Abstract: Nowadays, the strong demand for adequate nutrition is accompanied by concern about environmental pollution and there is a considerable emphasis on the recovery and recycling of food by-products and wastes. In this study, we focused on the exploitation of olive pomace as functional ingredient in biscuits and bread. Standard and enriched bakery products were made using different flours and fermentation protocols. After characterization, they were in vitro digested and used for supplementation of intestinal cells (Caco-2), which underwent exogenous inflammation. The enrichment caused a significant increase in the phenolic content in all products, particularly in the sourdough fermented ones. Sourdough fermentation also increased tocol concentration. The increased concentration of bioactive molecules did not reflect the anti-inflammatory effect, which was modulated by the baking procedure. Conventionally fermented bread enriched with 4% pomace and sourdough fermented, not-enriched bread had the greatest anti-inflammatory effect, significantly reducing IL-8 secretion in Caco-2 cells. The cell metabolome was modified only after supplementation with sourdough fermented bread enriched with 4% pomace, probably due to the high concentration of tocopherol that acted synergistically with polyphenols. Our data highlight that changes in chemical composition cannot predict changes in functionality. It is conceivable that matrices (including enrichment) and processing differently modulated bioactive bioaccessibility, and consequently functionality.

## Highlights:

The magnitude of the increase in phenols due to olive pomace is not proportional to the biological effect

Bioactive bioaccessibility is an important determinant of food functionality and it is modulated by processing

Bread-making procedures must be carefully modulated based on ingredients

At tested concentration polyphenols do not modulate metabolome in Caco-2 cells

## 1. INTRODUCTION

Olive oil production, an agro-industrial activity of vital economic significance for many Mediterranean countries, is associated with the generation of large quantities of wastes and by products (Berbel & Posadillo, 2018) and there is an increasing interest in using them in food products as functional ingredients. Despite the high concentration of phenolic compounds in the olive fruit, only 2% of the initial concentration is found into virgin olive oil (VOO), while the remaining fraction is found in the olive mill wastewater (OMW) (approximately 53%) and in the olive pomace (OP) (approximately 45%). OMW and OP have a different phenolic profile. Oleuropein is abundant in the OP (up to 0.9%) (Sanchez de Medina, Priego-Capote, & Luque de Castro, 2012) and it is absent in OMW due to enzymatic hydrolysis during the olive oil extraction (Cardinali et al., 2012).

Oleuropein, tyrosol and their derivatives are supposed to be the main culprits of the health benefits related to its consumption (Karkovic Markovic, Toric, Barbaric, & Jakobusic Brala, 2019), this making OP a potential low-cost starting material rich in bioactive phenolics (Antonia Nunes et al., 2018). The use of OP could represent an innovative and low-cost strategy to formulate healthier and value-added foods, and bakery products are good candidates for enrichment. In fact, they are consumed all over the world, and a wide variety of bakery product such as bread, biscuits, crackers, breadsticks, and others can be found on supermarket shelves.

The nutritional value of bakery products can be improved by different strategies including the use of by-products as ingredients (Boubaker, Omri, Blecker, & Bouzouita, 2016). Beyond enrichment, the development of innovative bakery food can be linked to the production process. As example, sourdough fermentation has been shown to modulate the functional features of leavened baked goods (Gobbetti, De Angelis, Di Cagno, Calasso, et al., 2019). Enrichment and modification of the production process could act synergistically and allow the development of functional products.

To verify it, in this study different bakery products (biscuits and breads) were made using different flours and fermentation protocols and eventually enriched with defatted olive pomace (DOP). Since the supposed functionality of the innovative products could not be assessed simply evaluating their chemical composition and changes linked to digestion had to be carefully considered, after chemical characterization products were *in vitro* digested. To test the effects in a biological system, the digested fraction with a molecular weight compatible to absorption was used for supplementation of intestinal cells, which underwent exogenous inflammation. Cultured enterocytes were used as model system since *in vivo* they are in direct contact to the digestion products. Given that in a recent study we evidenced the positive effect of a polyphenols rich extract from olive pomace on

78 inflammation and cell metabolome in intestinal cell culture (Di Nunzio, Picone, et al., 2018), the  
1  
279 effects of supplementation with the digested bakery products was investigated measuring cytokines  
3  
4 secretion and evaluating the modification of cell metabolome by nuclear magnetic resonance  
5  
6 (NMR) spectroscopy.

## 2. MATERIAL & METHODS

The experimental design of the study is depicted in Figure 1.

### 2.1. Chemicals

Dulbecco's modified Eagle's medium (DMEM), penicillin, streptomycin, and Dulbecco's phosphate-buffered saline (DPBS) were purchased from Lonza (Basel, Switzerland). All other chemicals and solvents were of the highest analytical grade from Sigma-Aldrich Co. (St. Louis, MO, USA).

### 2.2. Fermentation and baking processes

Whole einkorn flour (*Triticum monococcum* L. var. Monlis) and whole wheat flour (*Triticum aestivum* L.) were provided by Prometeo (Urbino, Italy). DOP powder was provided by ISANATUR SPAIN S.L. (Puente La Reina, Spain). DOP powder was obtained from the by-product of olive oil extraction by drying and defatting based on the patent WO2013030426 with further developments to increase the process sustainability.

Six different types of bakery products were prepared and tested:

- a) biscuits (BIS) made with whole einkorn flours, with or without 2.5% DOP;
- b) conventional fermented bread (CFB) made with whole wheat flours with or without 4% DOP;
- c) sourdough fermented bread (SFB) made with whole wheat flours with or without 4% DOP.

DOP concentration for enrichment was chosen based on the limit of organoleptic acceptance in consumer preference test (data not shown).

For sourdough preparation, a 10% (fresh weight basis - fwb) mixed-strain containing *Lb plantarum* 98A, *Lb. sanfranciscensis* BB12, *Lb. brevis* 3BHI, and 3% (fwb) of *S. cerevisiae* LBS was added to the dough and fermented at 32 °C for 24 h to obtain a mature sourdough. The microbial load in mature sourdough was approximately 10<sup>9</sup> colony forming units (CFU)/g for LAB and 10<sup>7</sup> CFU/g

112 for *S. cerevisiae*. For conventional fermentation, 14% (fwb) of *S. cerevisiae* LBS was added to the  
113 final dough for 1.5 h of leavening at 32 °C.

114 The recipes of the bakery products are reported in Table 1. Biscuits and breads were cooked in oven  
115 at 180 °C for 25 minutes and 200 °C for 30 minutes, respectively. After baking, they were cooled at  
116 room temperature, cut into small pieces and stored at -18 °C until analysis. Each bakery product  
117 was prepared in triplicate on separate days.

### 118 119 2.3. Polyphenol extraction and determination by HPLC-DAD-MS

120  
121 The phenolic fractions were obtained by solid-liquid extraction as described by Marzocchi *et al.*  
122 (Marzocchi *et al.*, 2017) with slight modifications. Briefly, 3 g of powdered sample were defatted  
123 by stirring with 30 mL of hexane for 30 minutes. After removing supernatant, the defatted pellet  
124 was extracted with 30 mL of ethanol/water (4:1 v/v) in ultrasonic bath at 40 °C for 15 minutes.  
125 After centrifugation at 3500 rpm for 15 min, the supernatant was removed, and the extraction was  
126 repeated. Supernatants were pooled, evaporated at 35 °C under vacuum and reconstituted with 6 mL  
127 of water/methanol (1:1 v/v). The final extracts were filtered with regenerated 0.2 µm cellulose  
128 filters (Millipore, Bedford, MA, USA) and stored at -18 °C until analysis.

129 Polyphenol profile was determined using an Agilent 1200-LC system (Agilent Technologies, Palo  
130 Alto, CA, USA) equipped with vacuum degasser, autosampler, binary pump, HP diode-array, UV-  
131 VIS detector and mass spectrometer detector as previously described (Di Nunzio, Toselli, Verardo,  
132 Caboni, & Bordoni, 2013). Separations were carried out on a reverse phase column Poroshell 120  
133 SB-C18 (3x100 mm, 2.7 µm) from Agilent Technologies (Palo Alto, CA, USA) and the  
134 chromatogram was registered at 280 nm. Compounds were identified by analysing their UV and  
135 MS spectra and quantified by DAD detection. The individual phenolic compounds were quantified  
136 by their UV absorbance against external standards using tyrosol, caffeic acid, ferulic acid,  
137 chlorogenic acid, oleuropein, verbascoside and rutin at 280 nm for the different class of phenols.  
138 Results are expressed as mg/Kg bakery product.

### 139 140 2.4. Tocol determination by HPLC-FLD

141  
142 Lipids were extracted from bakery products as previously reported (Boselli, Velazco, Caboni, &  
143 Lercker, 2001). One hundred µg of lipids were dissolved in 1 ml hexane and filtered through a 0.2  
144 µm nylon filter, then 2.5 µL were injected in a HPLC 1200 series equipped with a fluorimeter  
145 detector ( $\lambda_{ex} = 290$  nm,  $\lambda_{em} = 325$  nm) (Agilent Technologies, Palo Alto, CA, USA). Separation of

146 tocopherols was performed by a HILIC Poroshell 120 (3x100 mm, 2.7  $\mu$ m) from Agilent  
147 Technologies (Palo Alto, CA, USA) in isocratic conditions using an n-hexane/ethyl acetate/acetic  
148 acid (97.3:1.8:0.9 v/v/v) mobile phase. The flow rate was 0.8 mL/min. Tocopherols were identified  
149 by co-elution with the **corresponding** standards. The calibration curve used for quantification was  
150 constructed with  $\alpha$ - tocopherol standard solutions. Results are expressed as mg/Kg bakery product.

151

## 152 2.5. *In vitro* digestion

153

154 The digestion process was performed on 50 g of bakery product or water (blank digestion) for 245  
155 min (5 min of oral, 120 min of gastric and 120 min of intestinal digestion) at 37 °C, according to the  
156 INFOGEST standardized protocol (Minekus et al., 2014) as described in Valli *et al.* (Valli, Taccari,  
157 Di Nunzio, Danesi, & Bordoni, 2018). During *in vitro* digestion, simulated saliva (containing 75  
158 U/mL  $\alpha$ -amylase), simulated gastric juice (containing 2000 U/mL pepsin) at acid pH, and simulated  
159 pancreatic juice (containing 10 mM bile and 100 U/mL pancreatin) at neutral pH **were added**.  
160 **Digested** solutions were centrifuged at 50.000 g for 15 min, and the supernatants filtered with 0.2  
161  $\mu$ m membranes. To separate compounds which size is small enough to be potentially absorbable  
162 through the intestinal mucosa, an aliquot was sequentially ultra-filtered with Amicon Ultra  
163 (Millipore, Burlington, MA, USA) at 3 kDa of molecular weight cut-off (low molecular weight  
164 fraction, LMWF). Each product was digested three times, and the resulting LMWF were mixed and  
165 frozen at -18 °C until use.

166

## 167 2.6. *Caco-2* cell culture and supplementation

168

169 Caco-2 cells were maintained at 37 °C, 95% air, 5% CO<sub>2</sub> in DMEM supplemented with foetal  
170 bovine serum (10% v/v), non-essential amino acids (1% v/v), 100 U/mL penicillin and 100  $\mu$ g/mL  
171 streptomycin. Once a week cells were seeded at  $9 \times 10^3$  cells/mL into a new 75 cm<sup>2</sup> flask, and  
172 medium was refreshed every 48h (Antognoni et al., 2017).

173 For experiments, Caco-2 cells were seeded in 24-well at  $1 \times 10^5$  cells/well concentration  
174 (cytotoxicity and inflammation assays) or in 100 mm Petri dishes at  $2.7 \times 10^6$  cells/dish (NMR  
175 assay) and grown for 21 days. Complete differentiation was assessed by measuring the trans  
176 epithelial electric resistance of the cell monolayer using the Millicell ERS apparatus (Millipore,  
177 Burlington, MA, USA).

178 In preliminary experiments, to assess cytotoxicity in basal conditions (i.e. without any inflammatory  
179 stimulus), cells were supplemented for 24h with serum-free DMEM containing different

180  
181  
182  
183  
184  
185

180 concentration of LMWF (2.5, 5, 10, 20  $\mu\text{L}/\text{mL}$  medium). Cytotoxicity was assessed as reported  
181 below. In further experiments cells were supplemented with the highest LMWF concentration  
182 having no cytotoxic effects (5 $\mu\text{L}$  of LMWF/mL medium). To avoid interference due to the vehicle,  
183 some cells were supplemented with the same amount of LMWF from blank digestion (B), while  
184 other cells received no supplementation (unsupplemented - US).  
185 Concomitant to LMWF supplementation, inflammation was induced exposing cells to interleukin 1  
186 beta (IL-1 $\beta$ ) at 10 ng/mL for 24 h.

187

## 188 2.7. Cytotoxicity evaluation

189

190 LMWF cytotoxicity was evaluated by assessing cell viability with the methylthiazolyldiphenyl-  
191 tetrazolium bromide (MTT) assay and by microscopic examination. Cell viability was determined  
192 by conversion of the MTT salt to its formazan product detected at 560 nm using a Tecan Infinite  
193 M200 microplate reader (Tecan, Männedorf, Switzerland) (Di Nunzio, Bordoni, Aureli, Cubadda,  
194 & Gianotti, 2018), and it was expressed as optical density (O.D.). Light microscopy examination of  
195 cell morphology and monolayer integrity was performed using an inverted confocal light  
196 microscopy model IB (Exacta Optech, Modena, Italy) using 10X, 25X and 40X as magnification.

197

## 198 2.8. Cytokines secretion

199

200 Concentration of the pro- and anti-inflammatory cytokines interferon gamma (IFN $\gamma$ ), interleukin 1  
201 alpha (IL-1 $\alpha$ ), IL-1 $\beta$ , interleukin 2 (IL-2), interleukin 4 (IL-4), interleukin 6 (IL-6), interleukin (IL-  
202 8), interleukin 10 (IL-10), interleukin 12 p70 (IL-12p70), and tumour necrosis factor alpha (TNF $\alpha$ )  
203 was estimated in the cell media by the multiplex sandwich ELISA Ciraplex (Aushon, Billerica,  
204 MA, USA) following the manufacturer's instructions. 96-well plates pre-spotted with protein-  
205 specific antibodies were used and luminescent signals were detected by Cirascan<sup>TM</sup> Imaging  
206 System.

207 IL-8 concentration was also estimated in cell media using AlphaLISA kits (Perkin Elmer Inc.,  
208 Waltham, MA, USA) following the manufacturer's instructions (Valli et al., 2016). We used 96-  
209 microwell plates that were read using an EnSpire<sup>TM</sup> plate reader (Perkin Elmer Inc., Waltham, MA,  
210 USA). Results were expressed as pg/mg protein.

211

## 212 2.9. Protein content determination

213

214

215

216

217

214 Cells were washed with cold DPBS, lysed with 500  $\mu$ L of cold Nonidet P-40 (0.25% v/v in DPBS),  
1  
215 incubated on ice with shaking for 30 min and centrifuged at 14.000g for 15 min. Supernatants were  
2  
216 collected and protein content was determined by Comassie assay (Di Nunzio, Valli, & Bordoni,  
3  
4  
217 2016), using bovine serum albumin as standard.

## 2.10. HR $^1$ H-NMR

Cells were washed with ice-cold DPBS and scraped off. The pellet lysed by sonication and centrifuged at 21.000g for 10 min at 4 °C. Five hundred  $\mu$ l of supernatant were added to 10  $\mu$ L of a D<sub>2</sub>O solution of 100 mM 2,2-dimethyl-2-silapentane-d<sub>6</sub>-5-sulfonic (d<sub>6</sub>-DSS) with a final concentration in the NMR tube of 9.09 mM.  $^1$ H-NMR spectra were recorded at 298 K on a Bruker US+ Avance III spectrometer operating at 600 MHz, equipped with a BBI-z probe and a B-ACS 60 sampler for automation (Bruker BioSpin, Karlsruhe, Germany). The HOD residual signal was suppressed by applying the Carr–Purcell–Meiboom–Gill spin-echo pulse sequence with a pre-saturation sequence. Each spectrum was acquired using 32 K data points over a 7183.908 Hz spectral width (12 ppm) and adding 256 transients. A recycle delay of 5 s and a 90° pulse of 11.190  $\mu$ s were set up. Acquisition time (2.28 s) and recycle delay were adjusted to be 5 times longer than the longitudinal relaxation time of the protons under investigation, which was not longer than 1.4. Data were Fourier transformed and phase and baseline corrections were automatically performed using TopSpin version 3.0 (Bruker BioSpin, Karlsruhe, Germany). Signals were identified by comparing their chemical shift and multiplicity with Chenomx Profiler software data bank (ver. 8.1, Edmonton, Canada) and data in the literature (Picone et al., 2013).

## 2.11. Statistical analysis

Statistical differences were determined by the one-way analysis of variance (ANOVA) followed by Tukey's post hoc-test considering  $p < 0.05$  as significant, and by the Student's t-test. NMR spectra processing and PCA analyses were performed using R computational language (ver. 3.5.3). Each  $^1$ H NMR spectrum was processed by means of R scripts developed in-house. All other statistical analyses were performed using Prism software ver. 5.0 (GraphPad, San Diego, CA, USA).

The nutritional composition of the bakery products is given in Table 2, according to producer's analysis.

The phenolic profile of bakery products and a representative UV chromatogram of the SFB4% phenolic compounds are reported in Table 3 and Figure 2, respectively. The total phenol content was greater in all DOP-enriched products than the corresponding controls and was greater in SFB than in other products.

Tocol concentration of bakery products and a representative chromatogram of the BIS2.5% tocol profile are reported in Table 4 and Figure 3, respectively. The enrichment with DOP caused a significant increase in total tocol content, due mainly to  $\beta$ -tocopherol concentration, only in SFB.

### 3.2. *Effects in Caco-2 cells*

#### 3.2.1 *Experimental set-up in basal condition*

In cells supplemented with 10  $\mu\text{L}/\text{mL}$  and 20  $\mu\text{L}/\text{mL}$  CFB4% and SFB0% light microscopic examination revealed a deep change of cellular morphology and a loss of cell monolayer integrity (Figure 4). In addition, an increase in MTT conversion was observed (Figure 5). It was probably related to an enhanced mitochondrial mass and electron transport system activity due to the increased energy requirements under critical condition (Choi, Roche, & Caquet, 2001; Lee, Yin, Chi, & Wei, 2002). Regardless the type of LMWF, the 5  $\mu\text{L}/\text{mL}$  concentration had no effect on cell viability, morphology and monolayer integrity and it was therefore used for supplementation in further experiments.

To select the most appropriate inflammatory stimulus, Caco-2 cells were supplemented for 24h with two different concentrations of lipopolysaccharide (LPS) (100 ng/mL and 500 ng/mL), IL-1 $\beta$  (10 ng/mL and 50 ng/mL), and TNF $\alpha$  (10 ng/mL and 50 ng/mL) alone or in combination (LPS 100 ng/mL + IL-1 $\beta$  10 ng/mL + TNF $\alpha$  10 ng/mL and LPS 500 ng/mL + IL-1 $\beta$  50 ng/mL + TNF $\alpha$  50 ng/mL). The onset of inflammation was assessed by measuring the secretion of IL-6 and IL-8 using the AlphaLISA kit assay (Figure 6A and 6B, respectively). IL-1 $\beta$  supplementation at 10 and 50 ng/mL significantly enhanced IL-6 and IL-8 secretion, without any additive effect due to combination with TNF $\alpha$  and LPS. On this basis, 10 ng/mL IL-1 $\beta$  were used as inflammatory stimulus in further experiments.

In basal condition, secretion of most cytokines was below the detection limit. IL-8 was by far the most represented one, and supplementation with B-LMWF did not **modify** its concentration (Table 5).

Caco-2 cells were stressed by adding 10 ng/mL IL-1 $\beta$ , and the different LMWF were co-supplemented to evaluate their putative anti-inflammatory effect (Table 5). Inflammation caused a significant increase of IL-6 and IL-8 secretion in both US and B supplemented cells compared to basal counterparts ( $p < 0.001$ ). Comparing inflamed cells, IL-8 secretion was significantly lower in CFB4% and SFB0% cells than in US. In CFB4%, it was also lower than in B supplemented enterocytes. All supplementation except BIS2.5% and CFB0% decreased IL-6 secretion.

A relatively high within-group variability was evidenced evaluating cytokine secretion with multiplex sandwich ELISA Ciraplex. Since intra- and inter-assay reproducibility of multiplex assays is sometimes lower than in singleplex assays (Tighe, Ryder, Todd, & Fairclough, 2015), to better investigate the effect of supplementation we measured the secretion of the most expressed cytokine IL-8 also using a singleplex assay, which almost confirmed previous results (Figure 7). In basal condition, supplementation with LMWF from B digestion did not modify IL-8 secretion, which was strongly increased by the exposure to the inflammatory stimulus in both US and B cells compared to corresponding basal values ( $p < 0.001$  in both cases). In inflamed condition, all supplementations except CFB0% reduced IL-8 secretion. In CFB4% supplemented cells, IL-8 secretion was also lower than in B supplemented ones.

### 3.2.3. *Effect on the metabolome*

Metabolome analysis was performed on the cell lysate. Before statistics, each  $^1\text{H}$  NMR spectrum was processed by means of scripts developed in-house in R language. Chemical shift referencing was performed by setting the DSS signal to 0.00 ppm. Moreover, the alignment of the spectra was improved using the *iCoshift* tool (Savorani, Tomasi, & Engelsen, 2010) available at <http://www.models.life.ku.dk/algorithms/>. The following spectral regions were removed prior to data analysis: the regions including only noise (the spectrum edges between 11.00 and 9.00 ppm and between 0.8 and -1.00 ppm) and the NMR signal which **was** strongly affected by the residual solvent peak (water between 4.50 and 5.00 ppm). After the Fourier transformation and prior to multivariate analysis, data underwent to a pre-statistical improvement. First, spectra were normalized to the unit area to reduce possible dilution effects (Craig, Cloarec, Holmes, Nicholson, & Lindon, 2006). Then, to avoid the effect of peaks misalignments among different spectra due to

316 variations in chemical shift of signals belonging to some titratable acids, a points reduction by the  
317 “spectral binning” was performed (Gartland, Beddell, Lindon, & Nicholson, 1991) by subdividing  
318 the spectra into 410 bins each integrating 100 data points (0.0183 ppm each). A representative <sup>1</sup>H  
319 NMR spectrum of SFB4% cell lysate is reported in Figure 8.

320 Principal component analysis (PCA) performed on 410 bins is reported in Figure 9. PC1 vs PC2  
321 accounted for 86% of the total variance, which was mainly located along PC1 (74%). In order to  
322 determine variables encompassing most of the discriminative information, bins with a loading value  
323 greater than 1% of the overall standard deviation of all loading values were selected (Picone et al.,  
324 2018) on the most important bins along PC1 and PC2. The main metabolites involved in the  
325 discrimination among groups were glucose (Glu), lactate (Lac), sn-glycero-3-phosphocholine  
326 (snG3pc), o-phosphocholine (oPc), myo-inositol (myI), choline (Cho), alanine (Ala) and ethanol  
327 (Eth).

328 In basal condition, no differences were detected between US and B supplemented cells.  
329 Inflammation caused increased lactate signals in US cells compared to basal counterparts, while no  
330 differences were detected in B cells. Supplementation did not cause any modification in the  
331 metabolome of inflamed cells, except an increase of Cho and myI and a decrease of snG3pc signals  
332 observed in SFB4% cells (Table 6).

333

#### 334 4. DISCUSSION

335

336 In conventional **bakery** products, total phenol content reflected the type of flour and fermentation  
337 used for baking. The higher total phenol content observed in CFB0% than SFB0% **was probably**  
338 **due** to the degradation of the cell wall structure by microbial enzymes during yeast fermentation. **As**  
339 **reported by Angelino et. al. (Angelino et al., 2017)**, this could cause the release of the aglycones  
340 from their glycoside linked to the fibres, making them more available for hydroalcoholic extraction.  
341 The higher total tocol content in conventional biscuits than breads **were** justified by the use of extra  
342 virgin oil for BIS preparation.

343 **Enrichment with DOP increased the concentration of the typical olive oil polyphenols in all bakery**  
344 **products. In enriched products, total phenolics were 140% (BIS), 115% (CFB) and 206% (SFB)**  
345 **compared to not-enriched counterparts. In a recent work (Cedola, Cardinali, D'Antuono, Conte, &**  
346 **Del Nobile, 2020), OMWW and olive paste were used to improve the chemical quality of bread and**  
347 **pasta. Enrichment with OMWW slightly improved phenolic contents and antioxidant activity,**  
348 **which were ameliorated by olive paste addition. It was not possible to compare results by Cedola et**  
349 **al (Cedola et al., 2020) to our results since they simply evaluated the theoretical phenolic content**

350  
351  
352  
353  
354  
355

350 and not the actual phenolic content and profile of bakery products. Of note, in their study olive  
351 paste negatively influenced the sensory properties due to a very bitter and spicy taste, while in our  
352 study DOP concentration for enrichment was chosen based on the limit of organoleptic acceptance  
353 in consumer preference test. Fermented olive paste was also used to increase the functionality of  
354 Italian bakery products *taralli* (Durante et al., 2019). In that study, the increase of total phenolics  
355 was higher than in the present study, and it was justified by a higher addition of fermented olive  
356 paste (200 g/kg flour) than of DOP in the present study (70 g/kg flour in BIS and about 40 g/kg  
357 flour in CFB and SFB). Organoleptic characteristics of *taralli* were not evaluated.

358 Enrichment with DOP did not increase tocol concentration in BIS and CFB probably due to  
359 defatting, which is known to remove most of vitamin E from olive pomace (Rosello-Soto et al.,  
360 2015). It is conceivable that sourdough fermentation caused the increase of tocol concentration in  
361 SFB4%, as already reported by Gianotti et al (Gianotti et al., 2011).

362 To evaluate their effect in a biological system, bakery products were *in vitro* digested and the  
363 LMWFs were used to supplement Caco-2 cells. To avoid misleading results (Di Nunzio et al.,  
364 2017), potential cytotoxicity of LMWF was assessed prior to other experiments. As previously  
365 reported (Van De Walle, Hendrickx, Romier, Larondelle, & Schneider, 2010), IL-8 was the main  
366 cytokine secreted by Caco-2 cells, and secretion was significantly increased upon the inflammatory  
367 stimulus. In inflamed cells, supplementation with blank digesta reduced the secretion of IL-8  
368 secretion to a similar extent to supplementation with digested bakery products. This confirms the  
369 anti-inflammatory effects of bile acids (Ward et al., 2017) and indicates that the observed effect was  
370 mainly due to the vehicle.

371 Only LMWF from digested CFB4% and SFB0% actively contributed to the overall anti-  
372 inflammatory effect. The effectiveness of CFB4%, which showed the highest phenol concentration,  
373 is easily explained. On the contrary, it is difficult to give a motivation to the greater anti-  
374 inflammatory activity of SFB0%, which had a lower phenol and tocol content than the ineffective  
375 SFB4%. We hypothesize that the interactions between matrices (including DOP enrichment) and  
376 processing differently modulated bioactive bioaccessibility, i.e. the percentage that is made  
377 available for absorption during digestion, in conventional and experimental breads. This matrix and  
378 processing effect were already reported in different food. (Bordoni et al., 2011; Ferranti et al., 2014;  
379 Marcolini et al., 2015). Of note, the cytotoxic effect of the highest concentration of CFB4% and  
380 SFB0% and not SFB4% confirms that a higher number of active molecules was released from the  
381 matrix.

382 Using an untargeted approach, we evidenced that inflammation had no effect on cell metabolome in  
383 our experimental conditions. As well, in inflamed condition cell metabolome was not modified by

384 any supplementation except SFB4%, which caused a decrease in snG3pc and an increase in myI and  
385 Cho concentration. In our previous study, olive polyphenols supplementation caused a huge dose-  
386 related perturbation of Caco-2 cells metabolome (Di Nunzio, Picone, et al., 2018). In that study, the  
387 amount of olive polyphenols used for supplementation was 100 – 1000 times higher than in the  
388 present one, and this confirms that polyphenol concentration is a main determinant of metabolome  
389 perturbation. Of note, the present study reports the effect of an enriched food, which polyphenol  
390 concentration was based on organoleptic acceptance of the product. We speculate that in SFB4%  
391 the high concentration of tocopherol acted synergistically with polyphenols. The increase of MyI  
392 and Cho, which are important precursors of plasma membrane structured lipids (Tayebati, Marucci,  
393 Santinelli, Buccioni, & Amenta, 2015; Thomas, Mills, & Potter, 2016) suggests changes in cell  
394 membrane integrity (Ricks et al., 2019; Zeisel, Klatt, & Caudill, 2018) induced by polyphenols and  
395 tocopherol. Polyphenols, including olive phenols, incorporate into the lipid bilayer inducing  
396 biophysical changes (phospholipid re-packing) and altering the membrane structure (de Granada-  
397 Flor, Sousa, Filipe, Santos, & de Almeida, 2019; Saija et al., 1998; Saija & Uccella, 2000;  
398 Verstraeten, Fraga, & Oteiza, 2015). As well, tocopherol influences the phase behaviour of lipid  
399 bilayer affecting viscosity characteristics and structural transitions of plasmatic membrane (Belov,  
400 Mal'tseva, & Pal'mina, 2011; Wang & Quinn, 1999, 2000).

401 In summary, our results indicate that both the enrichment with a by-product of olive oil production  
402 and the baking process influence the functionality of the final products. Several phenolic  
403 compounds found in the enriched bakery products possess biological properties (Mateos, Sarria, &  
404 Bravo, 2019), so it is not possible to assess which of them was the major determinant of the effects  
405 observed at the Caco2 cell level. It is very likely that different phenols acted synergistically. Beside  
406 enrichment, the type of fermentation might influence the functional properties of bread, probably by  
407 modifying bioaccessibility of phenolic compounds, as previously reported by Katina *et al.*, (Katina  
408 et al., 2012) and Wang *et al.* (Wang, He, & Chen, 2014). Although the recent review by Gobbetti *et*  
409 *al.* (Gobbetti, De Angelis, Di Cagno, Polo, & Rizzello, 2019) reported numerous evidences that  
410 qualified the sourdough fermentation as the most sustainable and powerful process to exploit the  
411 technological, nutritional and functional features of bakery, the present work highlights that it could  
412 counteract the effect of specific enrichments. Therefore, it can be concluded that there are no  
413 absolute best techniques and bread-making must be carefully modulated based on ingredients. The  
414 effect of processing on phenolics content was clearly evidenced also in pasta enriched with DOP,  
415 where cooking significantly decreased the concentration of bioactives (Simonato, Trevisan, Tolve,  
416 Favati, & Pasini, 2019).

417 Results herein reported highlight that the increased concentration of bioactive molecules in the food  
418 is not enough to guarantee its functionality in biological systems. Bioaccessibility must be carefully  
419 considered, and effectiveness should be demonstrated. To our knowledge, the present study is the  
420 first one not limited to evidencing the increase of phenolics and antioxidant potential in enriched  
421 bakery products but also evaluating the effect of the digested products in cultured cells. Notably, the  
422 contribution of the gut microbiota to polyphenols transformation was not considered in our model  
423 system, and we are aware that results obtained *in vitro* do not exactly mirror the *in vivo* effect.  
424 Anyway, although clinical intervention studies are the gold standard to verify the health effect of  
425 foods, *in vitro* studies can give useful preliminary indications and may represent the first step  
426 towards the formulation of effective functional food.

## Funding

This study was supported by the EU Project EcoPROLIVE “Ecofriendly PROcessing System for the full exploitation of the OLIVE health potential in products” (grant agreement no. 635597).

## Author contributions

M.D.N. performed the experiments on cell culture with E.C. and wrote the draft manuscript; G.P. carried out NMR and multivariate statistical analysis; F.P. performed HPLC analyses; A.B., M.F.C., F.C. and A.G. designed and supervised the study. All Authors critically contributed to the manuscript writing.

## Conflicts of interest

The authors declare no conflict of interest.

Data are expressed as pg/mg of protein and are mean  $\pm$  SD of four samples from two independent experiments. Statistical analysis was performed by the Student's t-test to compare US and B cells in basal condition (<sup>†</sup> p<0.05), and US and B inflamed cells with the corresponding basal counterparts (IL-6 and IL-8: p<0.001). Inflamed supplemented cells were compared by one-way ANOVA (IL-6 and IL-8: p<0.001) using Tukey's post-hoc test. Different letters in the same row indicate significant differences (at least p <0.05). n.d. = not detectable. The limit of detection was 4.75 fg/ml, 0.177 pg/ml, 40.5 fg/ml, 9.72 fg/ml, 59 fg/ml, 0.25 pg/ml, 0.74 pg/ml for IFN $\gamma$ , IL-1 $\alpha$ , IL-2, IL-4, IL-10, IL-12p70, and TNF $\alpha$ , respectively. **US: unsupplemented; B: blank; BIS0%: biscuits made without defatted olive pomace (DOP); BIS2.5%: biscuits made with 2.5% DOP; CFB0%: conventional fermented bread made without DOP; CFB4%: conventional fermented bread made with 4% DOP; SFB0%: sourdough fermented bread without DOP; SFB4%: sourdough fermented bread made with 4% DOP; IFN $\gamma$ : interferon gamma; IL-1 $\alpha$ : interleukin 1 alpha; IL-1 $\beta$ : interleukin 1 beta; IL-2: interleukin 2; IL-4: interleukin 4; IL-6: interleukin 6; IL-8: interleukin 8; IL-10: interleukin 10; IL-12p70: interleukin 12 p70; TNF $\alpha$ : tumour necrosis factor alpha.**
