---

**ABSTRACT:** The inhibition of the PCSK9/LDLR protein-protein interaction is a promising strategy for developing new hypocholesterolemic agents. Familial hypercholesterolemia is linked to specific PCSK9 mutations: the D374Y is the most potent gain-of-function (GOF) PCSK9 mutation among clinically relevant ones. Recently, a lupin peptide (T9) showed inhibitory effects on this mutant PCSK9 form, being also capable to increase liver uptake of low density lipoprotein cholesterol. In this paper, aiming to improve the potency of this peptide, the T9 residues mainly responsible for the interaction with PCSK9<sup>D374Y</sup> (hot spots) were computationally predicted. Then, the “non-hot” residues were suitably substituted by new amino acids capable to theoretically increase the structural complementarity between T9 and PCSK9<sup>D374Y</sup>. The outcomes of this study were confirmed by in vitro biochemical assays and cellular investigations, showing that a new T9 analog is able to increase the LDLR expression on the liver cell surface by 84% at the concentration of 10  $\mu$ M.

---

Proprotein convertase (PC) subtilisin/kexin type 9 (PCSK9) is a serine protease belonging to the PC family that is recognized as a key regulator of circulating low-density lipoprotein (LDL) cholesterol (LDL-c), since physiologically it binds to the LDL receptor (LDLR) and triggers its degradation into lysosomes.<sup>1</sup>

<sup>2</sup> In some pathological conditions (such as familial hypercholesterolemia), PCSK9 displays enhanced LDLR affinity and, lowering the LDLR population on cell membrane, leads to an increase of the circulating LDL-c levels. Consequently, impairing the PCSK9/LDLR interaction, represents a strategy to increase the LDLR population on cell membrane and the consequent reduction of circulating LDL-c. For example, an effective clinical approach to interfere with the PCSK9/LDLR protein-protein (PPI) consists in the use of mAbs, such as *alirocumab* and *evolocumab*, approved for therapy by the American Food and Drug Administration in 2015.<sup>3</sup> Moreover, heparin sulfate-mimetics,<sup>4</sup> peptidomimetics,<sup>5-7</sup> or natural products, such as berberine,<sup>8</sup> have also demonstrated PCSK9 inhibitory activity but, at present, these approaches seem to be far from any clinical application. Recently, despite their known low oral bioavailability, innovative solutions for controlling their metabolism and advanced administration strategies<sup>9-11</sup> have renewed the interest for novel inhibitory peptides.<sup>12,13, 14</sup> In this field, Zhang and co-workers have identified some peptides displaying PCSK9 inhibitory activity,<sup>7,15</sup> whereas we have identified a natural peptide from lupin proteins (LILPKHSDAD, P5), which inhibits PCSK9 in the low micro molar range.

Some PCSK9 mutants result in different physiological behaviors of PCSK9 and familial hypercholesterolemia and additional research efforts are needed to inhibit them. Among them, the D374Y has been proven to be the most potent gain-

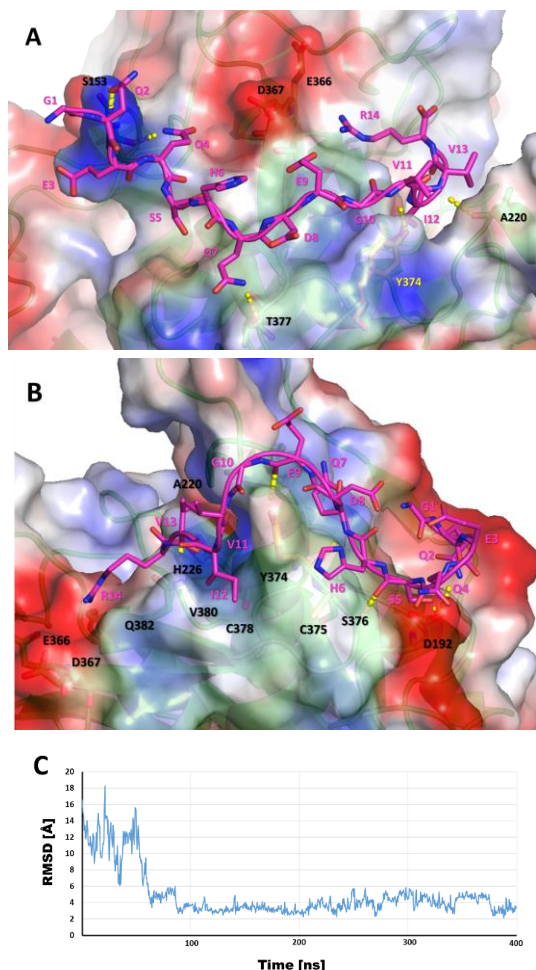

of-function (GOF) PCSK9 mutation,<sup>16, 17</sup> displaying a LDLR binding capacity 25 times greater than the wild type (WT) at the physiological 7.4 pH.<sup>1,18</sup> Interestingly, we have revealed that another lupin peptide (GQEQSHQDEGVIVR, T9) impairs the PCSK9<sup>D374Y</sup>/LDLR interaction with an IC<sub>50</sub> value of 286  $\mu$ M,<sup>19</sup> whereas P5 is practically inactive.

In this paper, aiming to improve the inhibitory effect of T9, an *in silico* procedure was applied in order to predict the binding mode of T9 and the residues mainly responsible for the interaction with PCSK9<sup>D374Y</sup> (hot spots). Then, computational chemistry studies were carried out to identify substitutions of the “non-hot” residues able to increase the structural complementarity between T9 and PCSK9<sup>D374Y</sup>. Finally, a novel T9 analog peptide was evaluated by biochemical assays and cellular investigations, displaying an improved biological activity.

## RESULTS AND DISCUSSION

**PCSK9<sup>D374Y</sup>/T9 complex model.** The geometry of the PCSK9<sup>D374Y</sup>/T9 model was obtained by Ambertools16<sup>20</sup>, modifying the primary structure of the previously developed PCSK9<sup>WT</sup>/T9 computational model.<sup>5</sup> MD simulations accomplished on the resultant model permitted the geometrical equilibration of the new residue in position 374 and permitted to exclude any ligand unbinding events (Figure S1 and Table S1, Supporting information). Figure 1A displays the T9 binding mode before MD simulations whereas, at the end of MD simulations, T9 was stabilized on PCSK9<sup>D374Y</sup> by the following contacts (Figure 1B): 1) H-bonds by the side chains of Q2 and S5 with the one of D192; 2) H-bonds between the backbone of S5, H6 and E9 with the amide group of S376, Y374 and the side

chain of Y374; 3) van der Waals contacts by the aliphatic chain of I12 with PCSK9<sup>D374Y</sup> area shaped by residues C378, V380 and Y374; 4) van der Waals contacts by the side chain of V13 with A220; 5) H-bonds by the C-terminus of R14 with the side chains of Q382 and H226. Finally, the arginine group of R14 produced salt bridges with the negative charged area surrounded by E366 and D367. This binding mode was stably adopted by T9 after the first 100 ns of MD simulations (Figure 1C).

**Figure 1.** Expected T9 binding mode on PCSK9<sup>D374Y</sup> surface, as resulted before (panel A) and after (panel B) MD simulations. Dotted yellow lines highlight the H-bond network while, the enzyme solvent accessible surface, is depicted accordingly with the partial charge of the residues: blue for positive and red for negative areas, respectively. T9 is represented as magenta sticks. Panel C shows the RMSD plot of the T9 backbone atoms with respect to the peptide average structure. The complex backbone was previously aligned with respect to the initial minimized structure.

**Identification of hot spots and design of T9 analogs.** The first step in the rational design of peptide analogs is the identification of the role played by each residue in the template peptide. After recognition of the residues mainly contributing to the binding energy of the interacting peptides (*hot spots*), the “*non-hot*” residues are properly substituted by other amino acids, which may assure a better complementarity between the biological counterparts. Here, the T9 *hot* and *non-hot* spots were identified by performing computational alanine-scanning mutagenesis analysis. Briefly, in the starting PCSK9<sup>D374Y</sup>/T9 complex model,<sup>19</sup> each peptide residue was systematically

mutated into alanine and the resulting complexes were then subjected to MD simulations. Therefore, MM-GBSA calculations were accomplished to obtain estimates of the mutant peptides binding free energy ( $\Delta G^*$ , Table 1).<sup>21, 22</sup> The data in Table 1 suggested that the T9 C-terminus seemed to be essential for the peptide binding, since the substitution of the residues in positions 11, 13, and 14 by alanine led to peptides with estimated binding free energies significantly lower than the starting one.

**Table 1.** Estimated binding free energy values of the peptides under investigations, calculated by MM-GBSA approach ( $\Delta G^*$ , column 3). Mutated peptides were sorted by calculated  $\Delta G^*$  value.

Peptide	Sequence	$\Delta G^*$ value [kcal/mol $\pm$ (Std. Err. of Mean)]
T9	GQE <sup>Q</sup> SHQDEGVIVR	-29.2 $\pm$ 0.8

T9R14A	GQE <sup>Q</sup> SHQDEGVIV <sup>A</sup>	-19.7 $\pm$ 0.6

On the other hand, our estimations also suggested that D8A mutation improved the binding affinity of the resulting peptide, whereas the side chain deletion of the residues in positions 6, 7, 9 and 12 was less effective in improving the peptide-enzyme complementarity. In other words, the original side chains in those positions do not seem to be well adapted to the PCSK9<sup>D374Y</sup> counterpart, since their substitution by a methyl group improved the affinity of the resulting peptides.

The preliminary biochemical evaluation of the T9D8A ability to impair the binding of the PCSK9<sup>D374Y</sup> to its target LDLR was performed by *in vitro* experiments. Results indicated that T9D8A reduced the PCSK9-LDLR PPI by 31.3 $\pm$ 1.79% at the fixed concentration of 100  $\mu$ M. However, T9D8A did not exhibit a clear dose-response profile, when it was tested in the concentration range of 0.1  $\mu$ M - 1 mM (data not shown). Probably, the substitution of a negatively charged side chain (D) by a methyl group (A) altered the peptide folding and the overall physical-chemical properties.

As a consequence, it was hypothesized that the T9 primary structure could be additionally enhanced by the substitution of the amino acids in the “*non-hot*” positions. Accordingly, in a second step, 10,000 possible 6, 7, 9, and 12 T9D8A analogs

were designed and their affinity for PCSK9 were evaluated by the PRIME tool, implemented in the Schrödinger modeling suite. Only two simultaneous sequence mutations were accepted in those calculations, to avoid huge alterations of the original peptide sequence. Finally, the complexes between PCSK9 and the top ranked peptide analogs (i.e. the ten showing the lowest  $\Delta$ Affinity values, Table 2) were submitted to MD simulations and their  $\Delta G^*$  values estimated by MM-GBSA calculations (Table 2).

Surprisingly, whereas by  $\Delta\Delta G$  calculated by PRIME all analogs were hypothetically more active than T9, the majority of them showed MM-GBSA estimations not lower than peptide T9D8A (Table 2). These results were rationalized by the visual inspection of the MD simulations trajectories obtained simulating the T9D8A\_A analog. Here, a conformational instability of the peptide N-terminal end was noted. Therefore, a second stage of PRIME calculations was accomplished, mutating the positions 3, 5, and 7. Once again, two simultaneous changes in the sequence were accepted in the PRIME calculations. The following MD simulations and MM-GBSA calculations on the ten top ranked PCSK9<sup>D374Y</sup>/T9 analogs led to the results collected in Table 3. Here, the T9D8A\_1 peptide acquired the lowest estimated binding free energy value by both approaches. Considerably, this peptide displayed the expected conformational stability, over more than 400 ns-long MD simulations (Figure S2, Supporting information). The attained trajectory suggested that the novel T9 analog was firmly bound on the PCSK9<sup>D374Y</sup> surface (Figure 2) by: 1) two H-bond/salt bridges by the C-terminus (R14) with the PCSK9<sup>D374Y</sup> R215 residue and by K6 with PCSK9<sup>D374Y</sup>D238; 2) van der Waals contacts of the indole ring of W5 and the hydrophobic pocket sized by PCSK9<sup>D374Y</sup> F379, P156 and I369 residues; 3) a H-bond by the NH of M12 and the side chain of PCSK9<sup>D374Y</sup> Y374; 4) a H-bond by the NH of G10 and the backbone of PCSK9<sup>D374Y</sup>F379; 5) the side chains of Q2 and Q4 with the PCSK9<sup>D374Y</sup> N-terminus (S153). Additionally,

an internal salt bridge between the side chains of R3 and E9, strongly limited the conformational freedom of the novel peptide.

**Figure 2.** Expected binding mode of T9D8A\_1 on PCSK9<sup>D374Y</sup> surface, as resulted by docking and MD simulations. Dotted yellow lines depict the H-bond network. The enzyme solvent accessible surface is depicted according to the partial charge of the residues, blue for positive and red for negative areas.

In agreement with these outcomes, peptide T9D8A\_1 was synthesized by the GenScript Company and submitted to biochemical and cellular investigations.

**Biochemical evaluation of the T9D8A\_1 ability to impair the PCSK9<sup>D374Y</sup>-LDLR PPI.** With the aim at evaluating the ability of the T9 analog to reduce the binding of PCSK9<sup>D374Y</sup> to its target LDLR, *in vitro* experiments were performed. More in details, T9D8A\_1 was tested in the concentrations range of 0.1  $\mu$ M- 1 mM. Figure 3A indicates that the T9 analog decreases the PPI in a concentration-response manner with an IC<sub>50</sub> value of 147.8 $\pm$ 3.23  $\mu$ M *versus* the untreated sample (Figure 3A).

**Table 2. Estimated binding affinity values of the new designed peptides (column 1-2), calculated by Prime software ( $\Delta$ Affinity, column 3) and by standard MD/MM-GBSA calculations ( $\Delta G^*$  values, column 4). See supporting material for details.**

This value indicates that the computationally designed T9D8A\_1 is twice more active than T9 in inhibiting the PCSK9<sup>D374Y</sup>/LDLR PPI. In fact, recent results demonstrated that T9 inhibits this PPI by an IC<sub>50</sub> value of 285.6 $\pm$ 2.46  $\mu$ M.<sup>19</sup> Based on these *in vitro* results, further experiments were carried out to characterize in a deeper way the T9 analog ability to modulate the LDLR protein level and activity at cellular level.

**Figure 3.** Panel A) Dose-response effects of peptide T9D8A\_1 on the PPI between PCSK9 and the LDLR. Each point represents the average  $\pm$  s.d. of three experiments in duplicate. T9D8A\_1 peptide improves the ability of HepG2 cells to uptake extracellular LDL (panel B) due to an increase of the LDLR protein level located on the cell surfaces (panel C). Bars represent averages  $\pm$  s.d. of three independent experiments in triplicates. (\*)  $p < 0.05$ , (\*\*)  $p < 0.001$ , and (\*\*\*)  $p < 0.0001$  versus control (C). K9<sup>D374Y</sup>: PCSK9<sup>D374Y</sup>.

**T9D8A\_1 ameliorates the HepG2 ability to uptake LDL increasing the LDLR protein level on the cell surface.** After a 2 h treatment in the presence of PCSK9<sup>D374Y</sup> (4.0  $\mu$ g/mL), the ability of HepG2 cells to uptake the LDL-C from the extracellular environment was reduced by 42.1 $\pm$ 1.6% versus

control, whereas the treatment with 10.0  $\mu$ M T9D8A\_1 totally re-establishes the uptake level up to 102.3 $\pm$ 4.8% versus the untreated sample (Figure 3B). This result strongly suggests that T9D8A\_1 is 35-times more active than T9 from a functional point of view. In fact, when the parent peptide T9 was co-incubated with the same concentration of GOF mutated PCSK9, it restored the uptake level of HepG2 cells only at the concentration of 350  $\mu$ M.<sup>19</sup> This result suggests the potential involvement of an additional mechanism of action by which T9D8A\_1, after permeation of HepG2 cells, might modulate other molecular targets involved in the cholesterol pathway. In fact, the potential ability of the parent peptide T9 to inhibit the HMGCoAR enzyme has been also predicted by computational study.<sup>23</sup> Of course, additional biological experiments are needed to confirm this hypothesis.

The functional results, which are in agreement with the *in vitro* findings, are linked to the ability of the T9 analog to modulate the LDLR protein activity on the hepatic cell surface. By performing in cell-western (ICW) experiments,<sup>19, 24</sup> it was observed that, in the presence of PCSK9<sup>D374Y</sup> (4.0  $\mu$ g/mL), the LDLR protein levels on the HepG2 cell surface was diminished by 39.6 $\pm$ 0.7% versus the control cells and that T9D8A\_1 (10  $\mu$ M) restored the LDLR protein levels up to 83.8 $\pm$ 4.3% (Figure 3C). This is a clear evidence that the increased ability of hepatic cells to uptake the LDL-C from the extracellular environment in the presence of mutated PCSK9 after treatment with T9D8A\_1 is correlated with the augmentation of the activity of the LDLR expressed on the cell surface. Moreover, this result confirms that T9D8A\_1 is 35-times more active than T9, not only from a functional (in terms of HepG2 cell ability to uptake LDL from the extracellular level), but also from a molecular point of view (effect on the active amount of LDLR located on the surface of hepatic cells). In fact, recent results have indicated that peptide T9 (350  $\mu$ M), when co-incubated with GOF mutated PCSK9, restores the LDLR protein level by 74.3  $\pm$  4.4%.<sup>19</sup> For this reason, T9D8A\_1 reestablishes the LDLR protein level by 12.7% more than the parent T9.

In conclusion, the prediction of the binding free energy values of the alanine mutated T9 analogs suggested that the residues in positions 11, 13, and 14 can be considered *hot spots* of the PCSK9<sup>D374Y</sup>/T9 interaction, considering that their mutation into alanine significantly weakened the binding free energy. At the end of this procedure, peptide T9D8A showed the highest estimated affinity than that predicted for the reference peptide T9. A further optimization of the structure, in order to design new and more potent PCSK9<sup>D374Y</sup> inhibitors, was achieved by accomplishing additional mutations into the “*non-hot*” residues, replacing them by different natural amino acids. Applying the MM-GBSA approach and two steps of PRIME calculations, the T9 analog named T9D8A\_1 was designed and synthesized. Experimental *in vitro* tests, as well as cellular assays, confirmed the success of the applied strategy to improve the biological activity of these peptides.

Based on these evidences, the T9D8A\_1 analog possesses great potentiality for further structural optimization, being more biologically active than T9. We are aware that peptides are not usually considered highly bioavailable drugs, however, they are valuable biochemical tools and starting points for designing new small-molecule, such as peptidomimetics, active on the GOF PCSK9<sup>D374Y</sup>.

## EXPERIMENTAL PROCEDURES

**The PCSK9<sup>D374Y</sup>/T9 model and peptide binding free energy estimation.** The PCSK9<sup>D374Y</sup> model were previously developed by us.<sup>19</sup> T9, as well as the new designed analogs, were charged on the N- and C-terminal ends. The rough PCSK9<sup>D374Y</sup>/T9 model was optimized by energy minimization and 400 ns long MD simulations, by *pmemd.cuda* algorithm of Amber 2017 package.<sup>20</sup> Then, the acquired trajectory was examined by visual inspection with VMD,<sup>27</sup> ensuring that the thermalization did not cause any structural distortion. For additional details, see the experimental section of references 5, 19, 25 and 26. MM-GBSA calculations were performed on the mutants PCSK9<sup>D374Y</sup>/T9 complexes. The alanine mutants were built systematically altering the peptide sequence on the PCSK9<sup>D374Y</sup>/T9 complex, by *tleap* module of Ambertools16.<sup>20</sup> The resulting complexes were energy minimized and equilibrated once more by MD simulations, adopting the procedure and the parameters previously applied.<sup>5</sup> In these cases, more than 100 ns of MD simulations were accomplished in the production runs, for each mutant complex. A hundred snapshots were regularly extracted from the trajectories to ensure the lowest standard error in the free energy estimation and the lowest calculation time. The time intervals for the extraction were chosen dividing by 100 the number of frames in which the systems showed the geometrical stability. MM-GBSA calculations were performed by *MM-PBSA.py* module<sup>28</sup> of Amber 2017 package<sup>20</sup>, keeping parameters in the default values. In these calculations, the single trajectory approach was applied and the entropy contributions to the binding free energy, coming from the normal mode analysis, was neglected. For this reason the estimated binding free energy values are termed  $\Delta G^*$ .

**PRIME calculations.** Aiming to improve the affinity of T9D8A, a systematic mutation of the “*non-hot*” positions suggested by alanine scanning analysis were carried out. The ‘protein preparation wizard’ module implemented in the Schrodinger suite for molecular modeling ensured the accuracy of the PCSK9<sup>D374Y</sup>/T9D8A complex conformation equilibrated by MD simulations. In particular, the procedure permitted: (1) to correctly assign the residue protonation state at pH 7.4, (2) to

check the residue completeness and, (3) to eliminate atomic clashes. Then, 10,000 possible peptides were generated by mutations on the selected positions were generated. The resulting complexes were minimized by Prime MM-GBSA, which uses OPLS3<sup>29</sup> as force field and a continuum solvent models to include the solvent effect into the calculations. Finally, affinity maturation functionality in BioLuminate (Prime MM-GBSA, Schrödinger, LLC, New York, NY, 2017) estimated the change in affinity ( $\Delta\Delta G$ ) between PCSK9<sup>D374Y</sup> and the generated peptides with respect to T9D8A.

**Chemicals.** All reagents and kits used for the biological characterization were purchased from commercial sources. More details are reported in Supporting Information.

**PCSK9<sup>D374Y</sup>-LDLR PPI evaluation.** Peptides T9D8A and T9D8A\_1 (0.1  $\mu$ M - 1.0 mM) was investigated using the *in vitro* PCSK9-LDLR binding assay from CircuLex, following the conditions previously described.<sup>19</sup> More details are reported in Supporting Information.

**Cell culture and treatment conditions.** The HepG2 cell line was cultured following the procedure previously described.<sup>30</sup> The HepG2 cells (3 x 10<sup>4</sup>/well) were starved over night (ON) and then, they were treated with 4.0  $\mu$ g/mL PCSK9<sup>D374Y</sup> and 10.0  $\mu$ M T9D8A\_1 in presence of 4.0  $\mu$ g/mL PCSK9<sup>D374Y</sup>, and vehicle (H<sub>2</sub>O) for 2 h at 37 °C in the 5% CO<sub>2</sub> incubator.

**Cell fixation and in cell Western (ICW).** Treated HepG2 cells were fixed in 4% paraformaldehyde for 20 min at room temperature (RT) and samples have been processed for ICW assay following the procedure described in Supporting Information.

**Fluorescent LDL uptake cell-based assay.** The fluorescent LDL uptake cell-based assay was carried out using the procedure previously reported.<sup>5</sup> Additional details are reported in Supporting information.

**Statistical analysis.** Statistical analyses were carried out by *t*-student (Graphpad Prism 6). Values were expressed as means  $\pm$  *s.d.*; *P-values* < 0.05 were considered significant.

This research was supported by the Fondazione Banca del Monte di Lombardia (PV).

## ACKNOWLEDGMENT

G.G. acknowledges the CINECA and the “Regione Lombardia” award under the LISA initiative, for the availability of high

performance computing resources and support. We are indebted to Carlo Sirtori Foundation (Milan, Italy) for having provided part of equipment used in this experimentation.
