ABSTRACT

SNAP-25 is a SNARE protein implicated in exocytosis and in the negative modulation of voltage gated calcium channels. We have previously shown that GABAergic synapses, which express SNAP-25 at much lower levels relative to glutamatergic ones, are characterized by a higher calcium responsiveness to depolarization and are largely resistant to botulinum toxin A. We show here that silencing of SNAP-25 in glutamatergic neurons, a procedure which increases KCl-induced calcium elevations, confers these synapses with toxin resistance. Since it is known that calcium reverts the efficacy of botulinum A, we investigated whether the lower effectiveness of the toxin in inhibiting GABAergic vesicle cycling might be attributable to higher evoked calcium transients of inhibitory neurons. We demonstrate that either expression of SNAP-25_{1-197} or BAPTA/AM treatment, both inhibiting calcium dynamics, facilitate block of GABAergic vesicle exocytosis upon toxin treatment. These data indicate that intrinsic calcium dynamics control botulinum A susceptibility in distinct neuronal populations.

1. INTRODUCTION

SNAP-25 belongs to the SNARE superfamily of membrane proteins that participate in synaptic vesicle (SV) exocytosis. It contributes two alpha-helices in the formation of the exocytotic fusion complex together with syntaxin-1 and synaptobrevin/VAMP [1, 2]. Besides acting as a fundamental component of the SNARE complex, SNAP-25 has been shown to negatively modulate voltage gated calcium channels in various overexpression systems [3, 4] and in cultured hippocampal neurons [5, 6].

Botulinum neurotoxin A (BoNT/A) is a protease specific for SNAP-25. Although the BoNT/A-generated fragment, SNAP-25_{1-197}, retains the capability to form the exocytotic fusion complex [7, 8], SNAP-25 proteolysis by the toxin reduces the probability of vesicle fusion and inhibits neurotransmitter release. It has been previously shown that BoNT/A preferentially inhibits SV recycling at glutamatergic terminals and is more efficient in impairing the release of excitatory than inhibitory neurotransmitters [5, 9, 10, 11]. Lower susceptibility of GABAergic terminals to BoNT/A does not result from a defective toxin penetration, in line with the presence of the BoNT/A receptor SV2 in inhibitory neurons [11]. Notably the different susceptibility to BoNT/A of glutamatergic and GABAergic cells correlates with the levels of expression of the toxin substrate SNAP-25 in the two neuron types. Indeed, although most cultured GABAergic neurons use SNAP-25 for evoked exocytosis [12, 13, 14], they are characterized by lower levels of SNAP-25 as compared to glutamatergic terminals [5, 15, 16, 17] and become sensitive to BoNT/A upon exogenous expression of the protein [11]. Why BoNT/A is highly efficient in inhibiting vesicle cycling selectively in neurons expressing high levels of SNAP-25 is still to be defined. The clarification of
this point may have important implications, especially in consideration of the wide use of BoNT/A for the treatment of human diseases, and in view of its employment in CNS pathologies [18, 19, 20].

2. MATERIALS AND METHODS

2.1 Hippocampal neuronal cultures

Primary cultures of rat hippocampal neurons were prepared from the hippocampi of 18 day-old fetuses as previously described [11]. Neurons were transfected using the calcium phosphate precipitation method. Silencing of SNAP-25 was achieved via transfection of a pSUPER construct provided by T. Galli (Paris, France) [5]. The cDNA for SNAP-25\textsubscript{1-197} and SNAP-25\textsubscript{1-180} were generously provided O. Rossetto (Padua, Italy).

2.2 Exo-endocytotic assay

BoNT/A was a kind gift of Prof. Eric Johnson, Madison Wisconsin, purified and stored as previously described [11]. Control or transfected cultures were exposed to 125 nM BoNT/A for 2 hours at 37°C, before being assayed for SV recycling with monoclonal antibodies directed against the intravesicular domain of synaptotagmin I (Syt-ecto Abs; clone 604.2, kind gift of Dr. R. Jahn, Gottingen) as previously described [11]. Cultures were counterstained with polyclonal antibodies directed against vGLUT-1 (1:300, Synaptic Systems), vGAT (1:400–800; Synaptic Systems) or GAD (human sera recognizing GAD, kind gift of Dr. Solimena, Dresden). In a set of experiments recycling of GABAergic vesicles was evaluated using anti vGAT luminal antibodies (vGAT ecto, kind gift of Dr. H. Martens, Synaptic Systems). Cultures were co-stained with monoclonal anti-VGAT-N (Synaptic Systems). Images were acquired using Zeiss LSM 510 Meta confocal microscope and analyzed by Image J software. vGLUT positive recycling synapses, transfected with siRNA construct, were revealed by generating a binary mask of siRNA/vGLUT double-positive images. Total fluorescence (area per mean grey value) of Syt-ecto positive synapses expressing the siRNA construct, identified by the binary mask, were normalized to the total fluorescence of the corresponding v-GLUT staining. Syt-ecto/vGLUT fluorescence ratios of siRNA-transfected synapses were compared to those of non transfected vGLUT synapses. vGAT positive recycling synapses, transfected with SNAP-25-HA fragments, were revealed by generating a binary mask of SNAP-25-HA/vGAT double-positive images. The number of Syt-ecto positive synapses expressing SNAP-25-HA, identified by the binary mask, was calculated. Synapses were scored as positive for Syt-ecto Ab internalization when the fluorescence intensity was at least 2.5 to 3
times higher compared with cultures exposed only to secondary antibodies. For BAPTA experiments, vGAT positive synapses were revealed by generating a binary mask of vGAT images. Total fluorescence (area per mean grey value) of GABAergic Syt-ecto synapses, identified by the binary mask, were normalized to the total fluorescence of v-GAT staining. At least 10 fields containing excitatory/inhibitory synapses were analyzed, in three independent experiments. Quantitative analysis of SNAP-25 downregulation and overexpression in hippocampal cultures transfected with SNAP-25/GFP or cotransfected with iSNAP25 – GFP was carried out with monoclonal antibodies directed against SNAP-25 (SMI81, Sternberger Monoclonals, Baltimore MD). Images were acquired using Zeiss LSM 510 Meta confocal microscope and analyzed by Image J-1.4.3.67 NIH software. SNAP-25 expression was measured as mean grey value in neuronal processes of transfected and non-transfected cells.

2.4 Calcium measurements

Cultures were loaded with the ratiometric calcium dye FURA-2/AM as previously described [5]. Polychrome IV (TILL Photonics, Grafelfing, Germany) was used as a light source. Fura-2 fluorescence images were collected with a PCO Super VGA SensiCam (Axon Instruments, Forest City, CA, USA) and analysed with TILLvision software. After excitation at 340 and 380 nm wavelengths, the emitted light was acquired at 505 nm at 1–4 Hz. The ratio values in discrete areas of interest were calculated from sequences of images to obtain temporal analyses. Calcium concentrations were expressed as F340/380 fluorescence ratios.

2.5 Statistical analysis

Results are presented as means ± S.E. Data were statistically compared using the Student’s t test by using Origin software (Origin Lab, Northampton). One asterisk means p< 0.05, two asterisks p<0.01.

3. RESULTS

3.1 Levels of SNAP-25 expression influence neuron sensitivity to BoNT/A

We have previously shown that GABAergic SV exocytosis, monitored by antibodies to the intravesicular domain of synaptotagmin I (Syt-ecto), is highly resistant to BoNT/A [5, 11]. By monitoring GABAergic vesicle fusion with antibodies recognizing the C-terminus of the vesicular GABA transporter vGAT (vGAT ecto) [21], we confirmed that the majority of GABAergic terminals, intoxicated with 125 nM BoNT/A, internalized vGAT ecto
antibodies upon exposure to 55 mM KCl for 4 min; exocytosis was instead efficiently blocked by tetanus toxin (20 nM, TeNT) which cleaves synaptobrevin/VAMP-2 (figure 1A). Conversely, BoNT/A treatment inhibited SV recycling at excitatory synapses, monitored by antibodies to the intravesicular domain of synaptotagmin I (Syt-ecto) (figure 1B). SNAP-25 overexpression in GABAergic terminals was reported to largely increase sensitivity to BoNT/A and prevent Syt-ecto internalization [11]. To complement this finding and confirm that the expression level of SNAP-25 is an important determinant in neuronal sensitivity to BoNT/A, we investigated the effect of reducing SNAP-25 expression in glutamatergic neurons by co-transfection of cDNA codifying nucleotides 321 to 339 of rat SNAP-25 together with GFP (siRNA sequence). SNAP-25 expression was reduced of about 60% at 1-2 days after transfection (figure 1C, quantitation) and progressively decreased to levels not reliably quantifiable (figure 1C, arrow). Downregulation of SNAP-25 did not impair Syt-ecto Abs internalization at excitatory terminals (figure 1D), thus implying that low levels of the protein are sufficient to mediate SV fusion, as already demonstrated in cultures derived from SNAP-25 heterozygous mice [13, F. Antonucci, I. Corradini, C. Verderio and M. Matteoli, unpublished observations]. Cultures co-transfected with SNAP-25 siRNA sequence and GFP were exposed to BoNT/A and SV recycling was assayed using Syt-ecto Abs. A larger resistance to BoNT/A was detected at SNAP-25-silenced excitatory synapses. Indeed, the percentage of excitatory synapses resistant to intoxication raised from about 20% in controls to 40% after siRNA treatment (figure 1E). Furthermore the extent of recycling in SNAP-25-silenced boutons was higher as compared to the BoNT/A resistant terminals, either non transfected or GFP transfected (figure 1E and F). Overall these data support the concept that variations in the expression of the SNARE at nerve terminals underlie differences in BoNT/A sensitivity.

3.2 Reduction of neuronal calcium transients enhances sensitivity of GABAergic terminals to BoNT/A

BoNT/A cleaves SNAP-25 at residue 197 to generate a membrane bound NH₂-terminal SNAP-25 1-197 fragment, while BoNT/E removes a larger C terminus region of the protein by cleaving SNAP-25 at residue 180. The 17 amino acids between the cleavage sites for BoNT/A and BoNT/E are known to be required for high affinity binding of SNAP-25 to syntaxin 1 [22], for ternary complex formation with VAMP-2 and syntaxin 1 [7], for Ca²⁺-triggered membrane fusion [23] and Ca²⁺-dependent synaptotagmin binding [24]. In addition, the C-terminal region of SNAP-25 between BoNT/A and BoNT/E cleavage sites is also required for SNAP-25 modulation of voltage gated calcium currents [5, 6].

To get insights into the mechanisms by which overexpression of SNAP-25 confers GABAergic neurons with BoNT/A sensitivity [11], hippocampal cultures were transfected with plasmids encoding portions of SNAP-25
SNAP-25\textsubscript{1-180} and SNAP-25\textsubscript{1-197} fused to a HA-tag. SV fusion was monitored in transfected GABAergic terminals upon BoNT/A intoxication. While no significant reduction of SV exocytosis was detected at intoxicated GAD positive synapses expressing the SNAP-25\textsubscript{1-180} fragment, SV fusion was strongly impaired at GAD positive synapses expressing SNAP-25\textsubscript{1-197} (figure 2A-C). SV recycling was only analyzed at terminals where the expression levels of the transfected fragment was increased of about 2 folds, excluding those terminals expressing higher protein amounts (3-8 folds, figure 2C). This effect was not due to an inhibitory action of SNAP-25\textsubscript{1-197} fragment on SV fusion, since exogenous expression of the fragment in inhibitory neurons did not impair vesicle recycling (figure 2D). These results indicate that SNAP-25\textsubscript{1-197}, but not SNAP-25\textsubscript{1-180} is able to enhance GABAergic neuron sensitivity to BoNT/A, similarly to full length SNAP-25 [11].

It has been previously shown that BoNT/A-inhibition of SV fusion can be overcome by high calcium concentrations [25, 26, 27]. Based on this finding, Delgado-Martinez et al. [12] suggested that the lower efficacy of BoNT/A in inhibiting GABAergic vesicle cycling might be attributable to the higher calcium responsiveness of GABAergic relative to glutamatergic neurons. Given SNAP-25\textsubscript{1-197} but not SNAP-25\textsubscript{1-180} negatively modulates evoked calcium responses [5], the possibility opens that SNAP-25\textsubscript{1-197}, as the full length protein, enhances BoNT/A sensitivity by reducing calcium currents. To directly address this hypothesis, cultures were treated with the membrane permeable calcium chelator BAPTA/AM (25 μM) for 15 or 20 min. BAPTA/AM incubation for 15 min reduced by about 30% peak calcium transients evoked by 55 mM KCl (figure 3A, B) and only mildly affected depolarization-induced SV fusion at GABAergic synapses (fig. 3C-D). Of note, BAPTA/AM largely increased the sensitivity of GABAergic terminals to BoNT/A (figure 3 E and F). Although monitoring of Ca\textsuperscript{2+} elevation was carried out in neuronal cell bodies, these data suggest that the higher [Ca\textsuperscript{2+}] responses at GABAergic terminals can overcome the blocking action of the toxin.

4. DISCUSSION

Given that BoNTs do not cross the blood–brain barrier, their action is normally limited to peripheral nerve terminals. However, when injected directly into the brain, BoNTs can intoxicate neurons of the central nervous tissue, which express both substrates and receptors of BoNTs, with specific patterns of distribution. The preferential expression of receptors/substrates at specific neurons might underlie the preferential efficiency of BoNTs at selected terminals [20]. In the case of BoNT/A, however, the different sensitivity of glutamatergic and GABAergic neurons to the toxin does not result from receptor expression [11]. It does not result either from the presence in GABAergic neurons of a BoNT/A-resistant substrate, such as SNAP-47 or SNAP-29, since SNAP-25 has been shown to
mediate GABA release in primary cultures [12, 13, 14]. Here we show that two treatments which reduce evoked calcium transients, ie transfection of SNAP-25_1-197 and exposure to BAPTA-AM, increase susceptibility of GABAergic neurons to BoNT/A. Conversely, downregulation of SNAP-25, which increases evoked calcium transients [5], makes glutamatergic neurons more resistant to BoNT/A. These data suggest that susceptibility of neurons to BoNT/A results from the intrinsic calcium responsiveness to depolarization, which, among different factors, is modulated by the level of expression of SNAP-25 [5, 6, 28]. Interestingly, different intracellular calcium dynamics do not affect toxin penetration [11]. Our data are consistent with previous evidences obtained in hippocampal slice cultures, where significant increases in mEPSC frequency were produced in BoNT/A-treated cultures by application of the Ca^{2+} ionophore ionomycin in the presence of 10 mM [Ca^{2+}] [25]. Similarly, elevating calcium concentration at the calyx of Held with the use of caged calcium, produced a strong reduction in the calcium sensitivity for release after the cleavage of SNAP-25 by BoNT/A [27]. Interestingly, besides the amplitude of the peak calcium transients, also the temporal pattern of depolarization-induced calcium elevations influences neuronal BoNT/A susceptibility. Indeed, BoNT/A has been reported to abolish CGRP release induced by high KCl or bradykinin in trigeminal ganglionic neurons, but not that induced by capsaicin, which evokes a more prolonged calcium response as compared to the other stimuli [8]. Under this respect, it is of note that GABAergic neurons display not only higher but also slowly inactivating calcium currents compared to glutamatergic neurons (S. Condliffe, I. Corradini, D. Pozzi, C. Verderio and M. Matteoli, unpublished results). Altogether these data indicate that, in addition to receptor and/or substrate expression, a different susceptibility to BoNT/A may also result from intrinsic calcium dynamics in distinct neuronal populations. These data add a relevant information for the use of BoNT/A in the therapy of neurological disorders caused by the unbalanced activity of excitatory neuronal populations where maintenance of GABAergic transmission could be advantageous. Among these disorders are epilepsy [19] and neuropathic pain [29].
