A 3-year-old boy presented with 10 bluish to translucent, dome-shaped papules 1 to 3 mm in diameter on the tip of his nose (Figure 1). His parents had first noticed them when he was 8 months old and had observed an increase in number over time. They did not report any pruritus, and there was no association of the appearance of the papules with physical exercise, heat, or exposure to humidity. The boy was otherwise healthy, and the family history was unremarkable. One of the papules was excised by punch biopsy and histopathologic examination (Figure 3). Some of the lesions were covered by discrete scales. No hair, nail, or mucosal abnormalities were present. A punch biopsy specimen was obtained (Figure 3).
