Intimate partner violence, which may involve sexual violence, is a widespread social problem that raises important medical, psychological, ethical, and legal concerns. As eloquently highlighted by Professor Khan in his editorial (Khan K. BJOG 2016:1249), intimate partner violence against adult women is much more than a health-related problem, since it destroys feelings of love, self-esteem, self-efficacy, and dignity, and is a clear example of gender inequality, as the very large majority of victims are women.

In this short communication we draw attention to sexual violence against adolescent girls, a particular kind of gender violence with destructive consequences on multiple levels. The World Health Organization has reported that for one-third of young girls throughout the world the first sexual experience was forced (http://www.who.int/ August 2016). Moreover, sexual violence is often underreported by the victims – due to feelings of shame, guilt or fear – thus these violent events could be even more frequent than described. The estimated proportion of sexually abused girls is alarming for different reasons. First, it suggests that sexual violence may be considered as a ‘normal’ experience during adolescence. Second, trauma exposure in adolescence can negatively affect psychological wellbeing, with increased risk of social adjustment difficulties and impaired family functioning. Moreover, a history of maltreatment during adolescence has also been associated with the development of borderline or schizoid personality disorders (Krupnik JL et al. Psychiatry 2004;67:264-279).

In our centre for sexual and domestic violence (SVSeD- Milan, Italy), since 1996 we have adopted a holistic approach in our clinical practice with victims of violence, which entails considering health as associated with multiple factors, such as social, psychological and legal aspects. In working with adolescents who experienced partner or sexual violence, we have to be fully aware that the physical outcomes are only a part of their life history, though important. For these reasons we believe that the best approach is provided by a multidisciplinary team composed of different professionals figures (gynaecologists, paediatric surgeons, psychologists, social workers, forensic medical doctors, sexologists, lawyers, and other professionals required for special cases). Based on our
experience in the majority of cases violence against adolescents (aged 10-19) is perpetrated by a
relative or a friend, a neighbour or a teacher, in general by someone well known to the victim. Thus,
repeated sexual abuse may be frequent and particularly alarming. The negative consequences of
cumulative trauma exposure in the young developmental age are largely acknowledged as
particularly dangerous for physical and psychological growth.

Prevention and timely diagnosis are fundamental to reduce the risk of sexual violence. In this
regard, we believe in the importance of implementing prevention programmes targeted on the
specific developmental period and aimed at promoting sexual health education since the beginning
of the school cycle. Community-based programmes should entail the active participation of young
people. Moreover, training courses facilitating the prompt recognition of gender violence should be
including gynaecologists, paediatricians, and teachers. All these strategies may help prevent
violence, but still need further definition and implementation in many countries.
