severity of disease caused by these strains may be no less than that caused by recognized “enterohaemorrhagic” STEC serogroups such as O157 and O111. More widespread use of PCR- or enzyme-linked immunosorbent assay-based screening tests for the presence of STEC of any serogroup in animal samples will undoubtedly result in increased detection of similar non-O157 outbreaks in the future. This will provide more accurate data on the epidemiology of human STEC disease.

Meat products and meat preparations are very sensitive to external factors such as temperature and are good substrates for microbial growth and biochemical processes that occur during storage. The aim of this work was to study the effect of a selected lactic acid bacteria formulation (LAB) on the microbiological characteristics and colour of beef hamburgers stored at different temperatures. Two batches of hamburgers (average weight of about 100g) were prepared: one with the addition of LAB (Lactococcus lactis ssp. lactis, strain 340; L. lactis ssp. lactis, strain 16; Lactobacillus casei ssp. casei, strain 208 and Enterococcus faecium strain 614 in a ratio lactococci:lactobacilli:enterococci of 2:1:1) and one without (NO LAB), in three replicates done in three different days. For each batch, a subset of samples was stored under proper conditions (4°C) and the other at 40°C (temperature abuse conditions, to mimic inadequate storage conditions after purchase by consumer) both for 5 hours. After 5 hours, each subset was further divided into two subgroups: one maintained at 4°C and the other at 10°C. All hamburgers were evaluated on day-0, day-1, day-3, and day-5 for the following microbiological parameters (Staphylococcus spp., enterococci, Lactococcus spp., Lactobacillus spp., total mesophilic aerobes, Pseudomonas spp., total coliforms) according to standard methods; moreover colorimetric measurements were performed with Colorimeter - Digital Color Picker for iOS 10, under a 6500K light, with the CIELAB system, by taking three readings for each sample. The arithmetic means within each sampling was computed, subsequently all data (geometric mean for microbiological data) were elaborated with GraphPad InStat, 3.0b and GraphPad Prism 6.0d for Mac OS X. Two way analysis of variance (ANOVA) followed by the Tukey’s multiple comparisons test was performed. On day-5, all batches with LAB kept at abuse temperature and stored at 4°C had a higher blue-yellow, green-red and lightness coordinates compared to the batches made without LAB maintained at the same conditions. On day-5 Pseudomonas spp. (PS103) counts were significant lower ($p<.05$) in all batches made with LAB; Staphylococcus spp. (BP) counts were significant lower ($p<.05$) in batches made with LAB in abuse conditions.

In conclusion, the application of the proposed LAB formulation maintains hamburgers quality standards and can be a potential tool to increase their shelf-life.

Valorisation of former foodstuffs products (FFP) as feed ingredients is part of a long-term strategy for sustainability. Processing methods to convert FFP in to feed ingredients do not usually include packaging materials pre-removal. Feed processors routinely remove the packaging from surplus food mechanically. Although, the treatment in the plant removes most of the packaging, small amounts of wrapping materials can remain in the resulting feed. In this respect, the aim of this study was to investigate the safety features of selected FFP intended for animal nutrition produced from different confectionery products. In six FFP samples, both mash and pelleted, the presence of undesired ingredients which can be identified as remnants of packaging materials has been evaluated by two different methods. The first analysis has been done by stereomicroscopy, according to published methods, based on separation of every particle that is not native to the matrix by bare eye examination. In the second one, stereomicroscopy coupled with a computer vision system (IRIS Visual Analyzer VA400), has been tested in order to evaluate the presence/absence of packaging remnants in feed materials. Results obtained have been presented as percentage of
Camelina cake in laying hens diet to enrich eggs with omega-3 fatty acids

The aim of the trial was to evaluate the inclusion of 7.5% of camelina cake in the diet of laying hens on performance, egg quality characteristics, fatty acids composition and lipid oxidative stability. Thirty-two 26-weeks old Hy-Line Brown laying hens coming from the same flock were divided in two homogeneous groups and allocated in enriched cages (8 replicates per treatment) at the Experimental Station (Centro Zootecnico Didattico Sperimentale) of the University of Milan in Lodi. After an adaptation week, the trial lasted 8 weeks. Diets were formulated to meet requirements suggested for the genetic line and were isoproteic and isoenergetic. Performance were recorded weekly and two eggs per replicate were sampled on day 0, 28 and 56 of the trial. On the same samples, two yolks per replicate were pooled for fatty acid composition. Samples of two eggs per replicate were also collected at the end of the trial to evaluate egg quality characteristics and oxidative stability during egg shelf life (day 9, 21 and 28 from laying); for this aim, pooled yolk were analyzed for TBARS content. Data were analyzed by MIXED procedure by SAS. No differences were observed for hens’ body weights and eggs production during the trial, whereas feed intake and feed efficiency, expressed as feed intake over egg weight yield, were lower at week 6 and overall the experiment, respectively. No differences were detected for egg quality characteristics between treatments. Dietary camellina reduced by 3.5% saturated fatty acids and increased by 49% α-linolenic acid in egg yolk. No differences between treatments were evidenced for quality of eggs and TBARS yolk content during eggs shelf life. Inclusion of 7.5% of camellina cake in laying hens’ diets could reduce production costs and increase nutritional properties of eggs.

Olive oil extraction generates high amounts of by-products considered as potential pollutants. By-products are treated as industrial wastes or combustible material, heavy-metal absorbers and biofuel feedstock. One important alternative, considering the relatively high content in polyphenols, is the use of by-products from the olive oil industry as sources of nutrients for animals.

An olive mill wastewater polyphenols extract (OPE), obtained from aqueous waste through the use of a filtration system with progressive permeability membranes, was used as a supplement in a grower diet fed to broilers from 22 to 49 days of age. This was done in order to enrich eggs with omega-3 fatty acids. No differences were observed for hens’ body weights and eggs production during the trial, whereas feed intake and feed efficiency, expressed as feed intake over egg weight yield, were lower at week 6 and overall the experiment, respectively. No differences were detected for egg quality characteristics between treatments. Dietary olive mill wastewater reduced by 3.5% saturated fatty acids and increased by 49% α-linolenic acid in egg yolk. No differences between treatments were evidenced for quality of eggs and TBARS yolk content during eggs shelf life. Inclusion of 7.5% of olive mill wastewater in laying hens’ diets could reduce production costs and increase nutritional properties of eggs.
