scedosporium* spp. isolates had voriconazole MICs of 1 mg/L and lower. Most patients were treated with voriconazole (68.4%) and/or amphotericin B (56.1%). Terbinafine in combination with voriconazole was frequently used for treatment of IL (35.7%). Day-42 and overall mortality was higher in IL (71.4% and 85.7%) than IS patients (27.6% and 55.2%).
Summary/Conclusion: IS/IL are rare, life threatening diseases in hematological patients. Despite aggressive antifungal treatment strategies, outcome remains poor. More effective treatment strategies are urgently needed to improve patient outcome.

PB2059

CLASSICAL OR ALTERNATIVE COMPLEMENT PATHWAY INHIBITION ALONE DOES NOT PREVENT WHOLE BLOOD KILLING OF ANTIBODY-COATED N. MENINGITIDIS OR S. PNEUMONIAE

L.A. Lewis[1], S. Panicker[2], R.B. De Oliveira[1], G.C. Parry[2,*], S. Ram[1]

[1]University of Massachusetts, Worcester, MA, [2]Bioverativ Therapeutics Inc., Waltham, MA, United States

Background: The complement cascade, responsible for the detection and clearance of pathogens, is activated by the classical (CP), lectin (LP) or alternative (AP) pathways, each of which can be independently activated by pathway-specific pattern recognition receptors. However, aberrant complement activation is observed in numerous diseases. While therapeutic complement inhibition at the level of C5 has proven to be a successful approach for treating various diseases, it is associated with an increased risk of infection, in particular, invasive meningococcal disease, even when vaccinating prophylactically. Targeting pathway-specific components provides the theoretical advantage of selectively inhibiting the pathway that triggers disease pathogenesis, while leaving the other pathways intact for immune surveillance.
Aims: Here we aimed to address the potential increased infection risk associated with complement pathway specific inhibition using a C1s inhibitor (TNT005; CP inhibitor), and a factor Bb inhibitor (anti-fBb; AP inhibitor). We performed *in vitro* bactericidal (complement-mediated) and whole blood killing assays (complement- and immune cell-mediated) to assess the relative contribution of the CP and AP in killing *N. meningitidis* and *S. pneumoniae.*
Methods: Experiments were performed using *S. pneumoniae* strain TIGR4 and group C *N. meningitidis* strain 4243. Flow cytometry was used to measure deposition of C3 and C4; pathway specific inhibitors were used to determine the relative contribution of the different pathways in depositing opsonizing complement fragments on bacteria. Bactericidal experiments in normal human plasma and whole blood killing assays containing both intact complement and phagocytes, were performed in the presence of CP and AP inhibitors (either alone or in combination). Experiments were performed in the presence or absence of capsular antibody to mimic vaccinated and non-vaccinated states, respectively.
Results: Inhibiting the CP alone using saturating concentrations of TNT005 prevented C4 deposition and killing of *N. meningitidis* in both normal human plasma and whole blood. However, in whole blood killing assays that contained specific anti-meningococcal antibodies, simultaneous inhibition of both the CP and AP was required to prevent killing of antibody-coated *N. meningitidis.* For antibody-coated *S. pneumoniae*, anti-fBb alone completely blocked C3 deposition, whereas TNT005 only partially inhibited (~40% decrease in fluorescence) C3 deposition. As expected, killing of *S. pneumoniae* was observed only in whole blood in the presence of phagocytes; blocking either the CP or AP alone did not impair killing of pneumococci in the presence of specific antibody (>90% killing at 3 h), but blocking both pathways resulted in >50% bacterial survival at 3 h.
Summary/Conclusion: The data presented here suggest that antibody-coated *N. meningitidis* can activate both the CP and AP of complement, and that

inhibition of either pathway alone would not significantly affect *N. meningitidis* killing in the presence of anti-*N. meningitidis* antibodies as membrane attack complex mediated killing could still occur via the unblocked pathway. Antibody-mediated killing of *S. pneumoniae*, which requires phagocytes, also proceeded in an unimpeded manner when the CP or AP were blocked individually. These data suggest that vaccination against *N. meningitidis* and *S. pneumoniae* is critical and likely to be effective when administering a therapeutic CP or AP inhibitor.

PB2060

PRESEPSIN (SOLUBLE CD14 SUBTYPE) AS A DIAGNOSTIC MARKER OF BACTERIAL INFECTIONS IN FEBRILE NEUTROPENIC PEDIATRIC PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

A. Abd El-Kreem[1,*], M. Hosam EL-Dein[1], A. Baraka[1], M. Zakaria[2]

[1]Clinical Pathology, [2]Pediatrics, Zagazig University Hospitals, Zagazig, Egypt

Background: Febrile neutropenia (FN) is one of the most common complications in patients with hematological malignancies which is caused by chemotherapy and the underlying disease. C-reactive protein (CRP) and procalcitonin (PCT) have been used as diagnostic markers of infections but they have some limitations. Recently, soluble CD14 subtype (sCD14-ST), also known as presepsin was reported as a novel and promising biomarker for the diagnosis of sepsis. However, its usefulness in identifying infections in patients with hematological malignancies during episodes of fever and neutropenia remains unclear.
Aims: The aim of this study was to evaluate the usefulness of presepsin compared to CRP and PCT as an early diagnostic marker of infections in FN patients with hematological malignancies.
Methods: In addition to blood cultures, we have measured presepsin, CRP and PCT, in 60 individuals. 30 of them were pediatric patients with hematological malignancies during episodes of fever and neutropenia (serving as patients group) and the other 30 were apparently healthy age and sex matched individuals (serving as control group), all of them participated in the study after consent of their relatives. patients were subclassified into 3 subgroups (patients with fever of unknown origin (FUO), patients with bacteremia, patients with clinically proved infections in the form of mucositis, pneumonia, urinary tract infection, neutrpenic enterocolitis). The sensitivity and specificity of the three biomarkers were compared in the 3 subgroups.
Results: Prespsin levels were significantly higher in bacteremia patients than those with FUO and clinically proved infections. In contrast CRP levels didn't show significant increase in bacteremia patients than those with clinically proved infections, also PCT levels were not significantly higher in clinically proved infections patients than FUO patients. Our study showed that there were slight elevation in presepsin levels in gram negative cultures than in gram positive cultures but this rise was not statistically significant. This study also showed that there was statistically significant negative correlation between presepsin and absolute neutrophil count (ANC) which also correlates with the severity of infections. The reliability of presepsin was higher than that of PCT and CRP in prediction of bacteremia in FN patients where the sensitivity of presepsin ,PCT and CRP was (100%, 100%, 77.8% respectively),and the specificity was (85.7%, 81%, 66.7% respectively). Presepsin was also superior to CRP and PCT in identification of bacterial infections either in the form of bacteremia or clinically proved infections with sensitivity (100%, 100%, 68.8% respectively) and specificity (100%, 64.3%, 85.7% respectively).
Summary/Conclusion: Presepsin can be used as a discriminator of infectious and non infectious origin of fever in FN patients with hematological malignancies even with very low total leucocyte count and ANC due to chemotherapy. The combination of presepsin and CRP may improve the sensitivity and specificity for prediction of bacterial infections in those patients.

PB2061

SALVAGING DISSEMINATED CUTANEOUS MUCORMYCOSIS WITH TRIPLE ANTI-FUNGAL THERAPY PLUS GRANULOCYTE INFUSION

K. Mullanfiroze[1,*], S. Tulpule[2], T. Singhal[1], S. Gupta[2], S. Sen[1]

[1]Dept of Paediatric Oncology & BMT, [2]Dept of Oncology & BMT, Kokilaben Dhirubhai Ambani Hospital, Mumbai, India

Background: Invasive fungal infections (IFI) needs a prompt identification of the fungus and aggressive anti-fungal treatment along with reversal of neutropenia and immunosuppression.
Aims: We describe a case of Mucormycosis where aggresive antifungal therapy & granulocyte infusions led to a successful outcome.
Methods: 13 year old child with Acute Lymphoblastic Leukemia (NCI-HR with CNS-2 status at presentation) was on UK-ALL 2003 high risk protocol. He presented in week 4 of induction with multiple tender skin lesions over the body. Lesions were ovoid with black discoloration and ulceration of the central region with a surrounding rim of erythema. On enquiry, parents reported the presence of a damp wall in their residence which was probably the source of his infection. He was initially afebrile with CBC - Hb 7.5 g%, TLC 310/mm^3 (0% neutrophils), platelet count 62000/mm^3. He was empirically started on parenteral antibiotics along with anti-fungal therap with liposomal amphotericin-B and Voriconazole. Bedside skin biopsy from the lesion was performed and sent for bacterial, fungal culture and histopathology. KOH mount on the biopsy was suggestive of budding yeast with hyphae. In view of progressive increase of the size of the lesions, deterioration of clinical condition with high grade fevers, inj.Caspofungin was also added. Dexamethasone was rapidly tapered and stopped. He was also given growth factors(inj. G-CSF at 10 mcg/kg/day subcutaneously q24 hourly) and granulocyte infusions(1x10^{10}/recipient body weight kg) until absolute neutrophil count (ANC) increased to more than 1000/mm^3 for 2 consecutive days. CT chest was suggestive of 8 mm nodule in the right side of the lung. With supportive care and above medications, his clinical condition and CBC started improving by day 6 of hospital stay. On day 7 of hospitalisation, he started having restlessness, anxiety, disorientation to time and person along with hallucinations and urinary and bowel incontinence followed by intermittent episodes of aphasia and aggressive behaviour. MRI brain was normal. In view of a normal MRI and worsening of CNS symptoms, voriconazole induced adverse reaction was suspected and it was withdrawn and Posaconazole was started. His GCS gradually started improving and he also regained bowel and bladder continence. The skin biopsy was reported as Mucor. His hallucinations and restlessness reappeared and hence posaconazole was stopped and amphotericin-B and caspofungin were continued. However, few days later he developed generalised erythematous, macular- papular, pruritic skin rash on his trunk region. Amphoericin-B induced hypersensitivity was suspected and hence it was also discontinued. He was then re-challenged with posaconazole and this time,he tolerated it well.
Results: Currently,the skin lesions have healed completely and in view of the final characterisation of the isolated fungus being reported as Mucormycosis, caspofungin has been withdrawn and he is on single agent posaconazole. Currently, the patient is well and skin lesions have healed completely.
Summary/Conclusion: There is extreme morbidity caused by IFI in neutropenic children. Combination anti-fungals, reducing immunosuppression and rapidly increasing the neutrophil count is essential, for the treatment of severe IFI. Avoidance of exposure to damp walls, seepage and construction areas must be emphasised to the care givers of neutropenic and immunosuppressed children.

PB2062

A CASE OF CYTOMEGALOVIRUS-INDUCED PANCYTOPENIA WITH CMV COLITIS

O. Apanasenko*

Kiev center of bone marrow transplantation, KIEV, Ukraine

Background: CMV infection is one of the important causes of morbidity and mortality after HSCT. It may manifest by involving multiple organs such as intestines, lungs, bone marrow, central nervous system involvement and others.
Aims: We describe a case of cytomegalovirus-induced pancytopenia with CMV colitis in patient after allogeneic stem cells transplantation from an unrelated donor for a secondary ALL.
Methods: A 19-year-old man underwent an allogeneic HSCT following conditioning with fludarabine, ATG, thiosulphane. He had received cyclosporine and corticosteroids for acute, then chronic GVHD with skin, liver and gastrointestinal involvement. On D+150 serum CMV PCR was positive with 6.22x10^2 copies of DNA/10^5 cells without evidence of CMV disease, and the patient was started on valganciclovir preventive therapy. After the cancellation of immunosuppression (five months after transplantation), the patient's clinical course had worsened - appeared frequent watery stool, abdominal cramps, weight loss. Colonoscopy with colon biopsy was performed, which showed the presence of ulcerative colitis. MV, EBV, human papillomavirus were negative, herpes simplex viruses 1 and 2 were positive in biopsy samples. Serum PCR CMV was not detected. He was started on antibiotics and antiviral therapy without any improvement. At D+270 PCR analysis showed that serum CMV was detectable, for which he again started treatment with valganciclovir 450 mg/day for 2 weeks. A gradual decrease in the number of leukocytes, platelets and hemoglobin level has been observed and watery liquid stool persisted. Differential diagnosis was conducted between CMV - enterocolitis and chronic intestinal GVHD.

Biopsies from repeated colonoscopy showed positive PCR CMV. For increased watery stool, febrile fever, epistaxis due to cytopenia, patient received antibacterial and thrombocyte replacement therapy, G-CSF. But despite that, cytopenia persisted. Monitoring PCR CMV in the blood showed low viral load ($4.26x10^2$ copies of DNA/10^5 cells). As possible causes of pancytopenia were considered recurrence of ALL, bone marrow failure, viral (CMV) infection. The patient's peripheral blood smear confirmed pancytopenia without any abnormal cells in bone marrow.
Results: Based on these findings, diagnosis of CMV infection affecting the small intestine and colon was made and IV ganciclovir 10 mg/kg was started (despite of cytopenia - WBC $1.6*10^9$/l, Hb 86 g/l, Pl $22*10^9$/l). The patient showed gradually improvement in pancytopenia, fever and frequency of stools. Quantitative PCR for CMV was repeated 2 weeks later and it became negative.
Summary/Conclusion: CMV infection could induce sustained and irreversible pancytopenia, despite normal findings in bone marrow aspiration. The pathogenesis is likely multifactorial, with both a central and peripheral effect. Several mechanisms have been proposed to explain the effect of CMV on human hematopoietic function. One indicates direct effect of CMV on bone marrow cells leading to cellular injury. Also alteration of accessory cell function by inducing the production of inhibitory cytokines resulting in a decreased production of hematopoietic factors or by altering cell surface adhesion molecule expression. Immunological mechanisms can be involved. The treatment of CMV viremia is not inconsequential and requires a close surveillance because first-line anti-CMV agents such as gancyclovir can further cause myelosuppression which may lead to superadded bacterial or fungal infection.

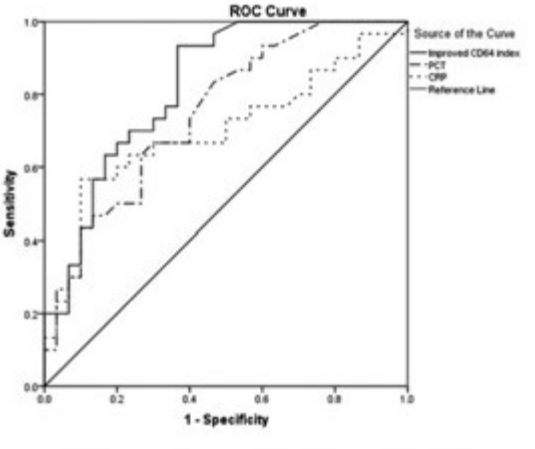
PB2063

THE DETECTION METHOD OF PERIPHERAL BLOOD CD64 INDEX IN PATIENTS WITH HEMATOLOGICAL MALIGNANCY

S. Yuxi*, W. liru

Fu-xing Hospital, Capital Medical University, 100038 - Beijing, China, Fu-xing Hospital, Capital Medical University - Beijing, China, Beijing, China

Background: Peripheral blood CD64 index contribute to diagnosing clinical bacterial infection and early sepsis, but some patients with hematologic malignancies in the process of CD64 index detection are interfered with abnormal cells, which caused mature neutrophils group-dividing difficult. Thus, it affects mature neutrophil CD64 index detection, leading to error or not detected. The application of CD64 index in blood system disease was affected.



ROC curve of Improved CD64 index, CRP, PCT.

Figure 1.

Aims: This cohort study include the patients with hematologic malignancies who are in the process of CD64 index test interference and influence the test results by abnormal cells. The antibody of CD45, CD15, CD10 was added to the original kit, the neutrophilic granulocytes were more accurately divided in order to measuring the improved CD64 index.
Methods: Try to improve the detection method of CD64 index of patients with hematologic malignancies.Comparing the diagnostic efficacy of improved CD64 index, PCT and CRP for sepsis with non-improved.
Results: The CD64 index detection was performed on patients with malignant hematologic disease with suspicious infection in the hematology ward. Results of 60 samples were disturbed by abnormal cells during the detection process. the CD64 index was higher than that in the non-sepsis group (P<0.0001). The improved CD64 index was better for sepsis diagnose than the before improved CD64 index, PCT and CRP.
Summary/Conclusion: For patients with malignant hematopathy who are disturbed by abnormal cells during the detection of CD64 index, the detection rate and the accuracy of detection can be improved by adding antibody.

PB2064

PERIOSTITIS - A RARE COMPLICATION OF VORICONAZOLE

S. Sen[1,*], S. Tulpule[2], S. Sivadasan[1], T. Singhal[1], K. Mullanfiroze[1]

[1]Dept of Paediatric Oncology & BMT, [2]Dept of Oncology & BMT, Kokilaben Dhirubhai Ambani Hospital, Mumbai, India

Background: Voriconazole is commonly used antifungal agent used in paediatric oncology patients for prophylaxis and treatment of fungal infections. We report here on one of our post transplant patients who presented with acute bone pain over the tibia.
Aims: To describe a uncommon complication of Voriconaole use that can be confused with relapse of disease.
Methods: A 6 year old boy with relapsed B cell ALL had a successful matched sibling donor transplant. Post transplant, patient was given presumptive therapy with liposomal amphotericin as his galactomannan screen was positive. Later his antifungal therapy was switched to voriconazole and he was discharged on the same. Voriconazole levels were monitored and kept at a therapeutic level. On Day + 45 patient presented with severe leg pain and difficulty in walking. There were no neurological findings and a X Ray of the legs were normal. Suspecting a relapse, a bone marrow aspiration and biopsy was done which showed no evidence of disease recurrence with MRD being negative and 100% donor chimerism. The pain increased in severity to an extent that the child stopped walking. A MRI scan was done which only showed periosteal thickening suggestive of mild periostitis over the tibia. Differential diagnosis of leukemic infiltration, osteomyelitis and drug induced periostitis was considered. As we had ruled out a relapse with a bone marrow examination and all inflammatory markers were negative, we deduced that drug induced periostitis was the most likely cause for the symptoms. Discontinuation of voriconazole led to complete resolution of pain within 48 hours.
Results: At one year post transplant, patient continued to be in remission and pain free.
Summary/Conclusion: Painful periostitis is a rare complication of long term voriconazole therapy which has only been recently reported in literature. Fluorosis and promotion of bone formation by osteoblast stimulation is the the proposed mechanism for voriconazole induced periostitis. Increased awareness of this rare condition can lead early correct diagnosis.

PB2065

PHAGOCYTOSIS BY PERIPHERAL BLOOD MONOCYTES IN A CHILD WİTH EBV ASSOCIATED LYMPHOMATOID GRANULOMATOSIS

S. Secil[1], S. Aytac[1,*], D. Cagdas[2], M. Cetin[1], F. Gumruk[1]

[1]Department of Child Health and Diseases, Hematology Unit, Hacettepe University Faculty of Medicine, [2]Department of Child Health and Diseases, Immunology Unit, Hacettepe University, Faculty of Medicine, Ankara, Turkey

Background: Lymphomatoid granulomatosis is a rare, Epstein Barr Virus (EBV) associated systemic angiodestructive disorder which is considered a part of the spectrum of lymphoproliferative disorders. It usually presents in adulthood and uncommon in children. The incidence is higher in patients with immunodeficiency disorder. Pulmonary involvement occurs in over 90% cases and most of the time respiratory symptoms are initial sign of manifestation. The most common secondary HLH cause in pediatric population is EBV associated HLH.
Aims: Herein, we present a peripheral hemophagocytosis in a child with EBV associated lymphomatoid granulomatosis. Phagocytosis by peripheral blood monocytes occasionally be found on peripheral smears which may alert the physcian for evaluating bone marrow.
Methods: Case: A sixteen year-old female with an initial dignosis of sarcoidosis was admitted to the hospital with a complaints of cough, fever and fatigue. On her physical examination there were ecchymoses both at her arms and legs and pallor with hepatosplenomegaly. Laboratory evaluation revealed Hb:6,9g/dl, Hct:20,8%, platelet:$64x10^9$/L, WBC:$0.9x10^9$/L and examination of the peripheral blood by light microscopy revealed striking phagocytic activity by the monocytes with a differentiation of neu-

trophil%62, monocyte%12, lymphocyte%18, stab neutrophil%8 (figure 1). Her ferritin level was found to be increased at 963,6 ng/mL. Bone marrow examination showed prominent hemophagocytic histiocytes (HS), which is consistent with HLH. She received chemotherapy according to the HLH-2004 protocol, which includes etoposide, steroids, cyclosporin and ganciclovir as an antiviral treatment. In her follow up her pulmonary symptoms did not resolve and due to suspicions related to the previos diagnosis of sarcoidosis, a new Contrast Enhanced CT scan was done which showed pleural effusion at left hemithorax, bilateral mediastinal, paratracheal, subcarinal, hilar lymphadenopathy and boundless, centrilobular nodular opacities in both lungs. The EBV DNA in blood was 4208×10^3copy/mL. A previous lung biopsy was reevaluated and found that EBER was positive in granulamatous reaction which is compatible with lymphomatoid granulomatosis.

Results: The patient was treated with anti-CD20 immunotherapy (Rituximab, 375 mg/m^2 intravenous infusion, four doses over a four week period). She got third doses of Rituximab, pulmonary lesions and HFS were resolved.

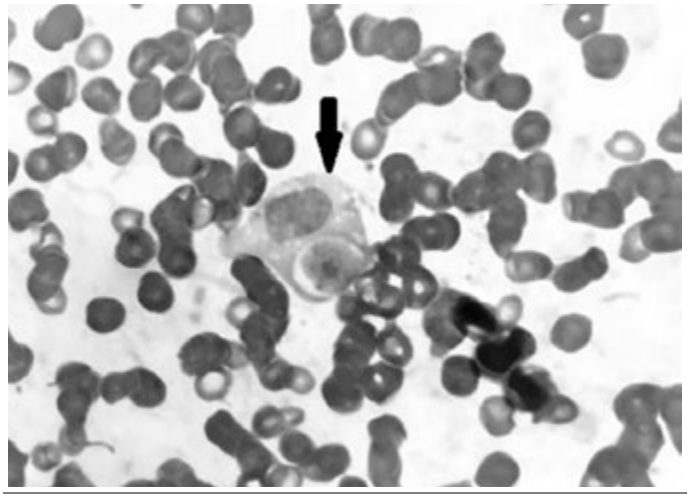


Figure 1.

Summary/Conclusion: In our case EBV seems to be the responsible factor for both hemophagocytosis and lymphomatoid granulomatosis. Although the phagocytic activity of monocytes is well known it was occasionally find in the peripheral blood smear, in this case the interesting fact is that phagocytic activity is observed in the peripheral smear and bone marrow examination.

UNUSUAL CLINICAL PRESENTATION OF CANDIDA TROPICALIS INFECTION IN A AML NEUTROPENIC PATIENT

F. Cuellar-Ambrosi[1,*], M. Monsalve[1], I.M. Trompa[2], G. Gaviria Cardona[1], I.F. Vega-Gonzalez[3], O.A. Osorio[4]

[1]Hematology, [2]Infectology, Clinica Leon XIIII, [3]Radiology, [4]Nuclear Medicine, Clinica Las Americas, Medellin, Colombia

Background: Invasive fungal infections (IFIs) cause considerable morbidity and mortality in patients with hematological neoplasia. Physicians frequently rely on a constellation of clinical signs, imaging, cultures, histopathology to establish a diagnosis and a suitable follow-up.

Aims: We presente a 20 y-o boy with AML who developed severe systemic *candida tropicalis* infection during induction chemotherapy neutropenia period and detected by cultures and PET CT.

Methods: This report is from the Hematology and HSCT Service of the Clinica Leon XIII - IPS Universidad de Antioquia in Medellin - Colombia. An unusually descriptive case of IFI by *candida tropicalis* in order to highlight some diagnostic clues and follow-up support.

Results: A 20 y-o young man presented with AML-M2, CD3,CD117, CD34CD45d,HLADR,CD15, all (+), MPOd 100%. PML-RARA (-). Current 7+3 protocol was started. Standard prophylaxis with acyclovir and fluconazole was done. At day +15 neutropenic fever appeared and some days after hemocultures yielded *candida tropicalis.* Concomitantly, disseminated absceded subcutaneous skin nodules were observed. In cultures from these abscess *candida tropicalis* grew again. PET CT revealed disseminated nodular lesions, *photo.* Amphotericine deoxyclate and high dose fluconazole were started. On the other hand, the patient reached leukemia complete remission. One month later his clinical condition was stable with nodular skin lesions clinically resolved, except the persistent abscess in the pericardium as shown on PET CT. Successful surgical drain of the persistent pericardial abscess was done. HiDAC consolidations were followed without candida reactivation.

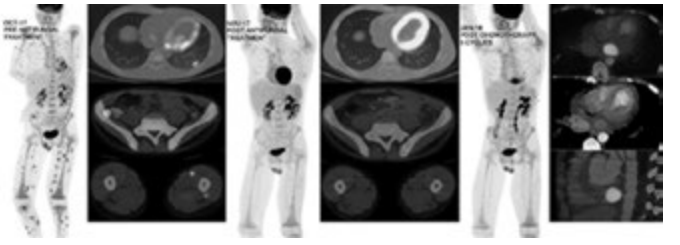

Figure 1.

Summary/Conclusion: IFIs are common during treatment of hematological malignancies. Diagnostic methods some times are inconclusive to evaluate their clinical extension and for monitoring evolution. We present here a young man with chemotherapy induced neutropenia who developed disseminated *candida tropicalis* infection with unusual definite extension and the monitoring of response by serial PET CT.

PB2067

PRIMARY ANTIFUNGAL PROPHYLAXIS WITH MICAFUNGIN IN HEMATOLOGICAL MALIGNANCIES: A SINGLE CENTER EXPERIENCE

M. Porrazzo*, M. Piedimonte, A. Campagna, G. Galassi, S. Pelliccia, E. Conte, A. Ferrari, A. Tafuri

Hematology, Sapienza, Rome, Rome, Italy

Background: Micafungin is a clinically important echinocandin antifungal drug, recently approved as prophylaxis treatment in patients undergoing allogeneic transplantation and in those undergoing prolonged neutropenia (>10 days). The use and the role of micafungin however prophylaxis is still questionable in term of comparison with azole compounds and on the potential selective pressure of micafungin toward resistant fungi. Furthermore, the frequency of breakthrough invasive fungal diseases (IFI) during echinocandin therapy is unclear.

Aims: To evaluate the frequency of breakthrough IFI in a single center experience of hematological malignancies treated with primary antifungal prophylaxis by micafungin.

Methods: To evaluate retrospectively the use of micafungin in 11 adult hematological patients treated at our institution and characterized by high and intermediate risk of infections for development of IFI according to the latest NCCN Guidelines (table 1).

Table 1. Patients characteristics.

Median age, years (range)	60 (33-74)
Female: Male	1:10
Patients at high risk for IFD n. (%) - Induction/consolidation chemotherapy for acute leukemia - Severe Aplastic Anemia - AML during other treatments	6/11 (54.5%) 3/11 (27%) 1/11 (9%) 2/11 (18%)
Patients at intermediate risk for IFD n. (%) - ASCT with severe mucositis	5/11 (45%)
History of previous infections - Bacterial - Viral - Fungal	3/11 (27%) 2/3 (67%) 1/3 (33%) 0/3
CIRS SCORE - < 6 - > 6	9/11 (82%) 2/11 (18%)
Days of neutropenia at micafungin discontinuation, median (interquartile range)	9 (6-13)

Results: All patients received prophylactic micafungin at 50 mg/day during neutropenia until neutrophils recovery or breakthrough IFI. The median of the days of neutropenia at micafungin discontinuation was nine. Febrile neutropenic patients with suspected IFI underwent an infective work up including serum galactomannan and/or bronchoalveolar lavages (BAL), CT scan and multiple samplings of blood cultures. IFI occurred in three patients affected by high risk of IFI, with two proven IFI, Aspergillus and Mucor

species, respectively (table 2). All patients had a grade IV neutropenia and the IFI occurred respectively after 30, 24 and 11 days of neutropenia from the first administration of micafungin. We observed two lung infections, with sepsis in a patient affected by severe aplastic anaemia and a CNS involvement in an AML patient, respectively. The third patients with AML secondary to myelodysplastic syndrome developed a probable liver fungal infection revealed by CT scan. All patients were treated empirically with liposomal amphotericin B followed by voriconazole: two died of IFI after 25 and 23 days, the third died because of refractory leukemia. No IFI were documented in the five patients at intermediate risk receiving micafungin prophylaxis, while the other three high-risk patients developed a fungal infection several months after micafungin discontinuation.
Summary/Conclusion: In our experience, micafungin was active as profilaxis treatment in intermediate risk patients. Whereas a feeble approach has been shown in patients with high risk of IFI. We suggest therefore evaluating in a larger series of patients this approach to clarify which patients may take advantage of micafungin prophylaxis

Iron metabolism, deficiency and overload

PB2068

SOLUBLE TRANSFERRIN RECEPTOR LEVEL AS PREDICTOR OF IRON OVERLOAD IN PATIENTS WITH B-THALASSEMIA AND SICKLE CELL DISEASE

A. El-Beshlawy[1,*], A. Abdel-Salam[1], M. El-Tagui[1], M. Farhan[2], M. Ramadan[3], W. Mouthanna Saeed Kassim[4], M. El-Ghamrawy[1]

[1]Pediatric Hematology & BMT Unit, [2]Clinical Pathology Department, [3]Faculty of Medicine, Cairo University, Cairo, Egypt, [4]Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt

Background: Soluble transferrin receptor (sTfR) is one of the main regulators of cellular iron homeostasis, and is an emerging diagnostic tool of iron status.
Aims: To investigate the diagnostic value of sTfR as compared to serum ferritin (SF) in assessment of iron overload expressed as liver iron concentration (LIC) measured by magnetic resonance imaging (MRI) in patients with β-thalassemia major (BTM) and sickle cell disease (SCD).
Methods: Eighty transfusion dependent patients (64 BTM and 16 SCD) with a mean age of 10.8±4.5 years were recruited. Steady state SF and sTfR levels were assessed quantitatively by enzyme linked immunoassay (ELISA). LIC values, within 6 months' duration, as identified by quantitative MRI of hepatic iron stores as a signal intensity ratio method based on T1 and T2* contrast imaging without gadolinium were retrieved. We categorized iron overload status in our patients into 2 subgroups: group A; 52 patients with LIC >7mg/g dw, and group B; 28 patients with LIC <7mg/g dw. Informed consent was obtained from patients' legal guardians before enrollment. The study protocol was approved by Cairo University Research Ethics Committee.
Results: Mean sTfR, SF and LIC of studied group (n=80) were 121 nmol/L, 2478 ng/ml and 18.6 mg/g dw respectively. BTM and SCD patients had comparable mean sTfR and SF (p>0.05 for both) but LIC was significantly higher in BTM group (p<0.001). Group A had significantly higher median sTfR and SF compared to group B (p=0.026 and 0.003 respectively). However, sTfR did not correlate with SF or LIC (p=0.273, 0.725 respectively). A positive correlation was evident between SF and LIC (r=0.49, p=0.001). Both sTfR and SF were good predictors of iron overload at certain cutoff levels; ROC curve of sTfR and SF at cutoff values of 110.4 nmol/L and 1220 ng/ml respectively demonstrated a sensitivity of 90.6%, specificity 62.5% for both (p 0.05). Using *Cohen's kappa testing*, agreement between serum sTfR at a level of 110.4 nmol/L and LIC was evident (p=0.001); but this significance was lost at sTfR values ≥133.3 nmol/L. Significant agreement between SF and LIC were evident at both values of 1220 ng/ml and 1591.5ng/mL and higher (p=0.001 and 0.014 respectively).
Summary/Conclusion: sTfR was a valuable quantitative assay of iron overload in children with BTM and SCD. Both sTfR and SF could accurately predict hepatic iron overload among our patients at certain cutoff values. However, the overall accuracy and agreement of sTfR with LIC was lost at high serum values.

PB2069

THE INCREASING FERRITIN SERUM LEVEL AND OVERALL SURVIVAL IN PATIENTS WITH MALIGNANT LYMPHOMAS

T. Babaeva*, T. Pospelova, O. Seregina

Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: It is known, that extracellular ferritin takes part in mechanisms of neoplasm progression in solid cancer, and can stimulate proliferation of malignant cells lines. Similarly, the ferritin serum level correlates with tumor mass volume and tumor activity in patients with hematological malignancies, such as malignant lymphoma and acute leukemia. On the other hand, the normalization of ferritin serum level in remission has proved the clinical value of ferritin for initial assessment and therapy response evaluation, especially in patients with malignant lymphomas.
Aims: Was to evaluate the increasing ferritin serum level in newly diagnosed patients with malignant lymphomas.
Methods: A total of 98 patients with malignant lymphoma, including 72 patients with non-Hodgkin's lymphoma (73,5%) and 26 patients with Hodgkin's lymphoma have been examined in our study. 84,7% of the patients with non-Hodgkin's lymphomas have advanced staged of disease (III-IV). All patients have received 4-6 courses of chemotherapy. The ferritin serum level was detected by Enzyme-linked Immunosorbent Assay (ELISA).

Results: the overall survival was evaluated in two groups of newly diagnosed patients: in first group of patients (n=43) the ferritin serum level was <350ng/ml, in another group of patients (n=55) the ferritin serum level was >350 ng/ml. The median survival in patients with ferritin level >350ng/ml was lower (40 months; p=0,004) than in patients with normal level of ferritin at onset of disease - in this group of patients the median survival has not been reached. The initial level of hemoglobin at the onset of disease was used as the reference marker of poor prognosis. The overall survival (OS) in the group of patients with normal level of hemoglobin (>120g/L) has not reached the median of survival, whereas patients with anemia (hemoglobin 120 g/L) has tended to deteriorate the overall survival (OS) - the median of survival was 40 months (p=0,007). Besides that, the low level of hemoglobin, correlates with significant increasing the mortality risk (Odds ratio (OR)-6,333; confidence interval (CI) – 95%; 2,152-18,638; p 0,05). Patients with high ferritin serum level at the onset of disease also has poorer results of survival and higher risk of mortality (OR 8,122; CI-95%, 1,764-37,396; p 0,05) by comparison with the group of newly diagnosed patients with ferritin serum level 350ng/ml.
Summary/Conclusion: These findings allow to conclude the patients with hyperferritinemia at the onset of disease in the group of patients with poor prognosis and lower overall survival. The high ferritin serum level in patients without prior blood transfusion should consider as a significant marker of poor prognosis. The analysis of ferrokinetics in patients with lymphomas before starting the chemotherapy make it possible to use preventive approach for combining groups with poor prognosis and elimination of negative factors.

PB2070

DIFFERENTIATION OF IRON DEFICIENCY ANEMIA AND THALESSEMIA TRAIT IN CHILDREN WITH MICROCYTIC HYPOCHROMIC ANEMIA

G. Aydogan*, S. Keskin, N. Ozdemir, F. Akici, Z. Salcioglu, C. Bayram, E. Pasli, E. Yilmaz, A. Aycicek, T.N. Tahtakesen, G. Ersoy

Pediatric Hematology, Kanuni Sultan Suleyman Education And Research Hospital, Istanbul, Turkey

Background: Microcytic anemia is defined as anemia with a low mean corpuscular volume (MCV) for age, race, and sex. The most common causes of microcytic anemia in children are iron deficiency and thalassemia. Iron deficiency and thalassemia are characterized by decreased hemoglobin production, due to insufficient availability of heme or globin, respectively and both cause hypochromic microcytic anemia. Iron deficiency is frequently seen in parts of the world where nutrition is inadequate and the socioecomic status is low. Thalassemias are common in the Mediterranean region. Thalassemia trait may be identified as an incidental finding. Differentiation and detection of coexistence is essential for genetic counselling and to set a treatment plan on the basis of etiology.
Aims: The aim of the study was to characterise the frequency of iron deficiency anemia (IDA) and thalassemia trait among children who presented with microcytic anemia in our pediatric hematology clinic.
Methods: Data were available for 200 children (6 months-18 years) attending the outpatient pediatric hematology clinic between August 2013-July 2014. Screening for iron deficiency was done by analysing serum ferritin, iron and iron binding capasity. Haemoglobin variants were diagnosed by HPLC or capillary electrophoresis and molecular methods.
Results: Of the 200 enrolled, 93 were female (46.5%) and 107 were male (53.5%). Fifty-three children were <2 years of age (26.5%), 52 (26%) between 2-4 years, 56 (28%) between 5-11 years and 39 (19.5%) were >12 years old. One-hundred-fiftyfour had IDA (77%), 27 had thalassemia trait (13.5%), and in 11 both conditions co-existed. Eight of the thalassemia trait patients were found to have an alpha-thallesemia gene mutation, in 3 of these there was also IDA. RBC, MCV, Mentzer index (MI), serum iron, total iron binding capacity, ferritin were significantly different between IDA and thalassemia trait patients (p<0.001) however RDW was not different between the 2 groups (p>0.05). Sensitivity and specifity of MI for detection of thalassemia trait 100% and 69.4% respectively. The positive and negative predictive values of MI in diagnosing thalassemia trait were 36.6 and 100%. In patients with co-existing IDA and thalassemia trait; MI had a sensitivity of 90.9%, specifity of 69.4%, pozitive predictive value of 17.5% and a negative predictor value of 99.7%.
Summary/Conclusion: The differentiation between βTT and IDA, requires Hb A2 estimation by Hb electrophoresis, examination of a peripheral blood film, serum ferritin, iron, TIBC, and transferrin saturation. The requirement of simple distinguishing parameters between IDA and thalassemia trait in a child presenting with hypochromic microcytic is needed as several studies have shown the effect of coexistence of IDA on HbA2 synthesis resulting in confusing levels of HbA2 in thalessemia. Hemoglobin electrophoresis is also not helpful in patients with alpha- thalassemia trait.

PB2071

PARENTERAL IRON THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: AUDIT ON A SINGLE CENTRE CLINICAL PRACTICE

S. Lovato*

Postgraduate, London North West University Healthcare NHS Trust, London, United Kingdom

Background: Iron deficiency is common in Inflammatory Bowel Diseases (IBD), unfortunately oral iron supplements are often poorly tolerated and parenteral iron is used instead. National and international guidelines establish the best practice regarding diagnosis of iron deficiency, indication for parenteral iron therapy and follow up recommendations. Regular audits are an effective tool to ensure the guidelines are followed and to improve local practice.
Aims: The aim of the study was to compare the parenteral iron therapy practice in Ealing hospital with the national and international standards. We looked at the blood test used to diagnose iron deficiency: haemoglobin, ferritin and transferrin saturation if ferritin normal or high. We also evaluated the appropriateness of parenteral iron therapy according to the guidelines; first line parenteral therapy is indicated for haemoglobin levels lower than 100g/l, IV iron is used as second line in patients not responsive or intolerant to oral iron. Follow up should be performed at least four weeks after the infusion and within three monthsand should include haemoglobin and ferritin; in case of iron deficiency the patient should be prescribed further iron therapy.
Methods: Parenteral iron prescriptions for patients with IBD were identified. The hospital informatics system was used to retrieve clinical data and blood test results. Twelve months data were taken in account.
Results: We identified 19 prescriptions for 15 patients. One patient, who had 3 prescriptions, had blood test done with an unusual pattern, she was on iron infusion maintenance every four months and she had follow up blood tests done two weeks after the infusion, too early for follow up and too old for diagnosis of iron deficiency at the time of the iron infusion. In the remaining 16 cases iron deficiency was confirmed in the months before by FBC and ferritin; transferrin saturation was performed in all 4 cases with normal ferritin. Of the 19 prescription 15 were definitely appropriate; in 4 cases appropriateness was not evaluable (3 due to lack of recent blood tests, in 1 case haemoglobin was >100g/L, too high to justify IV iron as first line therapy, and there was no clinical information on previous oral iron therapy). Follow up was done in 18 cases but timing was variable. Only in 8 cases follow up was arranged within 3 months as suggested by the guidelines, in 5 cases the follow up was arranged earlier and in the remaining 5 later. In 4 cases the follow up was not acted upon, the patients were still iron deficient but no further iron therapy was prescribed.
Summary/Conclusion: The results were discussed with the IBD team to create an action plan to improve patients' care. Diagnosis was good and appropriateness wad acceptable, the only patient who had an abnormal pattern of blood tests will be contacted to modify how therapy is given and monitored. Follow up practice was the main issue, this was due to lack of dedicated specialist nurse who could organise day unit appointment and follow up. The clinician seeing the patient and prescribing parenteral iron will take responsibility of ensuring that iron deficiency is confirmed with recent blood tests and appropriate follow up, either with an appointment in the IBD clinic or through the General Practitioner, is organised. Once applied these changes the audit should be repeated in one year to ensure the changes improved the compliance with international guidelines.

PB2072

WHICH IS THE ETIOLOGY OF BREATH HOLDING SPELL? CARDIAC CONTRACTION OR IRON DEFICIENCY ANEMIA

S. Akarsu[1,*], T. Kasar[2]

[1]University of Firat, Faculty of Medicine, Pediatric Haematology, Elazig, [2]University of Ordu, Faculty of Medicine, Pediatric Cardiology, Ordu, Turkey

Background: Breath-holding spell (BHS) is a prevalent, nonepileptic, recurrent, potentially frightening early childhood disease with varying clinical manifestations. In addition to underlying genetic predisposition, dysregulation of central nervous system (CNS) is responsible for BHS. Autonomic dysfunction which leads to cardiac arrest, and cerebral anoxia, and increased

vagal tonus play roles in its pathogenesis. It may accompany iron deficiency anemia (IDA). In cases with BHS, increase in corrected QT (QTc), and QTc dispersion (QTcd) which are electrocardiographic (ECG) reflection of regional differences in myocardial repolarization have been demonstrated.
Aims: In our study, we determined whether BHS develops as a result of dysrhytmia secondary to abnormal ventricular depolarization inherent to the disease, or as an outcome of IDA.
Methods: Study groups were formulated prospectively. BHS-IDA group consisted of cyanotic children aged between 9 and 60 months. The cases were evaluated in 3 groups as follows: Group 1 (Group BHS-IDA, n: 12), Group 2 (Group IDA without BHS, n: 34), Group 3 (Healthy control group, n: 26). ECGs were evaluated by the same pediatric cardiologist at one session. The difference between the longest, and the shortest QTc intervals was accepted as QTcd. Cases in all three groups were compared as for QTc, and QTcd values. Statistically analysis was performed using Student's *t*, and Mann-Whitney *U* tests, and $p<0.05$ was accepted as the level of statistical significance.
Results: QTc intervals were 412.5±19.1 ms in Groups 1, 394.4±27.1 ms in Group 2, and 395.8±20.2 ms in Group 3. QTcd intervals in children diagnosed as BHS-IDA 12.0±6.5 ms, IDA 16.4±10.5 ms, and healthy control group 27.6±9.0 ms were as indicated ($p>0.05$).
Summary/Conclusion: IDA may affect cardiac, and nervous system which play an important role in changing autonomic nervous system balance. It induces hypoxia which leads to dysrhytmia. However in cases with BHS, ventricular repolarization which develops as a result of autonomic dysregulation, and increased vagal stimulation may differ.

PB2073

AN OLD CANDY IN A NEW WRAPPER! NUTRITIONAL DEFICIENCY IN SAMPLES OBTAINED FOR HAEMOGLOBINOPATHY SCREENING

A. Memon[1,*], I. siddiqui[2], N. ali[1]

[1]Department of Pathology & Laboratory Medicine, [2]Aga Khan University Hospital, karachi, Pakistan

Background: Anemia is a major health concern globally, yet devastating for the developing countries. Iron deficiency considers contributing 70% of total nutritional deficiencies and 30% are said to be due to vitamin B12/ folate and deficiency of other micronutrients. Iron deficiency and megaloblastic anemia cause variations in haemoglobin A_2 levels which may lead to misdiagnosis. It has a financial and psychological implication to that person. True prevalence of iron or vitamin B12 / folate deficiency is uncertain in our population.
Aims: This study aim to determine iron and vitamin B12 / folate deficiency in samples received for haemoglobinopathy screening.
Methods: Retrospective review of first 200 chromatograms and peripheral blood film of samples received for haemoglobinopathy screen by HPLC (High performance liquid chromatography) during the February 2016 at Section of Haematology, Department of Pathology & Laboratory Medicine, Aga Khan University Hospital Karachi. Cases with haemoglobinopathies and with alternative diagnosis like malaria, leukemia and pancytopenia were excluded from this study.
Results: Total 200 consecutive chromatograms and peripheral blood films of samples were reviewed retrospectively. Out of these 200 cases 47% cases, (n=94) showed nutritional deficiency with female to male ratio of 2:1 and mean age of 13 years. Among these 47% cases, 44.5% cases (n=89) showed iron deficiency with 5% suspicion of suppressed haemoglobin A_2 levels. Vitamin B12/ folate deficiency was found in 2.5% (n=5) of cases with raised haemoglobin A_2 levels.
Summary/Conclusion: Nutritional deficiency was found in 47% cases in current study. This is an ongoing study, further data will be included while completion of a study period. Authors recommend treating an underlying nutritional deficiency prior to haemoglobinopathy screen.

PB2074

AUTOIMMUNE IRON DEFICIENCY ANEMIA, IS IT REAL? CASE REPORT

N. Vaynyunskaya*

Pediatric hematology, Saint-Petersburg State Children Hospital [1], Saint-Petersburg, Russian Federation

Background: Revalence of iron deficiency (IDA) are staggering: 2 billion people, *i.e.* more than 30% of the world's population suffer from that. IDA is one of the most studied pathological condition. It is "the most grateful anemia" and after normalization of diet, adequate ferrotherapy and treatment of the digestive tract relapses should not happens. The most difficult is to understand causes of recurrence IDA in previously examined and treated patients with no obvious reason.
Aims: Our aim is to describe the clinical case of recurrent iron-deficiency anemia presumably autoimmune etiology in 17 year old girl.
Methods: Determination of specific antibodies to human-ferritin by the method of detection of lupus anticoagulant in patients with prolonged APTT. Ferritin of the patient was 0,008ng/ml.The ferrinin of the control sample was 171ng/ml. After mixing in equal proportions plasma of the patient and control, incubation for two hours ,the level of ferritin in the control sample decreased from 171 to 51ng/ ml. We do not have in Russia Anti-Ferritin antibody.
Results: The patient had history of 5 years long IDA. All possible examinations were made, there was no bleeding, malnutrition or hereditary IDA. At the time of admission her blood test was - HB 47g/l, MCV 54,Ret-Hb-14%. As we have found "anti ferritin" antibody by our original method it was chosen intravenous immunoglobulin(IVIG) at a dose of 2mg/kg for treatment. Simultaneously with the treatment IVIG our patient received iron supplementation. The treatment was successful. On day 14, the HB level increased to 106g/l. One month after the treatment HB was 126g/l, erythrocytes-4,3 x10/12/l, MCV 83, 346 MCHC, MCH 28, Ret-Hb -29%, ferritin 146ng/ml.
Summary/Conclusion: There are a lot of immune disease in our century. We can not forget about it when we treat patients with reccurent IDA. Sometimes anti ferritin antibodies may be very useful. And if there are no anti ferritin antibodies in your countries we offer to make the incubation with control as we did.

Myelodysplastic syndromes – Biology & Translational Research

HLA-G GENE AND PROTEIN EXPRESSION IN PATIENTS WITH PRIMARY MYELODYSPLASTIC SYNDROME

S. Giannouli[1,*], A. Nezos[2], E. Zintzaras[3], A. Papageorgiou[4], K. Kampas[4], I. Stergiou[4], M. Voulgarelis[4]

[12nd Department of Internal Medicine, [2]Department of Physiology, National and Kapodistrian University of Athens, Athens, [3]Department of Biomathematics, University of Thessaly School of Medicine, Larissa, [4]Department of Pathophysiology, National and Kapodistrian University of Athens, Athens, Greece

Background: In myelodysplastic syndromes (MDS) deregulation of immune effectors pathogenetically drives abnormal haemopoiesis and enhanced leukemic propensity. Human leukocyte antigen G (HLA-G) is a nonclassical MHC class I antigen, regularly not expressed in normal tissues except in trophoblasts from early gestation placentas and other immune-privileged tissues. Evidence for HLA-G silencing by a DNA methylation process has been reported. Interestingly, the use of demethylating agents such as 5-azacytidine further demonstrated that the repression of HLA-G gene activity in cultured various cell lines is reversed by demethylating treatment. HLA-G primary transcript generates seven alternative mRNAs that encode membrane-bound HLA-G1, -G2, -G3, -G4 and soluble HLA-G5,-G6 and –G7 isoforms. HLA-G has a direct inhibitory effect on the cytolytic activity of NK cells, cytotoxic T lymphocytes and is implicated in the induction of Foxp3-regulatory T cells. Therefore, HLA-G possesses immune tolerogenic activity with potential implications in antitumor immune responses.
Aims: In order to investigate potential implication of HLA-G in immune deregulation underlying MDS pathogenesis and evolution we studied HLA-G gene and protein expression in CD34 cells of patients with primary MDS.

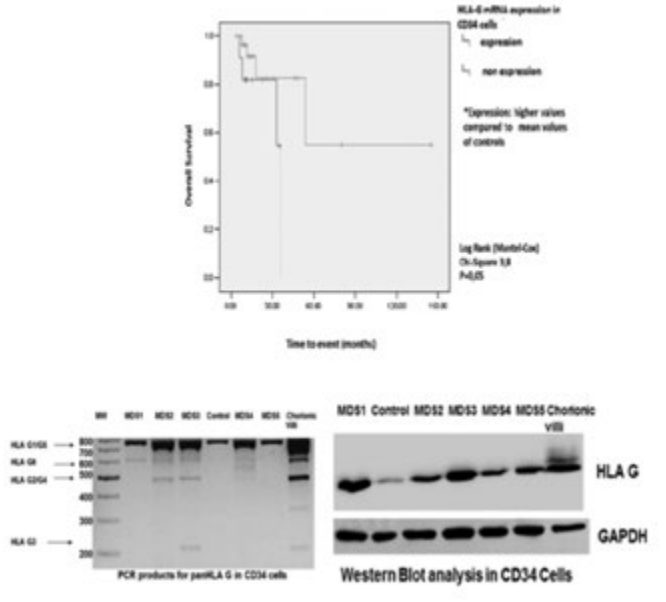

Figure 1.

Methods: Real Time PCR for HLA-G mRNA expression was performed in CD34 bone marrow (BM) cells derived from 35 primary untreated MDS patients of all subtypes, 7 patients with high-grade Non Hodgkin Lymphoma without BM involvement, as well as first trimester trophoblasts from 2 donors served as controls. CD34 BM HLA-G protein levels were evaluated by Western blot in 10 study participants and plasma HLA-G protein levels were evaluated by ELISA in 22 MDS samples and 17 apparently healthy age/sex matched controls. Canonical variate analysis (CVA) was used to discriminate MDS subtypes using a set of several well established laboratory parameters, as well as the HLA-G expression in CD34+ cells. The Kaplan–Meier method was used for calculation of survival probabilities and the Log-rank test for comparison of survival curves between expression levels of HLA-G. Cox regression was used for Overall Survival (OS).
Results: Increased HLA-G mRNA and protein expression was observed in CD34 cells from MDS patients compared to controls (p=0.04 and p=0.0095, respectively). Plasma HLA-G levels were significantly higher in MDS patients compared to controls (p=0.0008). A distinct pattern of expression of various HLA-G mRNA isoforms was noted between MDS patients and controls. HLA G1/G5 was the commonest isoform expressed in CD34 cells, but other less common isoforms namely HLA-G2/-G4,-G3, and –G6 were also expressed. Interestingly, the CVA revealed that the major parameters that play a role in discrimination of the three major MDS subtypes (RCUD, RCMD and RAEBs), were not only the expected parameters of WPSS and percentage of blasts, but also the HLA-G mRNA expression in CD34 cells. OS curves of MDS with HLA-G mRNA overexpression differed significantly during follow-up, compared to MDS patients without expression (p=0.05).
Summary/Conclusion: Given the immune inhibitory properties of the HLA-G molecule, its increased expression in MDS CD34 cells may implicate the mechanisms of resistance or escape to immune surveillance contributing to MDS evolution and prognosis. Moreover, in the era of demethylating treatment the finding of HLA-G expression by MDS CD34 cells is of specific clinical interest.

PB2076

GENE EXPRESSION AND EPIGENETIC PROFILING SEPARATES CASES WITH DIC(1;7)(Q10;P10) FROM T-MDS/AML

A.G. Lema Fernandez[1,*], B. Crescenzi[1], V. Pierini[1], V. Di Battista[1], G. Barba[1], F. Pellanera[1], D. Di Giacomo[1], R. Piazza[2], E. Adelman[3], M.E. Figueroa[4], C. Mecucci[1]

[1]Department of Medicine, University of Perugia, Perugia, [2]School of Medicine and Surgery, University of Milano Bicocca, Milano, Italy, [3]Department of Pathology, University of Michigan School of Medicine, Ann Arbor, [4]Department of Human Genetics, University of Miami Miller School of Medicine, Miami, United States

Background: The dic(1;7)(q10;p10) is a centromeric-centromeric DNA juxtaposition, usually found in Myelodysplastic Syndromes (MDS) and Acute Myeloid Leukemia (AML) arising after chemo/radio-therapy. Due to the absence of genes within the epigenetically defined centromeric region, no specific molecular targets have been identified yet.
Aims: The aim of this study was to characterized biological features of MDS/AML with dic (1;7) by investigating their genetic and epigenetic landscape.
Methods: Three series of 5 cases each were selected for the study: 1) MDS/AML with dic(1;7); 2) t-MDS/AML; 3) non-neoplastic cytopenias. DNA and RNA were extracted from unsorted bone marrow cells. Genomic characterization of dic(1;7) included karyotype, Fluorescent *In situ* Hybridization (FISH), Single Nucleotide Polymorphism Array (SNPa), Whole Exome Sequencing (WES), and RNA sequencing. Global epigenetic approach used Enhanced Reduced Representation Bisulfite Sequencing (mERRBS). All amplified libraries were sequenced on Illumina HiSeq2500 using manufacturer's recommended protocol and were aligned against hg19.
Results: In all dic(1;7) cases breakpoints fell within α-sat DNA at chromosome 1 and 7, resulting in a 1q trisomy and 7q monosomy. SNPa excluded copy neutral loss of heterozygosity or cryptic copy number alterations, confirming dic(1;7) as a cytogenetically primary abnormality. WES did not identify a common mutational background in dic(1;7) series. Two patients harbored 4 somatic mutations never described in MDS/AML (*EB1*; *GGPS1*; *CCDC8*; *PSMF1*). Gene expression profile (FDR ≤0.1, $\log_2$FC ≥I1I) provided us with a specific downregulation signature differentiating dic(1;7) from both controls [4860 differentially expressed genes (DEGs): 889 up and 3971 down] and t-MDS/AML [4317 DEGs: 482 up and 3835 down]. To characterize the biological differences, we analyzed DEGs within functional pathways, which identified downregulation of ATP-binding cassette transporters and upregulation of p53 signaling only in dicentrics (FDR ≤0.05). We next investigated the gene dosage effect of 1q trisomy and 7q monosomy. In keeping with 7q monosomy, 95% of DEGs on 7q were downregulated in dic(1;7). Surprisingly, the gene dosage effect of 1q trisomy contributed only partially, with more than 50% of 1q DEGs being downregulated in dicentrics. In exploring the basis for the dic(1;7)-related 1q downregulation, the DNA methylation profile identified hypermethylation at 1q in dicentrics in keeping with downregulation signature despite trisomy. Global epigenome analysis, which capture around 3.2M of CpGs, was able to separate dic(1;7) and t-MDS cases from each other and from controls. Moreover, mERRBS showed a specific dic(1;7) hypermethylation pattern in non-promoter regions, particularly at intronic enhancers. We used PET Module tool to identify putative enhancer-target genes, which hypo-expression gave account of around 30% of the downregulated signature. Furthermore, Hypergeometric Optimization of Motif EnRichment analysis showed that hypermethylated enhancers were specifically enriched for the Krüppel-like factor protein family of transcription factors.
Summary/Conclusion: In conclusion our results first showed that the cytogenetically unbalanced dic(1;7) in MDS/AML is the hallmark of a specific

gene expression profile originated by epigenetic events, mostly enhancer hypermethylation. Biological features of dic(1;7), particularly its rare occurrence in complex karyotypes and the presence of p53 up-regulation, are separating MDS/AML with dic(1;7) from t-MDS/AML.

PB2077

CIRCULATING INFLAMMA-MIRNAS IN MYELODYSPLASTIC SYNDROMES

D. Mattiucci[1], E. Rossi[1], V. Mari[1], M. Mariani[1], T. Martini[1], V. Santini[2], E. Masala[2], S. Mancini[3], A. Olivieri[1], A. Poloni[1,*]

[1]Scienze Cliniche e Molecolari, Università Politecnica delle Marche, Ancona, [2]University of Florence, Firenze, [3]Università Politecnica delle Marche, Ancona, Italy

Background: Myelodysplastic Syndromes (MDS) are a heterogeneous group of clonal stem cell disorders affecting mainly the elderly and characterized by ineffective haemopoiesis, peripheral blood cytopenias and risk of developing acute myeloid leukemia. MicroRNAs (miRNAs) are small non coding single strand RNAs. miRNAs act inhibiting messenger RNAs (mRNAs) translation and decreasing their stability through a complementary base pairing and, on the basis of this regulatory role, abnormal miRNA levels are related to several pathological states. The presence of miRNAs in body fluids may represent a gold mine of noninvasive biomarkers in cancer. In particular, miRNAs in serum are linked with the presence of hematologic malignancies. In MDS, immune system dysregulation may represent a primary pathophysiologic abnormality and a key driver of the pathological evolution of MDS and it looks like chronic inflammation role is essential in MDS pathogenesis and progression: there is growing evidence implicating inflammation-related changes, inhibitory cytokines and increased intramedullary apoptosis as contributors to ineffective hematopoiesis.
Aims: In this study, we evaluated the expression of 15 miRNA which have been demonstrated to be dysregulated during ageing and in inflammatory conditions: miR-17; miR-9; miR-22; miR-152; miR-335; miR-19b; miR-20a; miR-34a; miR-146a; miR-181a; miR-9; miR-21; miR-126; miR-29a; miR-155.
Methods: Total RNA was isolated from the serum of 60 High Risk (HR) and Low Risk (LR) MDS patients and 30 donors and a quantitative analysis of the circulating miRNA was performed by Real Time PCR.
Results: Among 15 miRNA studied, the levels of miR-9, miR-17, miR-22, miR-34a, miR-152, and miR-335 were not detectable both in patients and donors. MiR-126, miR29a, miR20a, miR181a, 19b and miR21 show a statistically significant differential expression in both HR and LR patients with respect to controls. MiR-146a and miR-126 were altered only in LR-MDS (IPSS and R-IPSS) patients.
Summary/Conclusion: In this work it has been possible to evaluate inflamma-miRNAs' levels in MDS. In particular, these data could have a considerable significance in LR MDS, in which inflamma-miRNAs are aberrantly expressed respect to controls and could be the key regulators in the pathogenesis of ineffective erythropoiesis and anemia and also in myeloproliferation and oncogenic transformation.

PB2078

TREG LEVELS IN BONE MARROW OF LOW RISK MDS PATIENTS CORRELATE WITH PREFERENTIAL EXPANSION OF CYTOTOXIC T CELLS IN BONE MARROW AND A MORE FAVOURABLE PROGNOSIS

S. Leone[1,*], V. Rubino[2], A. Giovazzino[3], A.T. Palatucci[4], G. Cerciello[1], F. Pane[1], G. Ruggiero[3], F. Alfinito[1], G. Terrazzano[2]

[1]Dipartimento ad Attività Integrata di Ematologia, Oncologia, Anatomia Patologica e Diagnostica per Immagini, AOU Federico II, Naples, [2]Dipartimento di Scienze, Università della Basilicata, Potenza, [3]Dipartimento di Scienze Mediche Traslazionali, Università degli studi di Napoli Federico II, [4] Istituto per l'Endocrinologia e l'Oncologia Sperimentale, Consiglio Nazionale delle Ricerche (IEOS-CNR), Naples, Italy

Background: Several data have been showing that immune-dependent mechanisms might be relevant for the selection, expansion and dominance of dysplastic clone/s in a subgroup of Myelodysplastic (MDS) patients. To date, valuable criteria to identify patients in which a deranged immune response might account for the selection/shaping of the dysplastic precursor/s are still lacking. Immune response is a microsite phenomenon, thus the analysis of the immune effectors in the Bone Marrow (BM) offers a unique possibility to specifically focus the mechanisms underlying the immune-mediated processes likely involved in the selection/expansion of dysplastic clone/s in MDS.
Aims: We previously described that specific alterations of immune profile, as represented by low Treg levels and high expression of CD54 on CD8 effectors in BM, allow the identification of a subgroup of MDS patients in which an immune-mediated pathogenesis of the disease might be inferred. This study aims to confirm and extend these data trying to correlate tolerance control derangement in BM with pathological expansion of T cell effectors in Low Risk MDS patients. Moreover, we address the evaluation of Treg level as a valuable prognostic marker in Low Risk MDS.
Methods: To investigate the occurrence of antigen-dependent clonal expansion of CD4 and CD8 T lymphocytes, we analysed, by flow cytometry, TCR Vb repertoire in BM as compared with peripheral blood in 26 Low Risk patients and healthy donors. To evaluate the prognostic role of BM Treg at diagnosis, we have investigated the occurrence of leukemia evolution and overall survival in our cohort of patients in a minimal 36 month follow up.
Results: Preliminary data confirm that Treg, a key element for cell-mediated tolerance control, show a clustered distribution in BM; moreover, their quantitative defect correlates with the recruitment and the activation of T cell cytotoxic effectors in BM. The analysis of preferential CD4 and CD8 T cell expansion in BM, respect to peripheral blood, reveals the presence of oligoclonal BM expansions of CD8 and CD4 T lymphocytes. Notably, CD8 BM expansions are significantly related to low Treg level (<2% of BM lymphocytes). Moreover, our data indicate that the subgroup of patients with low BM Treg level, at diagnosis, shows significant lower leukemia evolution and death in a minimum 36 month follow up.
Summary/Conclusion: These data suggest that BM Treg level may represent a valuable criterion to identify the subgroup of Low Risk MDS patients in which immune-mediated mechanisms are relevant for MDS pathogenesis. A more homogeneous grouping of Low Risk patients will improve clinical management of the disease, hopefully allowing a more effective employment of innovative immune-modulating strategies in MDS.

PB2079

THE ANALYSIS OF EXPRESSION OF FOXP3 MOLECULE'S ISOFORMS BY REGULATORY CELLS IN PERIPHERAL BLOOD IN MYELODYSPLASTIC SYNDROME PATIENTS

G. Dudina[1,*], A. Mitin[2], M. Litvina[2], A. Donetskova[2]

[1]Hematology, Moscow Clinical Scientific Center (MCSC), [2]NRC Institute of Immunology, Moscow, Russian Federation

Background: Assuming that the immune system plays an active role in pathogenesis of myelodysplastic syndrome (MDS), it is expected that certain immune responses, namely, the number of regulatory T-cells (Treg cells), can be used as prognostic criteria. Participation of Tregs in pathogenesis of MDS can partly explain the link between MDS and autoimmune disorders, as well as tumor transformation.
Aims: Estimate the number of regulatory T-cells and level of expression of FOXP3 molecule isoforms differing by the exon-2 in peripheral blood of patients with MDS at early and late stages.
Methods: The evaluation was performed on peripheral blood mononuclear cells (PBMC). Various fluorochrome-labeled monoclonal antibodies (eBioscience) were used. As a negative control for establishing of gates for $FOXP3^+$ cells, we used a non-expressing FOXP3 molecules subpopulation of CD3-negative cells.
Results: 55 patients with MDS (WHO 2008) were examined. Patients with low and intermediate-1 risk of IPSS were included in the early-stage MDS group (E-MDS), and intermediate-2 and high-risk IPSS patients were included into the late stage MDS group (L-MDS). The obtained values for E-MDS and L-MDS groups did not differ significantly. When compared with the age control group, the absolute number of leukocytes, lymphocytes, and $CD4^+$ T-cells was found to be decreased, which is typical for MDS. In both groups, more than two-fold decrease in the absolute number of Tregs was registered. Treg decrease was proportional to the degree of leukopenia and somewhat more pronounced than decrease level of the number of lymphocytes and all $CD4^+$ T-cells, which is due to decrease of the proportion of Tregs among $CD4^+$ T-cells. The decrease of Treg percentage was statistically significant in the E-MDS group only, which suggests a higher probability of autoimmune disorders in this group. A significant decrease of the number of Tregs was shown, both expressing the complete FOXP3 molecule (FOXP3-FL Treg) and expressing only the FOXP3 molecule without exon-2 (FOXP3D2 Treg). Decrease of the number of FOXP3D Treg in peripheral blood was more pronounced than the decrease of FOXP3-FL Treg, which is due to a significant increase of the relative proportion of the latter. Presumably, the Treg functional activity in MDS is attenuated due to decrease of the proportion of FOXP3D2 Treg, known to be the most active suppressor of the immune response.
Summary/Conclusion: The data obtained shows a functionally intermediate role of Treg in MDS compared to inflammatory (autoimmune) diseases and

the norm, and its opposite role in malignant neoplasms. The basic mechanisms of MDS pathogenesis, including Treg function, need further study, which may lead to subdivision of different diseases with a distinctive clinical picture and outcome.

PB2080

VARIATION IN THE LEVEL OF AKT1 IN LYSATES OF BONE MARROW CELLS IN MYELODYSPLASTIC SYNDROMES

N. Klimkovich[1,*], O. Krasko[2], T. Kozarezova[1], M. Tishkevich[3]

[1]Department of pediatric oncology and hematology, Byelorussian Medical Academy of Post-Graduate Education, [2]Laboratory of Bioinformatics, United Institute of Informatics Problems of the National Academy of Sciences, [3]Institute of Bioorganic Chemistry of the National Academy of Sciences, Minsk, Belarus

Background: Oncoprotein kinase Akt (proteinkinase B) plays an important role in the regulation of the cell cycle, apoptosis, glucose metabolism and angiogenesis. There is an opinion that the quantitative level of the Akt kinase phosphoform can be considered as an independent prognostic marker for some types of human malignant neoplasms. Studies of the activated Akt protein are mainly produced in solid tumors. Such studies are few in hematology, but the prognostic and therapeutic prospects make them relevant.
Aims: Study of the level of Akt1 in lysates of bone marrow cells in patients with MDS and an estimation of its prognostic value.
Methods: The level of the activated form of the anti-apoptotic protein Akt1 was analyzed in74 patients with *de novo* myelodysplastic syndromes (MDS) and 11 with acute myeloid leukemia (AML) as a comparison group. Akt1 in the lysates of bone marrow cells was determined by the EIU the Total-Akt1 DuoSet IC kit (R&D Systems, Inc. USA). The measurements were carried out on an iMark microplate reader (BioRad, Japan). Statistical analysis was made with statistical tools R version 3.1.3.
Results: A high level of the activated form of Akt1 in the lysates of bone marrow cells was established for AML (1428 (103 ... 2319) pg/ml) and for MDS (528.25 (225.9 ... 1788.3) pg/ml) in relation to the control (165.95 (104.5 ... 236.1) pg / ml). In RA, 5q-syndrome and RCMD there was low content of Akt1 compared to RAEB variant: 286.95 (225.9 ... 1788.3) pg/ml for RA and 5q-syndrome, 526.7 (235.8 ... 1765.8) pg/ml with RCMD, 714.3 (235.8 ... 1775.3) pg/ml for RAEB. Analysis of the content of Akt1, depending on the cytogenetic status of bone marrow cells in patients with MDS, showed that the maximum concentration of Akt1 (726.8 (289.6 ... 1316.7) pg/ml) corresponds to multiple karyotype anomalies. The minimum concentration of Akt1 was registered in isolated del 5q31 (286.25 (225.9 ... 289.5) pg/ml). In groups with normal karyotype and isolated chromosomal abnormalities the content of Akt1 in the lysates of bone marrow cells did not differ. Expression of CD95 and FLT3 (CD135) by bone marrow cells has a nonlinear dependence on the level of Akt1. At the Akt1 level in bone marrow cell lysates over 500 pg/ml, the CD95 expression fast falls below 20% and FLT3 (CD135) expression increases by more than 40%. Death of patients with Akt1 content in bone marrow cell lysates more than 500 pg/ml was recorded in 82.5% of cases, and in patients with a concentration of Akt1 less than 500 pg/ml, 44.1% of cases ($p<0.001$). Transformation to acute leukemia was more frequent with an Akt1 content of more than 500 pg/ml (62.5%) compared to lower values of this parameter (41.2%), $p=0.067$. The timing of the onset of MDS transformation into leukemia is statistically significant: 71 (6 ... 340) weeks with Akt1 less than 500 pg/ml and 23.5 (3 ... 133) weeks with Akt1 greater than 500 pg/ml ($p<0.001$).
Summary/Conclusion: An increase in the concentration of the activated form of the Akt1 protein in bone marrow cell lysates corresponds to unfavorable variants of MDS that have a high risk in the IPSS system. The level of Akt1 in bone marrow cell lysates is more than 500 pg/ml and is the threshold for blocking apoptosis and the activity of clonal proliferation. The increased level of the activated form of Akt (more than 500 pg/ml) in the lysates of bone marrow cells can be considered as an independent prognostic marker of the progression of MDS.

PB2081

HIF-1A EXPRESSION IS ASSOCIATED WITH PRIMARY RESISTANCE TO AZACITIDINE IN MDS PATIENTS – DATA FROM THE HELLENIC MDS STUDY GROUP

V. Bakou[1], A. Spathis[2], F. Kontsioti[1], A. Bouhla[1], G. Stavroulaki[1], I. Glezou[1], K. Godopoulos[1], S. Papageorgiou[1], E. Bazani[1], D. Vasilatou[1], N. Viniou[3], A. Galanopoulos[3], K. Zafeiropoulou[4], I. Kotsianidis[5], A. Symeonidis[4], G. Dimitriadis[1], V. Pappa[1,*]

[1]Second Department of Internal Medicine and Research Institute, [2]Department of Cytopathology, Attikon University General Hospital, [3]The Hellenic MDS study group, Athens, [4]The Hellenic MDS study group, Patra, [5]The Hellenic MDS study group, Alexandroupoli, Greece

Background: Hif-1α expression has been previously associated with an adverse prognosis in patients with solid tumors and some hematological malignancies. Moreover, it was recently correlated with poor overall survival and disease progression in MDS. Hif-1α is also known to regulate the expression of human equilibrative nucleoside transporters (ENTs) and ribonucleotide reductase (RR), both of which are involved in the metabolism of hypomethylating agents, such as azacitidine. AZA is the standard of care for patients with high-risk myelodysplastic syndromes (MDS) and AML patients not candidate for treatment with intensive chemotherapy. Nevertheless, approximately 40% of patients fail to respond, whereas even responders will inevitably relapse.
Aims: This study aims at investigating the expression level and clinical significance of Hif-1α in both MDS AZA responders and non-responders, before and after treatment.
Methods: Bone marrow samples from 39 *de novo* MDS patients, 5 CMML patients and 12 AML [43 M/13 F, median age 75 (52-89)] and 10 healthy donors were collected. MDS patients were classified according to WHO as RCMD (4/39), RAEB I (11/39) and RAEB II (24/39) and according to IPSS as low (3/39), intermediate-1 (7/39), intermediate-2 (13/39) and high (16/39). All patients received AZA treatment at the dose of 75mg/m^2 x7 days SC. Low and inter-1 MDS patients received azacitidine as off label therapy. BM samples from 29 MDS [RCMD (1/29), RAEB I (9/29), RAEB II (19/29)], 2 CMML and 2 AML of the aforementioned patients were also collected 6 months after AZA therapy [26 M/7 F, median age 75 (52-89)]. After BM mononuclear cells' isolation (Ficoll-paque method), RNA extraction (TRIzol method) and cDNA preparation (Superscript II reverse transcriptase), Hif-1α expression was estimated by Rt-PCR TaqMan gene expression assay. Relative gene expression was calculated by comparative threshold cycle (ΔΔCt) method. β-actin was used as a housekeeping gene. Statistical analyses were performed through Kruskal Wallis, Mann-Whitney U and Wilcoxon signed rank tests.
Results: Out of the 56 patients used in our study, 32 responded to azacitidine-treatment (including CR, PR and HI) while 24 failed to respond. AZA responders presented with a statistically significantly increased $2^{-\Delta\Delta Ct}$ ratio of Hif-1α/β-Actin median expression compared to both control samples and non responders (1.377 *vs* 0.698 and 0.73, $p=0.004$ and 0.008, respectively). AZA non-responders presented no statistical significance compared to control samples. Hb levels were not significantly different between R and NR patients' groups. Moreover, an increase in Hif-1α expression was observed comparing Inter-I and Inter-II IPSS risk groups (0.730 *vs* 1.672, $p=0.037$) in all MDS patients examined, while a positive correlation between Hif-1α expression and IPSS-R risk scores (CC=0.371, $p=0.024$) was also found. Finally, the $2^{-\Delta\Delta Ct}$ ratio of Hif-1α/β-Actin median expression after 6-months of therapy presented a decreasing trend for both responders [from 1.377 to 1.269 (7.85% decrease)] and non-responders [from 0.730 to 0.598 (18% decrease)].
Summary/Conclusion: Our data indicate that patients with increased pretreatment Hif-1α expression seem to better respond to AZA therapy. Hif-1α expression gradually increases across IPSS and IPSS-R subgroups, suggesting an association of Hif-1α with a more aggressive disease. Moreover, AZA treatment seems to downregulate Hif-1α expression in both responders and non responders, indicating a potential role of hypoxia signaling in azacitidine resistance.

Orsola-Malpighi Hospital, Bologna, [7]Department of Hematology, San Giovanni-Addolorata Hospital, [8]Hematology Institute, Università Cattolica del Sacro Cuore, [9]Laboratory of Onco-Hematology, Santa Lucia Foundation, Rome, Italy

Background: Somatic mutations are one of the major factors driving the

pathogenesis of myelodysplastic syndromes (MDS) and are closely associated with clinical phenotype. The iron-chelator deferasirox (DFX) has been shown to induce hematologic response (HR) in about 10% of patients with MDS, with a yet unknown mechanism.

Aims: Our aim was to evaluate the role of somatic mutations in critical genes as predictors of hematologic response to DFX.

Methods: Sixty diagnostic bone marrow samples from 19 patients responsive and 41 resistant to DFX were tested in this study. Thirty genes known to be frequently mutated in haematological malignancies were screened for somatic mutations in 15 patients (7 responsive and 8 resistant) using NGS based on the commercial Myeloid Solution by SOPHiA GENETICS (SOPHiA GENETICS, Saint-Sulpice, Switzerland). The resulting captured libraries were further processed on a HiSeq® sequencing platform (Illumina, San Diego, California). Generated FASTQ sequencing files were then uploaded to SOPHiA DDM® platform (SOPHiA GENETICS, Saint-Sulpice, Switzerland). An additional cohort of 45 patients was screened for mutations in the hot-spot regions of spliceosome machinery enzymes (SF3B1, SRSF2, U2AF1) and epigenetic regulators (IDH1, IDH2 and DNMT3A), using Sanger sequencing.

Results: Using NGS, we identified 53 mutations with a variant allele frequency (VAF) ≥1%, with at least 1 mutation in 14 of 15 patients (93.3%). The median number of mutations per patient was 3.53 (range, 0-6). As reported in figure 1a, the most commonly mutated genes were: ASXL1 in 9 of 15 pts (60%) and RUNX1, DNMT3A, SF3B1 and TET2 in 4 of 15 pts (27%). In this analysis, none of the single gene was predictive of HR to Deferasirox treatment, while mutation frequency in general was lower in responders, as compared to resistant patients (mean 2.4 *vs* mean 4.5 mutations/patient, respectively; p=0.0232). When extending the mutational screening to further 45 patients by Sanger sequencing, we identified SF3B1 as the most commonly mutated gene. Although the cumulative frequency of SF3B1 mutations in the entire cohort of patients (23/60 pts, 38.3%) appeared to be higher in resistant as compared to responsive patients (17/41, 41.5%, *vs* 6/19, 31.6%), the difference did not reach statistical significance.

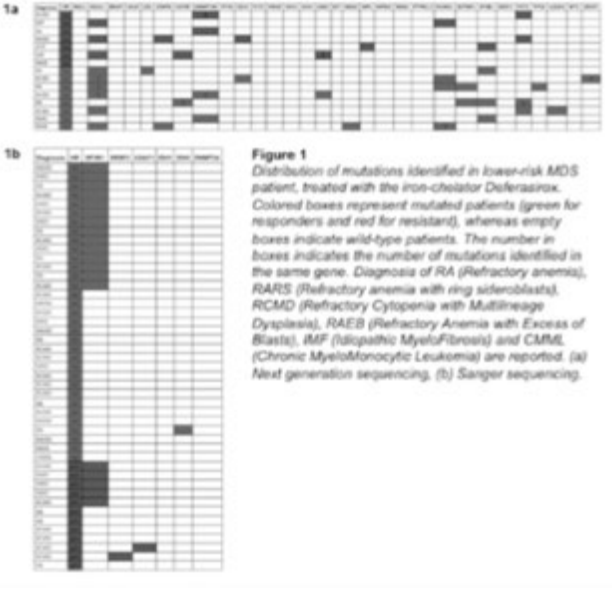

Figure 1
Distribution of mutations identified in lower-risk MDS patient, treated with the iron-chelator Deferasirox. Colored boxes represent mutated patients (green for responders and red for resistant), whereas empty boxes indicate wild-type patients. The number in boxes indicates the number of mutations identified in the same gene. Diagnosis of RA (Refractory anemia), RARS (Refractory anemia with ring sideroblasts), RCMD (Refractory Cytopenia with Multilineage Dysplasia), RAEB (Refractory Anemia with Excess of Blasts), IMF (Idiopathic MyeloFibrosis) and CMML (Chronic MyeloMonocytic Leukemia) are reported. (a) Next generation sequencing, (b) Sanger sequencing.

Figure 1.

Summary/Conclusion: Our preliminary data show that mutational screening performed by NGS of lower-risk MDS may have a role in predicting hematologic response to Deferasirox treatment, whereas the sole presence of SF3B1 mutations is not associated to hematologic response.

Background: The importance of the identification of somatic mutations in myeloid neoplasms has increased dramatically in the last ten years. The study of these mutations has improved the understanding of bone marrow (BM) clonal expansion that occurs in these malignancies. Mutations in genes participating in the mechanism of splicing and epigenetics are found in patients with clonal cytopenia of undetermined significance (CCUS), myelodysplastic syndrome (MDS), myelodysplastic/myeloproliferative neoplasm (MDS/MPN) and acute myeloid leukemia with myelodysplasia-related changes (AML-MRC). The evaluation of somatic mutations profiles in the Brazilian population has clinical relevance due to the great ethnic differences found in our population as compared to the North American and European populations, where the vast majority of these studies were conducted.

Aims: Evaluation of the frequency of somatic mutations in genes: *SF3B1, TET2, U2AF1, IDH1/2, tp53* in patients from the city of Salvador, Bahia, Brazil, with diagnoses of CCUS, MDS, MDS/MPN and AML-MRC.

Methods: In this observational study, 50 untreated patients ≥18 years were analyzed. Blood counts, cytogenetic and BM analysis were performed. DNA was isolated from BM and PCR analyzes was performed. All patients provided informed consent.

Results: From the 50 patients analyzed, 24 were diagnosed with cytopenias (48%), 18 with MDS (36%), 5 with MDS/MPN (10%) and 3 with AML (6%). Overall, 29 patients were female (58%) and 21 were male (42%). The mean age was 60.5 years (range 22-84). Mutated genes were found in 19 patients (38%). Ten patients showed mutations in *U2AF1* gene (20%), 6 (12%) in *TET2*, one (2%) in *SF3B1*, one (2%) in *IDH2* and one (2%) in *TP53* mutated. The coexisting mutations were found in four patients, as follows: *IDH2* + *SF3B1*, *SF3B1* + *TET2*, *U2AF1* + *IDH2* and *U2AF1* + *TET2*. Eleven patients (45,8%) presented mutations in the cytopenias group. From these, 7 cases showed mutations in *U2AF1* and the remaining four cases had mutations in *SF3B1*, *TET2*, *IDH2* and *TP53*. All the coexisting mutations found were in this group. In the MDS group, *TET2* mutations were found in four (38,9%) patients and *U2AF1* mutations were found in 16,7% (n=3). No mutations were observed in the AML group and one patient (20%) presented mutation in *TET2* gene in the group MDS/MPN (p=0,66). From the 27 patients <60 years of age, 9 (40,9%) showed mutations: four had *U2AF1* mutated, two patients presented mutation in *TET2* and three presented mutations in *SF3B1*, *IDH2* and *TP53*. From the 27 patients >60 years of age, 10 (37%) presented mutations: 6 in *U2AF1* and four in *TET2* (p=0,66). All of the patients with coexisting mutations were <60y. Mutations were not differentially associated with sex. Of 21 male patients, 9 (42,9%) had one or more mutations. Of the 29 female patients, 10 (34,5%) had mutations (p=0,55). The majority of patients analyzed had <2% blasts in the BM, hemoglobin levels ≥10g/dL, neutrophils ≥800/μL and platelets ≥100,000/μL (Figure 1).

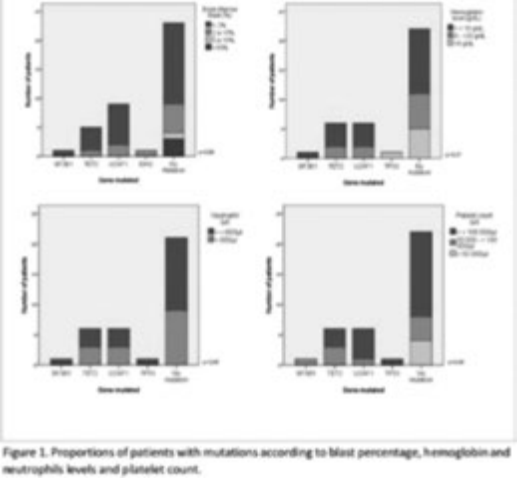

Figure 1.

Summary/Conclusion: Differently from literature data, the main gene mutated was *U2AF1*, found in 20% of cases here, as opposed to ~ 8%

found in other studies. The cytopenias group presented the highest number of cases with mutations. Moreover, the number of coexisting mutations was higher in this group and the same were found only in patients <60y. This is a preliminary study, that is under development to increase the number of enrolled individuals and might be added to other Brazilian studies, aiming to define the mutation profile of myeloid neoplasms in Brazil.

THE HYPERMETHYLATION PROFILE OF APOPTOTIC GENES IN MYELODYSPLASTIC SYNDROMES

F. Zaker[1,*], N. Nasiri[1], N. Amirizadeh[2], M. Razavi[3]

[1]Lab haematology, Iran University Of Medical Sciences, [2]Higher education institution, iranian blood transfusion service, [3]Department hematology oncology, Iran University Of Medical Sciences, tehran, Iran, Islamic Republic Of

Background: MDS is a clonal disorder which patients have pancytopenia, anemia and transfusion dependent. This disorder progress to AML in 1:3 of cases and resistant to chemotherapy. Several molecular mechanisms involved in pathogenesis of MDS including hypermethylation of selected genes in different manner like apoptosis, cell cycle, and tumor suppressor.
Aims: In this work we studied methylation and epigenetic of several genes including FOXO3, CHK2, HRK and PTEN involved in apoptosis and relationship to biological characteristic and karyotype and subgroup of MDS and IPSS.
Methods: We studied 54 patients enrolled in Shariati Hospital, Firozgar hospital and other therapuetic center in Tehran. PB or BM were collected and DNA and RNA extracted. DNA was bisulfitted, methylated and measured by MS-HRM. cDNA synthesized from RNA and expression of genes studied by REAL TIME PCR. SPSS 16 software was used to analyse the data.
Results: The most frequency of methylation occurred in CHK2 gene which has been seen in all subtypes of MDS including RAEB1, 2. The advanced stage of MDS showed the most hypermethylation status compare to early PCR stage. The most hypermethylation of gene occurred in high and very high subgroup of IPSS-R. Real time showed downregulation of selected genes which were in parallel to hypermethylation pattern.
Summary/Conclusion: The data showed hypermethylation of all selected genes inviolve in apoptosis could explain the mechanisms and pathogenesis in MDS in partly. This hypermethylation was parallel to decease in expression of selected genes.

THE ROLE OF FLT3-ITD MUTATION ON DE NOVO MDS AMONG CHINESE POPULATION

F. Xu[1,2], R. Han[2], J. Deng[3], Q. Qiu[2], H. Shen[2], S. Chen[2], D. Wu[2], S. Xue[2,*]

[1]Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, [2]The First Affiliated Hospital of Soochow University,Jiangsu Institute of Hematology, [3]Suzhou Center for Disease Control and Prevention, Suzhou, China

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of myeloid neoplasms characterized by aberrant myeloid differentiation, ineffective hematopoiesis and potency of secondary acute myeloid leukemia (sAML) progression. The underlying mechanism of this transformation has long been the hit topic among hematologists. Besides, with the nature of heterogeneity seen in MDS, scoring systems were introduced to evaluate the prognosis of patients with MDS, such as IPSS-R, yet leaving molecular patterns out of them. Meanwhile, the role of FLT3 gene in AML has been well documented and put into practice. Nevertheless, with a rather low incidence of mutation in MDS group (0.6%>6%), the role of FLT3 mutation has not been revealed fully in real world MDS.
Aims: The present study was performed to investigate: the mutation patterns of FLT3 in MDS among Chinese patients; the impact of FLT3 on prognosis of Chinese MDS patients; and the association between FLT3 mutations and secondary AML transformation.
